

Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

- + *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.
- + *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.
- + *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.
- + *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página <http://books.google.com>

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

THE ENGLISH MECHANIC:

A Record of Mechanical Invention, Scientific and Industrial Progress,
Building, Engineering, Manufactures, Arts, &c.

VOL. II.—No. 27.]

FRIDAY, SEPTEMBER 29, 1865.

[PRICE ONE PENNY.]

SLEIGH'S HYDROSTATIC ROTARY ENGINES.

HYDROSTATIC ROTARY ENGINES.

Letters patent have been granted to Mr. B. W. A. Sleigh, of 7, Alfred-place, Bedford-square, for improvements in the means of obtaining continuous rotary motion by means of a hydrostatic rotatory motive power engine for the propulsion of machinery.

The engine is placed upon a bed plate of metal, A, A, A, A, resting upon, if necessary, upright standards or bearers, between which revolve and work the parts of the engine beneath the bed plate. In the first place there are bolted down upon the foundation plate in a horizontal position, four ram cylinders, 1, 2, 3, 4, at the end of which are attached their respective series of pump plunger cylinders, 5, 6, 7, 8. Nos. 1 and 2 ram and pump plunger cylinders are placed with a space between, parallel

to each other, as are also Nos. 3 and 4, only to the rear of the former. In each cylinder is a metal ram, 9, 10, 11, 12, and each cylinder is for a space within its mouth grooved out in a recess so as to form a stuffing box, through which the rams, 9, 10, 11, 12 pass outwards in giving their strokes, and then retire inwards after delivering the same. One set of ram cylinders, 1 and 2, with their rams, 9 and 10, face a main crank shaft, B, B, revolving through four plunger boxes or bearings, c, c, c, c, cast on the bed plate, with caps and trusses of metal; and the said shaft drives the wheels keyed thereon. Attached to rams 1 to 4 are screwed metal lugs, 13 to 16, through the centres of which are drilled holes in which pins, 17, traverse, fastening the forked levers, D, d, D, d, which stand vertically

above and below surface of bed plate, to which they are attached by suitable lugs or pins at 17. The vertical levers D, D, D, D, in projecting below the bed plate, are at their fulcrums, a, a, attached to carriages or brackets hanging beneath, and bolted under surface of bedplate. Connecting rods, c, c, are pinned or jointed from a, a, to bell-crank shaped levers d, d, working at e, e, on their centres or stud brackets at e, e, which form pivots, said brackets or carriages being bolted under bed plate. The other end of bell cranks, d, d, are connected by pins at g, g, to forked connecting rods, h, h, the upper ends of which are connected to main (B, B,) and minor shaft (B¹, B¹,) crank shafts by metal butts and straps.

The object of this lever adaptation is that when

No. 1 ram is propelled out from its cylinders it presses, by means of the lug and pin fastened through lever D, upon the said lever, which, being thus driven forward, the lever draws the horizontal connecting rod a, bell-crank lever d, and forked connecting rod h, backwards, the necessary distance to obtain by this movement a half throw of main crank driving shaft B, B, and thus causing a half revolution of said crank shaft. This accomplished ram, No. 2, moves forward instantaneously in like manner, and No. 1 retires. The forward pressure of ram No. 2 drives the lever D, and the lever attachments thereof in like manner to No. 1, and thus causes, by means of its half stroke, the second half revolution of the main shaft, thus completing the revolution. On centre of main shaft is keyed the fly-wheel E, which revolves through a slot in the bed plate performing its revolutions. At base of ram cylinders 1 to 4 are screwed in the plunger cylinders 5 to 8, and on top of the ram cylinders at H are moveable cup reservoirs H, which fit into screw holes drilled in the metal communicating with the interior of the cylinders. These cups are of glass, to allow the charge of water in the cylinders to be gauged, and contain self-acting valves, by which any deficiency may be replaced.

When the cylinders are filled with water, these cups are screwed in and also filled with water; a metal cap is then placed on the head. Pump-plunger cylinders, 5 to 8, consist of hollow cylindrical tubes, and in them, moving through stuffing boxes, work solid metal pump plungers 18. Each series of pump plungers are united by cross heads k, in the centre of which are screwed guide rods l, which work through guides m, bolted to bed plate, and attached to forked connecting rods applied to the minor crank shaft B1 by butts and straps. The revolutions of the minor crank shaft B1 are caused by the working and pressure of the rams 3 and 4, the pressure of these rams being communicated by a similar lever arrangement, as described of rams No. 1 and 2. At each revolution of the B1, upon which is keyed the fly-wheel P, each half throw drives inwards the pump plungers 5 and 6 of rams 1 and 2, and as the pump plungers descend in their cylinders they press forward and eject under the base of the rams 1 and 2 the water which was contained in each, and as this water presses upon the base of the rams by the descending of the pump plungers to the end of their stroke, so in proportion the rams press forwards, upwards, and onwards, conveying the augmentation of hydrostatic power thereby generated upon the levers, causing, as before described, the rotation of the main crank shaft B, B, whereby wheels attached thereto are driven. Parallel with the end of the pump plungers 5 and 6 of the rams 1 and 2, and with a space intervening, are bolted down upon the bed plate the series of pump plunger cylinders 7 and 8, fastened into the base of the rams 3 and 4, also bolted down upon the bed plate. At the cross heads k, k, of the pump plunger cylinders 7 and 8 of the rams 3 and 4, there are screwed on lugs r, slotted out to receive the upper end of forked levers S, which oscillate upon pins at t, placed through the centre of the lugs. The fulcrums of the forked levers work upon studs fastened at the base angle of hanging brackets bolted under bed plate. The upper forked ends of the levers by their pressure forward drive by their alternate action inwards the pump plungers 7, 8, which in their stroke eject from their cylinders the water contained in each under the base of the rams 3 and 4, which press forward in manner as before explained upon the minor crank shaft B1, which again performs its office. The levers S, S, which work in brackets fastened under bed plate, thereby giving pressure upon the cross-heads k, of the pump plungers 7 and 8, are driven backwards and forwards, thus pressing and retiring after delivering each stroke, by the action of two connecting rods running under bed-plate, which are fastened to the levers S, S, and which work horizontally and parallel to each other beneath the bed-plate. At the other end of the connecting rods they are attached to the double throws of an auxiliary crank G. Upon the end of this crank shaft is fastened a V-grooved wheel B3, in which works a gut band connected with an outside foreign power, by means of which the engine is set in motion. On the main crank driving shaft B, B, is keyed a double V-grooved wheel e1, upon the minor crank shaft B1, and upon the auxiliary crank shaft is also keyed single V-grooved wheels, the three V pulley wheels following in vertical line with a gut band passing round each, by means of which is maintained harmonious action, and alternate movement between both systems of rams, and pump plungers, thus also equalising and obviating loss of time between each throw of the respective cranks; and further by this application an equitable upward and

downward movement is given by the working of the engine itself to the pumps, levers, and other portions, without the necessity of regulating the same by hand power. There are other ways and means of utilizing the power acquired, which it is not necessary to describe in connection with the engine illustrated. The engine is set in motion by the rotation of the V-grooved wheel which is attached to the auxiliary double throw crank shaft, which pulls backwards and drives forwards alternately the levers which work by their forked heads in the lugs of the smaller series of pump plungers screwed to the cross heads, thereby pressing by their levers alternately upon the pump plungers which are driven to the end of their cylinders, ejecting as they descend the water from them under the base of the rams, whereby the rams alternately press forward by the intervention of their levers upon the cranks of the minor crank shaft, giving to it half circles, and by the two throws completing the revolution of whole circles, the cranks in those half circle revolutions press alternately upon the guiding rods, lugs, and cross heads of the series of pump plungers attached to the larger series of rams; thus conveying on those pump plungers the entire of the augmented hydrostatic force generated and produced by the pressure of the small series of pump plungers upon the bases of the lesser series of rams before alluded to. This increased force pressing upon the bases of the major series of rams, drives forward upon the levers thereof the whole force, and thereby the cranks of the main driving shaft rotate upon their axes, and by that means communicate the hydrostatic power for the driving wheels and all manner of machinery, and ensuring continuous rotary motion.

ANSWERS TO CORRESPONDENTS.

Our correspondents will observe the pruning knife is often used on their communications: will they kindly spare us the trouble!

J. O.—Will see we have stopped the subject. He will find the matter treated on already. Were we to answer the many inquiries by post, we should have no time for aught else.

JUAN.—The languages are English, French, German, Italian and Spanish. You inquired some time since respecting sugar; if you will send for Spon's new catalogue, you will find something there to interest you.

JOHN THOMAS.—Will endeavour to meet your requirements. JUST IN TIME.—Weale, Lockwood, and Spon's catalogues. Send your address, and request for a catalogue. Thanks for your letter.

DELTA.—Very hard to say how much, but certainly not more than half of the power generated.

GRACIOUS.—The idea is good, but we think a rather roundabout way of increasing the power. Yet in certain situations and conditions, which you evidently are aware of, the gain would be about 35 per cent. Do you think it would pay you to go on? Paper destroyed.

THOMAS WOOD.—You are quite correct. It is an American "claim," and was not noticed by us before sending to printer.

A. B.—Can't give you prices. Chipperfield and Messent, 8, Newgate-street; John Lever, Size-lane, Bucklersbury; Partridge and Cosens, Fleet-street.

ASPIRANT.—The subject you speak of is important, and will receive attention. It has been announced by us among our usual "notices."

ANATHEMA.—Comical, stupid, aggravating error.

J. NEWTON.—Too late; next week.

INVENTOR.—Will give it a thought this, and answer next week.

MAGNETISM.—We were told by a Manchester man the other day, that he and many others took it to get a look at any ideas coming out. This would suit you; but be careful how you go to work. We heartily wish you success; and—let Glasgow flourish.

APPRENTICE MECHANIC.—Only fig 2 come to hand. You send fig 1, we will insert it for you.

W. BATTY.—No room for the matter.

R. C.—The work is we believe in German, and may be obtained through Trubner and Company, booksellers, Paternoster-row.

APPRENTICE.—See our next: lack time this week.

TURBINE.—Your turbine, were there no waste, would consume as near as possible 8.8 cubic feet of water per minute. As perfection of use has never yet been obtained, you would, as the useful effect is not much more than 60 per cent., require a supply of over 13 cubic feet per minute. The horse-power is equal to 500 lbs. falling 66 feet; and to get a horse-power out of your 60 feet fall, 550 lbs. of water must fall per minute. The cubic foot of water weighs 62.5 lbs.

CHAMBERS (Derby).—1, Wine Office-court, Fleet-street; weekly price, fourpence.

JOSEPH SLATER.—Your question has been answered more than once. The invention is claimed by many.

•• We have to ask our correspondents to so sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them by the thousand; the same with "Well-Wisher," &c. If they don't like to see their own names paraded, use those of an ancient or any other man.

Several letters remain over till next week for answer. LETTERS applying for invention to be furnished by post cannot be attended to.

THE ENGLISH MECHANIC!

NEXT WEEK will be published the
FIRST VOLUME

of
THE ENGLISH MECHANIC,
A Record of Mechanical Invention, Scientific, and
Industrial Progress.

UPWARDS OF ONE HUNDRED
ILLUSTRATIONS.

Handsomely bound, gilt edges, 4s. 6d.; post free, 5s.
GEORGE MADDICK, 162, FLEET-STREET, LONDON,
and all Booksellers.

THE ENGLISH MECHANIC.

Every Tuesday, One Penny. Monthly Parts, 5d.

This day (No. 26) completes the First Volume.

*. * Title Page and Index, One Penny. Cases for
binding, One Shilling and Sixpence.

It is solicited that all back Numbers be ordered at
once.

All the early Numbers have been reprinted. It
is therefore necessary that sets be made up at once,
as there will be no further reprints owing to the
great expense they entail.

162, FLEET-STREET, LONDON, and all Booksellers.

TO ADVERTISERS AND CORRESPONDENTS.

*. * In future all Advertisements and Communica-
tions for the Editor to be sent to

162, FLEET-STREET.

OUR MONTHLY PARTS.

Part 5 of THE ENGLISH MECHANIC, in coloured
wrapper, is now ready.

Price 6d. only! Post free, 7d.

All back Nos. have been reprinted, and can be had
direct from our Office, or through any bookseller.

TO ADVERTISERS.

As the ENGLISH MECHANIC addresses itself to the largest
and most intelligent portion of the community, and is
the only Paper of the kind established, it offers unusual
advantages as an advertising medium.

SCALE FOR ADVERTISEMENTS:

	£	s.	d.
Five Lines	0	3	0
Every additional Line (Nine Words) ...	0	0	6
Whole Page	8	8	0
Half Page	4	4	0
One column	3	0	0

Post-Office Orders to be made payable to GEORGE MAD-
DICK, Fleet Street Branch.

All Advertisements should be sent to us not later
than Friday.

The English Mechanic.

FRIDAY, SEPTEMBER 29TH, 1865.

PATENT RIGHT AGAIN.

IT was not to be supposed that the opportunity or
the British Association meeting would be ne-
glected by those anxious to upset Mr. Woodcroft's
and the Commissioners of Patents' vocation—by,
what they have themselves elected to be called, the
Freestalers of the day; and it was known for a
short time previously to the meeting, that Mr.
Rogers, Professor of Political Economy, Oxford, had
braced himself up for the attack on patent rights,
backed by Sir W. Armstrong, and Mr. Vignolles,
C.E. But Oxford generally has been distinguishing
itself of late, in a manner qualified to astonish its
friends and well-wishers. It has done a trifle in
Parliamentary distinction, in the case of Mr. Glad-
stone; and, as the yellow leaf shows by the hedge, it
tones down into advocacy of Freestealing. Mr.
Rogers is, we are told, a representative man—we are
sorry, then, that he has given way to the company
of "appropriators," the more so that we greatly re-
spected him when he wrote so fluently in favour of
copyright—and of course against Freestealing. We
were glad, then, to hail one who, by sheer pluck and
hard endeavour had reached an elevated position;
our grief now is correspondingly lachrymose. It re-
quires a stout heart to face a "stealy brao;" on the
other hand we may quote an old and true saying,
which begins "Facilis descensus."

But, however great and marked may be the fall of
Mr. Rogers, he shall drag no one down with him to
whom we can be of assistance—and act one incl

shall we budge from our original stand point, notwithstanding his windy oration at Birmingham. We maintain that a man has a right to that protection from the law which will enable him to realise a compensation for the labour of his brain—the equivalent to the nation being the use of that brain's progeny; that it is the duty of the parent government to provide this protection; and that what we want now is, not the abolition of the patent laws, but the alteration of them, so as to provide for all the greatest amount of protection and benefit at the lowest possible cost. Birmingham owes its great success as a manufacturing centre to the patent laws, and those who are most concerned in the success of the grimy town freely concede this. Mr. Bessemer, the Great in Steel, has stated, we believe, that had he not seen his way to fortune through the doors of the patent office, his labours would never have been protracted to the extent they have been; and, however great may be the love of his kind in any man, we are sadly afraid that were a person of an inventive turn of mind once satisfied that the fruits of his inventions would go principally to the enriching of capitalists—the barren honour only falling to his share—he would cease to usher into the world the creations of his intellect. It is not a case of free trade *versus* protection—it is one simply of private property.

But we have not space to comment further on the matter. Our business is with Mr. Rogers. He has put himself forward as the Freestalers' Champion—and in this last round has failed to come to time. True, he had Mr. Vignolles as his second; but Sir W. Armstrong, great in guns, and strong in coal predictions, was conspicuous by his absence from the field. Having failed here, it is to be hoped that in the ensuing Parliament the failure may have its weight, and honest men their due. We do not mean to insinuate that the worthy Professor is not honest in his course; he is too much of a gentleman to be aught else; but he has turned coat, and that is a damning argument against him. Let the law be altered—Patience knows they sadly require it; let the fares on the turnpike to—fortune?—be altered; and sufficient will have been done to enable us to go on, inventing and making ourselves a name, for the next fourteen years.

ON THE CAUSE OF THE VIOLENCE OCCASIONALLY ATTENDING THE EXPLOSION OF STEAM-BOILERS.

Few questions of practical science are surrounded with greater mystery than the cause of the violence with which boiler explosions are sometimes accompanied. If a comparative degree of violence was at all times associated with the explosion of boilers, no doubt the cause of the explosion itself could be ascertained. This, however, does not happen to be the case. By far the greater number of boilers are destroyed quietly, and without any greater manifestation of violence than if they were simply burst open by cold hydraulic pressure. This seeming paradox of explosions occurring under the two opposite conditions has involved the whole question of boiler explosion in uncertainty. It is a singular fact that the more dangerous and formidable explosions have been known to have taken place in boilers while at their ordinary working pressures, whereas one would generally be led to consider that, except in cases of undue pressure, or some inherent defect in the construction of the boiler, no explosion could come to pass. The majority of ordinary boiler explosions which occur unattended by any great amount of percussive force or detonation are induced, no doubt, owing to some defect which is unobserved during the construction of the boiler, or which becomes developed while the boiler is in process of working. It is surprising, however, to reflect that at least seven out of every ten boiler explosions which take place are put down to some entirely metaphysical and unexplained cause. Leakage is, of course, a very frequent forerunner of these catastrophes; but the forms under which leakage itself takes place are very numerous. Although few have been investigated with so satisfactory a result as could be wished, they are sufficiently marked to lead to the conclusion that their causes are very different. Vibration of the boiler in its bed, by causing some change in the molecular arrangement of certain parts of the boiler, may often lead to openings along the rivet seams, or in the plate itself, which afterwards become enlarged to full and developed leakages. When the water once finds a flow through the narrowest channel, it begins a scour upon the sides of the opening, tending to widen and increase the flow, and when the air is reached a combination sets in between the metal, and the oxygen contained in the

water forming an oxide which is continually washed away by the force of the escaping water.

The orifice then becomes widened by successive corrosions of the surfaces, while a steady oxidation sets in on all the surrounding parts. The same class of phenomena are also more or less associated with steam leakages occurring above the water line, only that in this case the growth of the leakage would be accelerated, as the abrasion of the escaping steam would operate upon the surfaces of the metal with more force than a leakage of water. This does not take place at first. Owing to the comparative freedom of steam from oxygen, very little decomposition of the surface of the metal would take place unless in the case of a leakage of long duration, as the hydrogen of the steam absorbs the oxygen from the air as soon as it meets with it in the course and direction of its escape. When condensation sets in round the leakage, oxidation commences, and the leakage is consequently rapidly extended. Probably in boiler engineering the various forms of leakage, and more especially those which result from vibration, do not meet with so much attention as they deserve. The familiar noise produced by a kettle may be heard upon a much more extensive scale in the case of a good-sized boiler in which the steam is being got up. In the one case the waves of vibration succeed each other so rapidly that, like the revolution of the prismatic colours on a disc, although they may not be in every respect the same as to duration and force, but a single impression is conveyed, being that of a uniform and prolonged sound. In the case of the boiler these vibrations assume the character of trifling concussions, each of which is perfectly distinguishable from those that precede or follow it, and very frequently these minute and innumerable shocks effect a serious modification in the material of which the boiler is formed.

There is besides a constant circulation, as is commonly known, of the water in all boilers, tending to produce a great amount of vibration. This operates in oblong boilers, causing a current in the direction of their length from the front end to the back, and in other classes of boilers in a direction, of course, varying with their form. The velocity and force of this current differs with the quantity of water contained in the boiler and the intensity of the heat used to effect its conversion into steam.

This is a serious and frequent cause of boiler destruction, for it must be remembered that when a certain heat is attained both in the steam and in the furnace, and corresponding conditions are established between the heat of the boiler itself and the atmosphere that surrounds it, a sort of communication is established between the internal and external atmospheres, and it is owing to the want of a fuller knowledge of the phenomena which transpire at this crisis, probably, that many disastrous cases of boiler explosion may be fairly attributed. In boiler ruptures, caused simply by the expansive force of steam, it would seem as if in some cases gases of which steam is composed possess a force of adhesion, or combine with such strength after they have attained a certain degree of electricity, that they do not operate in an inferior direction, but accumulating their force beyond this pitch they wait until they encounter some more formidable obstacle, and in a moment everything is hurled on to destruction by the fearful violence with which they become disengaged. The proximate cause of boiler explosion is yet involved in great obscurity. It was considered by Dobereiner, that chemical combinations and decompositions could be effected through the medium of the closest textures of iron, or other bodies, by simple capillarity, but the results attending the operation of caloric, light, and acidity are such that human ingenuity can scarcely hope to arrest them, however successfully such results may be provided against. The atmosphere where it comes in contact with the external surfaces of a boiler plays a much more important part than may be held generally to be the case. A boiler well heated and producing a good steam may be compared to a cylindrical body trying to hold all its parts together between two equally balanced forces which tend to separate them, by pressures acting in contrary directions. Whatever may be the subtle nature of the phenomena by the operation of which water becomes converted into steam, it is clear that a reciprocal change is continually going on between the atmospheres inside and outside the boiler. Besides its effective work in giving motion to the piston of an engine, steam operates very powerfully in another direction. The entire movements of an engine are due to the momentary diversion of steam force, from the more natural way in which it would seek to expand or set itself free. This it is always attempting to do except at the intervals when its force relaxes under a momentary but abnormal liberation into the cylinder. The true

direction of steam is away from work. It has been found by recent experiment, that there is no class of metal so compact or homogeneous as to be altogether free from percolation, or the molecular structure of which would separate it from those that are known to be porous. Carburetted hydrogen passing through an ordinary iron gas pipe, although having a force of direction given to it, may be adduced as an illustration. Before the gas reaches the extremity of the tube not only will the hydrogen have exuded between the molecules of the tube, but other and entirely different gases will have entered and assumed its place. Thus, unless there is always a strong flowing current of gas, an explosion in exposed gas mains would be always imminent when a flame was brought near any opening made in them during the time of their being tapped, or bored for connections. When the current of gas flowing through them is strong the danger is diminished.

It has been stated by some writers on boiler engineering that a continual change of pressure is taking place in the boiler, owing to the variation of the load put upon the engine, and that very little difference arises regarding the working of the boiler itself when once the steam is fairly up.

Morosi was of opinion that on the stoppage of the piston at each end of its stroke, the whole force of the steam was so violently arrested as to cause it to strike back suddenly into the boiler, and burst it open. Now, it is obvious that wherever a force operates upon a fixed and immovable body, it reacts upon itself; and this must be, in a certain measure, the case with steam issuing from a boiler. But the causes which lead to variable pressures in the force of the steam are much more numerous at the seat where the steam is generated than those resulting from a difference in the working load of the engine. The phenomena of steam generation has been, perhaps, too much overlooked in regard to boiler explosion. The leakages of steam are not so numerous as the leakages of water in boilers; or where water is the resisting body, and steam the force, the force will operate by preference. It will not yield or escape unless it be impossible for the water to escape, and, in this case, the resistant then becomes the force. A thermometer inserted in water passes through certain localities in which heat has taken up a situation, until it assumes the form of a globe, and ascends. It is known that these localities cannot be spherical. The chief difference between fluid and solid bodies is that the former are more or less spheroidal, while the latter are more or less crystalline. The points of contact between three circles would enclose a space which, when reversed, would form a circle, and it is so with globes. Their points of contact are so arranged that the spaces left within them would constitute other globes of the boundaries of these spaces where placed in convexity instead of being concave. Thus convexity and concavity is to the material what life and death is to the moral world. It is manifest that such must be the order of the aggregation of water that this spheroidal condition is presented, and that heat enters and converts the spaces into globes within which it remains and ascends. There is no other situation in water that heat could occupy, for if any combination took place, there would be no useful effect, no violent ebullition. Water would no longer conduct heat vertically any better than it does longitudinally, and it is only when heat passes up through the water into what is called the steam space that the true action of heat on the water commences. The condensation of the air in the steam space then becomes so accelerated, that at last it reaches an intensity that will not admit of its being safely confined. F. M.

(To be continued.)

MANUFACTORY OF LUBRICATING OILS.—The firm of Morehouse, Merriam and Co., of Cleveland, Ohio, manufacturers of compound lubricating oils, now turn out from their factory from four to five thousand gallons a day, and have capacity, if pressed with orders, to produce double that amount. They give employment to about fifty hands.

FRENCH AND ENGLISH MANUFACTURERS.—The *Courrier au Bas Rhin* has the following paragraph:—"We learn a new victory of the construction of French machines over the English, and this time it is in Alsace that the machines will be constructed. The Baden Government lately invited tenders for 46 railway locomotives. The English offered to build them for 70,720*l.* apiece; some Baden manufacturers asked 55,720*l.*; finally, the Gaffensstaden (French) works asked only 45,000*l.* This last competitor had its tender accepted for 22 locomotives; the 24 others were adjudged to the Badeners, and the English got nothing, on account of their price being so high."

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents.]

[With the letters on the subject that appear in this week's number closes the correspondence on Electricity, and the matters growing out of it; more space we cannot afford. Many correspondents have not been noticed, as their requirements had been treated of in previous numbers, and numerous letters have been denied admission, they being, in many cases, repetitions. We cannot help venturing the expression that in no other instance has there been so great an interest shown on any single subject as on this. To the various contributors we tender our own and the thanks of all our readers for their kindness and hearty co-operation; and, in the next subject of importance put forward for discussion, we hope to have as copious and energetic support. The more brief the communication—consistent with value—the better chance will it have of insertion. We would suggest the matter of working tools, in any profession, as a fit matter for discussion.]

MAGNETO-ELECTRIC MACHINE.

Sir,—Further particulars being required relative to the construction of magneto machines, in addition to the rough outline already given by me, I beg to hand you a sketch of one:—

M is a compound steel magnet 10" high x 2" x 2½" in breadth, fastened to a standard of wood, E, E, the revolving horse-shoe electro-magnet fitted on spindle B. The wheel W is connected by an endless string to a groove on the spindle; on turning which, a very rapid rotatory motion is communicated to F, F.

At each revolution four distinct currents are set up, viz., two on approaching, and two on receding from, the poles of steel magnet; the former being comparatively weak, are destroyed, and the two latter caused to flow in one direction. To effect this a commutator is used, consisting of a cylinder of wood, A, on which are fastened two insulated strips of brass, a', a'', arranged opposite each other, with upright springs s', s'' alternately resting against the brass and insulated portions. The ends of wires c', c'', are fastened to these brass strips.

C is a sectional view of a commutator so made.

When the revolving electro-magnet approaches the poles of steel magnet, the upright springs press against the wood, or insulated portions of cylinder, thus preventing from passing, and rendering useless the currents set up. On it receding from them, the upright springs are brought in contact with the metal portions of cylinder, allowing the currents to pass out of insulator.

To any one acquainted with magnetism it must be apparent that the current set up in the coils of revolving magnet, when proceeding in a direction away from N-S of steel magnet must be reverse to those generated on its leaving S-N, on account of opposite polarity; but this cannot affect the direction of the current in any part of the circuit beyond the instrument, because every change of position on the part of the electro-magnet necessitates a proportionate change in the position of commutator, or current reverser; for instance, if the helices be wound in a right-handed direction, commencing at c', on the electro-magnet receding from N-S, c' will possess the properties of a positive pole, and c'' that of a negative pole of a battery, and as a', a'' rest respectively against s', s'', the currents passing out by these springs assume the same properties. When, however, the electro-magnet recedes from S-N of steel magnet, the current at c' will resemble a negative, and at c' a positive pole; but since a', a'', now rest respectively against s', s'', the currents passing out by the springs to the terminals T, T, are of the same name, as in previous case.

The current produced by magneto machines, although

intermittent, have all the appearances and properties of a continuous current, owing to the great rapidity with which they may be caused to follow each other.

Such an instrument as I have here described will answer the requirements of your correspondent "Magneto-Electric Machine."

If the revolving magnet be coiled with several thousand turns of very fine wire (No. 49), the results obtained will be analogous to the high tension currents of a Ruhmkorff coil.

If it be coiled with about 50 or 60 yards of stout wire (No. 12), currents of great quantity are obtained, capable of fusing short lengths of fine wire, or if passed through charcoal points of producing a small electric light.

ELECTROTYPING BY MAGNETISM.—For electrotyping I should recommend "Henry Watson" to coil the magnet with about 50 yards of No. 24 copper wire; but a smaller apparatus will perhaps suit his purpose equally well if his operations are on a small scale.

The instrument must be joined to the decomposing trough in same way as with a voltaic battery: the article to be electrotyped must be joined to the terminal resembling the negative pole, and the plate of metal to the positive pole. Both the plate and article to be electrotyped must be immersed in the decomposing bath.

It may happen, through an error in coiling, that the current passing out by the terminals T, T', will become reversed; it will therefore be an advantage to be able to distinguish the positive from the negative pole; this may be easily done thus:—Connect a bright wire from each of the terminals, and place the two ends in a glass of water near each other, but not in actual contact. On putting the instrument in operation, one of the wires will become oxidised; this will be the positive pole, the other the

negative. Or if a galvanometer be at hand, the two wires can be joined in circuit with it, and the direction of the deflection noted. Compare this deflection with that shown on it by a voltaic battery.

EDWIN FURZE.

ELECTRICITY, &c.

In reply to W. S. S., he will find "Russian Glue" suit his purpose for applying emery to glaziers. "Magneto-electric" will find his question answered by Mr. E. Furze in No. 23, and I quite agree with that gentleman that the commutator is a hopeless case with a mere verbal description; it must be seen to be understood.

I should strongly recommend Mr. H. Watson to construct about six cells of Daniell's battery, small ones will do, and then he will have a cheap, efficient, and lasting means of electro-plating, for which purpose the magneto-electric machine is not adapted, nor do I think it can be as a commercial success, and I think few amateurs would like the constant imitation of organ grinding it would entail upon those who wished to employ it experimentally.

In reply to "Steam O" some few years ago, Mr. W. Fairbairn, of Manchester, conducted a very elaborate series of experiments upon internal and external pressures upon tubes, using glass as being the most homogeneous material at his command. As the result of these experiments I think he somewhat startled the engineering world by stating that a tube would bear seven times the pressure internally that it would externally—hence "Steam O" will perceive that in order that his boiler should resist the atmospheric pressure when a vacuum is formed inside, it should be made strong enough to bear 105lbs per square inch steam pressure.

"Amalgam" must dissolve sealing-wax in methylated spirit, or, which is better, if easily procurable, in naphtha. This is done more readily by pounding the sealing wax in a mortar before adding the spirit and applying a gentle heat while the wax is dissolving. Make it about the consistency of ordinary paint and apply it with a brush; it will soon harden.

"Felix" has been "happy" enough to find a different solution to the "cistern question," from that given by C. T. Whitwell, and myself, and W. Bradbury agrees with him. I thought the object was to find a correct solution, not one that should differ from another. If mine is wrong I pray you, "Felix," show me where; but the propounder has not

yet stepped forward to say why his cistern leaks by night, and not by day, and that is a matter of greater import than even the solution of the question itself, for upon it rests the momentous question as to whether the cistern could ever be filled.

As I never happened to have a work on electricity in my possession save a few numbers of the "Electrician," I most willingly bow to the correction made by Mr. E. Furze in the ratio of resistance between iron and copper, since "Bequerel" is an authority in the science; this admission will, however, affect the conclusions I have arrived at and placed before your readers, not in their substantive accuracy, but simply in the amount to which they extend.

There is a paragraph in your No. 24, page 285, which I think requires a little light thrown upon it. The subject is "Experiments with the Magnesium Light." Great credit is bestowed upon Capt. Bamber, R.N., the whole of which he is no doubt entitled to receive, but the paragraph says "The burner is enclosed by a powerful lens or bull's eye glass which has the effect of not only magnifying the light, but of materially intensifying its rays." Is this true? or is it a "lapsus penae" of your correspondent who witnessed the astonishing phenomenon? That a lens will concentrate the rays of light is an optical law, but I am sorry at a loss to understand what combination of certain molecules of glass should succeed in not only magnifying but actually intensifying the rays of light transmitted by them.

WM. TONKES.

[Mr. T. will observe we have given place to another correspondent as to part of his answer. Reason—first up in type. The "lapsus" referred to was inserted unwittingly: an oversight.—Ed. E.M.]

Sir,—A Goldsmith (No. 23), apparently confounds an induction coil, with a magneto machine—under such circumstances, it would have been a matter of surprise had he met with success in coiling both helices continuously in one direction. If the instructions given by "Electra" and "W. Tonkes" had been followed out, I feel certain no difficulty would have occurred.

E. FURZE.

Sir,—In answer to a "Young Mechanic," in No. 24, the small electric machine described by "R. Booth" No. 15, will answer for giving shocks; but, like all other friction electric machines, it must be in conjunction with the Leyden jar.

2. He can obtain a glass cylinder as described at the electrician's or optician's shop.

3. Any metal wire will do for the points of the conductor; but mine are made of brass.

4. The number of wire points are not particular—say four or five for a machine that size.

5. Common tin will do as well as tinfoil for the conductor; but the edges, when the tin is joined, and also the ends of the conductor, must be filed smooth, or the electricity will escape from any point or asperity.

6. The wire points must be fastened on the conductor by solder, or otherwise to within a short distance of the glass cylinder—say quarter inch.

7. The following is a recipe for the cements to fasten the glass rod to the conductor: 5 lbs. resin, 1 lb. each of bee's wax and red ochre, and 4 oz. of plaster of Paris. These should be melted together till the frothing ceases, and the composition runs smoothly.

8. The wire at the end of the conductor with the knob to it can be of any length; but 3 or 4 inches would be likelier than 3 or 4 yards.

9. Any kind of paint will do to paint the machine with, or it will do without painting.

"Amalgam" can cover the ends of an electric machine with sealing-wax by dissolving the sealing-wax with a gentle heat in spirits of wine, and applying it in the same manner as paint with a brush.

J. WATSON.

We add the following extracted from an answer almost similar to the above:—

"(9.) The wood-work is best if French polished. The ends of the machine may be varnished. Make your varnish thus:—Break up some sealing-wax into small pieces and place them in a phial; pour on them either alcohol or wood naphtha. Keep it well corked, or the spirit will evaporate. Apply it to your work with a small brush.

If "Mechanic" wants more information, address a letter to

J. BACON.

Madeley-street, Rose-hill, Derby.

Sir,—For calculating the natural sines of angles:—If "Fentonian" wishes to investigate the subject, he will obtain much valuable information from Hutton's Course of Mathematics—article "Analytical Plane Trigonometry." If he only requires the natural sines for any mathematical process, then purchase "Chamber's Education Course," price 3s. 6d. Or, if he has a table of logarithmic sines in his possession, the "natural" can easily be deduced from them by deducting ten from the index of the former. This gives a logarithm the number corresponding, to which is the natural sine required.

In reply to his second query, the square of the chord of any arc is equal to twice the rectangle under the radius and the versed sine.

"Induction Coil" can use gutta-percha-covered wires for his primary, provided the covering is very thin, since the tension is not very high; but if the wire is thickly coated, it will make the coil cumbrous, and remove the secondary too far from the central core. With regard to the use of the condenser, I do not think it could be more clearly laid down than by the editor of the "Electrician." In the first of a series of papers upon the subject (Vol. 1, p. 184) he says:—"The intensity of the inductive effects in the secondary wire, or the rapidity with which the electricity accumulated in this conductor, is liberated in a static form, is obviously dependent upon the instantaneous character of the inducing causes in the primary wire. The prolongation of the battery current by a current of induction in the same direction diminishes, therefore, the effects of induc-

tion in the secondary wire when battery contact is broken. When a magneto-electric effect is produced by the insertion of a fasciculus into the axis of the coil, the induced current in the primary as well as in the secondary, is augmented. The importance of the condenser which accumulates on one of its coatings the electricity of the induced current, which otherwise would traverse the primary wire, may thus be appreciated."

"A. Crofts" will find rather an improvement than otherwise, so far as the intensity of current is concerned, by the alteration he refers to; but his outer vessel must be either porcelain or common brown ware, a cylinder of sheet zinc being used, sufficiently large in diameter to leave $\frac{1}{2}$ " all round the porous cell. The copper only need be a flat

strip, bent thus  the part a forming a shelf for the

crystals of sulphate; a little more care is, however, required in this arrangement, as endosmosis takes place more rapidly, and the porous cell is apt to become too full and overflow into the outer cell, ruining the zincs. As I stated in a previous letter, these two "Moesses" are the greatest sources of evil in all battery arrangements where porous cells are used, save in the "Marie Davy." The best cells I have found yet in overcoming this evil are those made at the Imperial Poteries, Lambeth. A Daniell's battery coupled for intensity, and using acid, will not keep in good action for much more than a week with any arrangement.

W. TONKES.

[No room this week for remainder.]

FLOATING BODIES.

Sir,—With regard to "Novice's" illustration of the board and bullets, I have only to say that as bullets are neither a fluid nor a liquid, the board will not float.

An inflated balloon presents three peculiar features, viz., the great care taken to prevent its untimely departure by being strongly tackled to the ground; the rapidity with which it darts from the ground, as if impatient to get away from the habitations of man; and, though last, yet not least, the higher it gets the slower is its upward progress.

In looking for a cause through which the foregoing effects may result from, I find two forces continually in operation, viz.—the force of gravity and centrifugal force, which latter force results from the earth's rotation on its axis, and which I to believe is the cause of bodies floating.

While considering the floating of a balloon, centrifugal force may be objected to, seeing the machine is away from the surface of the earth; but it must be borne in mind, our very atmosphere is obedient to the law of gravity, and is carried along with our planet round the sun in its orbit, and so long as the machine remains within it, it will be under the action of these two forces.

Viewing it then in this manner, I can account for the cause of its being strongly tackled to the ground; and, as centrifugal force is strongest at the surface of the earth, I can see the reason why its upward speed is at its greatest. Immediately on its being liberated, that speed will gradually decrease until a point is reached, where centrifugal force and gravity balance each other, it will then float in equilibrium, which can only be disturbed again by reducing the quantity of matter contained in the machine, when the preponderance will again be in favour of centrifugal force, thereby enabling it to rise to a greater height.

Before concluding my letter, I may mention that a former correspondent spoke of specific gravity combined with the pressure of water or air as the cause of bodies floating; but specific gravity is not a force. I consider it merely as a preparatory step to allow centrifugal force to make a visible effect.

WM. AIMER.

[This matter must now be considered closed.]

THE MANUFACTURE OF CAST STEEL.

By H. BESSEMER, ESQ.*

The paper opened with a review of the inventions which had finally resulted in the establishment of "Bessemer" Ironworks throughout the country. It pointed out at some length how the disadvantage of the old fixed converting vessel was remedied, and other improvements introduced. Up to this period the manufacture of cast steel by the old as well as the new process was still so far imperfect that steel of the highest quality could not be made from inferior iron. In 1839 the trade of Sheffield received an enormous impulse from the invention of Josiah Heath, who patented in this country the employment of metallic manganese, or, as he called it, "carburet of manganese." The addition of a small quantity of this metal, say from $\frac{1}{2}$ to 1 per cent., rendered the inferior coke-made irons of this country available for making cast steel. It removed from these inferior qualities of iron their red shortness, and conferred on the cast steel so made the property of welding and working soundly under the hammer. Mr. Heath supposing himself secure in his patent, told his licensees that if they put oxide of manganese and cold tar or other carbonaceous matter into their crucible along with the blister steel it would do as well and be much cheaper than the carburet of manganese he was selling them; in effect, it was the same thing, for before the steel was melted the carbon present reduced the oxide of manganese to the metallic state, so that the patent carburet of manganese was formed in the crucible in readiness to unite with the steel as soon as it became perfectly fused. But the law decided that this was not Heath's patent, and so the good people of Sheffield, after

many years of litigation, were allowed to use it without remuneration to the inventor. Manganese had now been used for many years in every cast-steel works in Europe. It mattered not how cast-steel was made, since manganese added to it necessarily produced the same beneficial changes. No one appreciated the fact better than the unfortunate Mr. Heath, as evidenced by his patent of 1839, in which he declared his invention consisted in the use of "carburet of manganese, in any process whereby iron is converted into cast-steel." Had Heath seen in his own day the Bessemer process in operation he could not have said more. With this patent of Heath's expired, and become public property, coupled with the universal addition of manganese and carbon to cast-steel, it would naturally be supposed that the author, in common with the rest of mankind, would have been allowed to share the benefit which Heath's invention had conferred on the whole community; but it was not so. The reading of the author's paper on the subject, at Cheltenham, in 1856, led to great expectation as to the value of the new process, and licences to manufacture malleable iron, under the patent, were purchased by ironmasters, to the extent of £25,000, in less than twenty-five days from the reading of the Cheltenham paper. Great excitement existed at the moment in the iron trade, and many persons seem to covet a share in an invention that promised so much. There was consequently a general rush to the Patent Office. Some of the gentlemen who applied even repented some of the writer's own patents, while others patented things in daily use, in order that they might be considered new, when added to the products of the new process. The paper described the features of the numerous patents applied for within six weeks of the reading of the paper at Cheltenham, and remarked that if that long series of patents could have been sustained in law it would have been utterly impossible for the author to have employed manganese with steel made by his process, although it was considered by the trade to be impossible to make steel from coke made iron without it. Soon after the reading of the Cheltenham paper several rough trials of the Bessemer process were made privately, by persons in the iron trade, and defects discovered which were supposed by practical men to be perfectly fatal to the invention. The press then spoke of the utter impracticability of the process, and of regrets that the high expectations originally formed were so fallacious; but the storm gradually subsided, and the process and its author were soon entirely forgotten. Imperfections in the process there certainly were, but the author had had the most irrefragable proof of the correctness of the theory on which his invention was based, and also that the reasoning on which it was so utterly condemned by the trade was in itself wholly fallacious. He therefore decided not to argue the question against a hundred pens, but to energetically prosecute his experiments, and to remain silent until he could bring the process to a commercial success. When at the expiration of three years of incessant labour on the part of himself and his partner, Mr. Longsdon, and an expenditure of more than £10,000, the process was again brought before the public, not the slightest interest was manifested by the trade. This was discouraging, and one of two things became imperative; either the invention must be abandoned, or the writer must become a steel manufacturer. The latter alternative was unhesitatingly accepted, and Messrs. Henry Bessemer and Co. determined to erect a steel works at Sheffield, in the very heart of the stronghold of steel making. At these works the process had ever since been successfully carried on; it had become a school where dozens of practical steel makers received their first lessons in the new art, and was the germ from which the process had spread into every state in Europe, as well as to India and America. By the time the new works at Sheffield had got into practical operation the invention had sunk so low in the public estimation, that it was not thought worth paying the £50 due at the expiration of three years on Mr. Mushet's large batch of manganese patents. They were consequently allowed to lapse, and become public property. The author had therefore used without scruple any of the numerous patents for manganese without feeling an overwhelming sense of obligation to the patentee. At the suggestion of the author, works for the production of manganese and alloy were erected by Mr. Henderson, at Glasgow, who now made a very pure alloy of iron and manganese, containing from 25 to 30 per cent. of the latter metal, and possessing many advantages over Spiegel Eisen, which it would doubtless replace. Specimens of iron manufactured by this process and afterwards bent and tested in every way, were exhibited on a table in the room. The paper proceeded to notice some of the more important applications of

steel as a substitute for wrought iron. In no case, it was pointed out, was this change of material more important than in the construction of ships, for in no instance were strength and lightness more essential. Bessemer cast-steel ship plates were then described, and their advantages illustrated by facts and statistics. The advantages had not escaped the attention of Mr. Reid, the talented constructor of the navy, and they should doubtless soon have substantial proof of what might be effected by the employment of steel in the construction of ships of iron. The application of steel to projectiles was next considered. Next its uses for railway purposes, such as the manufacture of engine cranks, axles, tires of wheels, and even rails. The paper described successful experiments which had been made in the use of cast steel for these purposes. The paper concluded by stating that cast steel was now being used as a substitute for iron to a great and rapidly increasing extent. There were now seventeen extensive Bessemer steel works in Great Britain. There were at present erected and in course of erection in England no less than sixty converting vessels, each capable of producing from three to ten tons at a single charge. When in regular operation these vessels were capable of producing fully 6,000 tons of steel weekly, or equal to fifteen times the entire production of cast steel in Great Britain before the introduction of the Bessemer process. The average selling price of this steel is at least £20 per ton below the average price at which cast steel was sold at the period mentioned. With the present means of production, therefore, a saving of no less than £5,240,000 per annum might be effected in Great Britain alone, even in the present infant state of the steel manufacture.

VALUABLE RECIPES.*

BREWERS' PITCH.—The following compound is recommended as a good and cheap substitute for brewers' pitch:—Coat twice the inside of a barrel with a solution of one-half pound of rosin, two ounces of shellac, two pounds of turpentine, and half an ounce of yellow wax in one quart of strong alcohol. After the complete drying of the second coat, give a last coat by applying a solution of one pound of shellac in one quart of strong alcohol. This varnish will perfectly cover up the pores, and does not crack off or impart a foreign taste to the beer.

TO COLOUR STRAW BLACK.—The following is given to us as a black colour for straw hats. The quantities of material are intended for twenty-five hats or bonnets. They are kept for two hours in a boiling decoction of 4 lbs. of log wood, 1 lb of sumach, and of 5 oz. of fustic; afterwards they are dipped into a solution of nitrate of iron of 4 degrees Baume, then well rinsed with water, and when dry, are painted over with a solution of gum or dextrine. The iron liquor, as well as the other ingredients, are kept by all dealers in dye-stuffs.

A GOOD CEMENT.—An excellent cement for uniting articles of wood with metals, glass, stone, &c., may be obtained by dissolving glue in boiling water and making it of the same consistence as that of cabinet maker's glue; then add, while stirring, a sufficient quantity of wood ashes as to produce a varnish-like mixture. While hot, the surfaces to be united must be covered or coated with this glue compound, and pressed together. When cold the surfaces will be found firmly united, and much force will be needed to separate them again.

VEHICLE FOR COLOUR.—By boiling shellac and borax in water you will obtain a solution of the lac, which may be used as a varnish or as a vehicle for colours; mixed with lamp black, it has been used as an ink that will resist acids.

CHEMICAL CEMENT.—A good cement for chemical and electrical apparatus may be prepared by mixing five pounds of resin, one pound of wax, one pound of red ochre, and two ounces of plaster of paris, and melting the whole with moderate heat.—*American Chemist and Druggist.*

SCIENCE MINUTE.—Several large and influential meetings have recently been held at Belfast, Derry, Dundalk, Coleraine, and other towns in the North of Ireland, for the purpose of organising classes for drawing and science in connection with the department at Kensington. The meetings are reported as very successful.

THE PRESTON INDUSTRIAL EXHIBITION.—This exhibition was opened last week with much ceremony. The Earl of Derby was to have delivered the inaugural address, but his lordship has had an attack of gout, and could not be present. The proceedings were thus robbed of their chief attraction.

* From a paper read to the British Association, 1865.

* From the *Scientific American*.

IMPROVEMENTS IN OBTAINING HYDRAULIC MOTIVE POWER.*

This, the invention of William Thomas Cheetham, of Ashton-under-Lyne, consists in employing a wheel with vanes thereon surrounded by an annular chamber furnished with orifices which direct the water upon the vanes, but the water after it has reached the vanes does not, as in the case of an ordinary turbine, pass onward to the centre or outward to the circumference according as the guide floats are within or without the revolving part, but returns in a direction nearly parallel to that in which it was delivered, and escapes between the annular chamber and revolving wheel.

Fig. 1 represents in vertical section one arrangement by which the principle of the invention may be carried into effect, and fig. 2 is a plan view, one half thereof being in section. A is a revolving shaft through which the power is to be transmitted; upon this is mounted a wheel B, the circumference of which is grooved out, as seen in fig. 1. The annular groove thus formed is provided with partitions C, constituting vanes, but these partitions are not in this instance radial lines, but are of a curved form, as seen in fig. 2, and the two views taken together show, therefore, that a series of recesses D, are formed with curved sides in each direction, constituting cup-formed chambers. Around the wheel B, is placed a water chamber F, the inward circumference of which has an annular chamber divided into compartments by stationary vanes G, similar to guide floats of ordinary turbines, and from the inward ends on each side of these guide floats the water chamber F, recedes at an angle, as seen at F, in fig. 1. The water from the source of supply enters by a pipe H, and fills the annular chamber F; and thence it passes between the guide floats G, which direct it to the circumference of the wheel B, projecting it upon the vanes C, formed thereon. Arriving in contact with these, it drives forward the wheel B, but as a reactionary force takes place, it passes along the doubly-inclined sides which constitute the vanes C, and escapes upward and downward between the wheel B, and annular casing F, as seen by the arrows in fig. 1,—the tapered form of the inward circumference of the chamber F, allowing space for its free escape.

The above description explains the peculiar feature of the invention, but it is capable of modifications, as shown in section at fig. 3. The wheel B, constructed as before described, is mounted over the annular chamber F, which delivers the water to the cup-formed vanes C, through the medium of the guide floats at G; the plan view of this arrangement would show the floats C, and guide floats G, curved precisely as in figs. 1 and 2. In fig. 4 the revolving wheel B, is placed on the outside of the stationary annular chamber F, and guide floats G, which receive their supply of water from a pipe H, leading into a chamber K. In order to regulate the quantity of water which shall be allowed to act upon the revolving wheel, and therefore to govern the power, the spaces between the guide floats may be partially closed by a sliding ring as is practised in turbines, or there may be a separate slide for each space or for any series of such spaces. In fig. 1 is shown the application of one slide at L, capable of being raised or lowered at pleasure.

The patentee claims "the use of a revolving wheel fed by an annular chamber furnished with guide floats, the former being so formed as to return the water somewhat in the direction in which it was delivered. Also the tapered form F, of the chamber which delivers the water to the wheel, whereby the said water is enabled to escape freely."

MAGNESIAN PIPES.—Meerschum is made on a large scale in New York, says the *Boston Advertiser*, by saturating carbonate of magnesia in silicate of soda or soluble glass—care in selecting a good quality of magnesia being the only requisite for success. The profits are immense, as will be seen. Magnesia costs about twenty-five cents per pound; silicate of soda even less. A pipe made of the "foam of the sea," as smokers verily believe, cost for material about five cents, leaving the balance for labour.

RECENT AMERICAN PATENTS.

PACKING FOR WELL TUBES.—The object of this invention is to produce a packing for oil and other deep wells which may be applied when the tube is in the well, and be removed without disturbing the tube. It consists, in general terms, of an upper and lower head, each consisting of an annular plate of metal, between which are placed annular plates or rings of leather, felt, rubber, gutta-percha, or other elastic or flexible material, which rings are connected to each other along both their inner and outer edges in alternation—the first and last of the series being also connected to the said metallic rings. By drawing out the apparatus lengthwise, the rings are drawn asunder, their faces lying in angular directions with respect to each other; and their outer and inner circumferences being drawn toward each other in proportion to the greatness of the angle made between adjacent rings. By letting the rings come together, their inner and outer circumferences resume their former positions, when they will touch the sides of the well tube and of the well respectively. P. Sicouret, of Saragossa, Spain, now at No. 152, Eighth-avenue, New York, is the inventor.

CHEETHAM'S MOTIVE POWER

REMOVING BUILDINGS.—This is an ingenious apparatus by which dwellings and other structures may be readily moved up and down hill, or over uneven surfaces, without straining or injuring the plastering, and without the trouble of levelling the track. J. S. McIntire, No. 68, Cass-street, Chicago, Ill., is the inventor.

SHUTTER HINGE.—This invention provides a means for keeping blinds, shutters, and doors locked, when in an open position, by the movement of the hinge itself, without the necessity of using a separate and distinct device therefor; and this is effected by a very simple and durable arrangement of a small swinging bar or bolt attached to one leaf of the hinge, so arranged that when the shutter is thrown open the bar or bolt falls into a slot and between two contiguous projections upon the lower edge of each leaf of the hinge. The blind or shutter, when open, is held so securely and without any great strain upon the hinge that no ordinary gale of wind can injure it, and, at the same time, the attachment is so simple, and the movement so easy, that a child can close the blind or shutter without any perceptible effort. Its durability and simplicity of action, combined with the fact that it can be made at a mere trifling additional cost above the present price of shutter hinges, recommend it to the consideration of manufacturers. Samuel R. Dummer, of No. 137, Broadway, New York, is the inventor.

ROSE ENGINE.—This invention relates to certain improvements in rose engines intended for cutting glass, and it consists in the use of a parallelogram, the sides of which are hinged together, in combina-

tion with a box calculated to hold a fork or other equivalent device that forms the bearing for the shaft of the revolving tool, in such a manner that said tool can be readily held up to or taken off from the work without danger of causing jerks or jars which would have a tendency to break or injure the work. The invention consists, further, in the application of a hinged tool-holder, in combination with a carriage or slide moving back and forward in a suitable rest, in such a manner that by means of the rest the tooth can be adjusted to any desired position in the usual manner, and by the hinged holder can be brought up to or removed from the surface of the work with the greatest ease and facility, and without danger of spoiling the work. It consists, finally, in securing the shaft of the revolving tool in a forked or other bracket, which is connected to the rest or supports by a set screw or other suitable means, in such a manner that said tool can be readily turned in either direction or detached from the supporter and replaced by another of the same or of different shape. Anton Schwittler, No. 177, Broadway, New York, is the inventor.

SORGHUM EVAPORATOR.—This invention relates to a new and improved pan for evaporating sugar, designed chiefly for evaporating sorghum, and it consists in the employment or use of movable partitions, with an open end pan, and also a side chimney for the furnace, whereby a superior article of syrup is obtained, and the evaporating process rendered continuous it not being necessary to stop in order to cleanse the pan and remove the latter from the furnace, as is now required. Joel Kindley, Oskaloosa, Iowa, is the inventor.

A FRENCHMAN ON WATER POWER.

An ingenious Frenchman, one M. Cazal, has hit upon a plan by which to utilize the force of falling water, not only upon the spot, but at great distances. This gentleman proposes to convert the mechanical force of falling water into electricity. For this purpose he has simply to make the water act upon the wheel-work—just as in the case of a water-mill, only instead of turning the stones which grind the corn the mechanism will act upon a magneto-electric apparatus. The electricity thus developed will then be conveyed to any required distance by means of insulated wires. Just as an operator in London can ring a bell at York, or fire a cannon at Edinburgh, or make a ball descend at Portsmouth, so M. Cazal can transmit the force of a cascade from the mountains of Switzerland to the workshops of Paris. Arrived at its destination, the electric force has simply to be re-converted into its mechanical state, and it does the work as nearly as if the falling water were itself brought to the scene of operation. That at least is the theory, and the theory is true;

we believe it has already been tested, and the French manufacturers are about to try it on a still larger scale than before, though we do not mean to say that M. Cazal has yet gone so far as from Paris to the Alps in search of his power. It is a strange idea, that of seeking in the flood what we have hitherto found in the fire—relying, in fact, on cold water instead of steam. The economy of the process is said to be quite as remarkable as its physical character. M. Cazal, in some sort, finds his power already provided; he merely has to pack it up in a convenient form for travelling, and then to unpack it at the journey's end. At this rate we only want a submarine wire of sufficient capacity, and England might draw its motive power from the mountainous regions of the Continent—the Manchester spindles rotating in virtue of a foreign influence. Or, to stretch the point still further, let us imagine the Atlantic telegraph an accomplished fact, we have then only to send M. Cazal off with a wire to the Horseshoe Falls, and all the force of Niagara itself will be at our command.—*Morning Paper.*

WATER heated in a strong closed vessel has melted lead at 612 deg.

SEA water is both salt and bitter at the surface, but only salt in its depth.

READING INDUSTRIAL EXHIBITION.—The exhibition of industrial productions and valuable works of art lent by her Majesty and the principal gentry of Berkshire, is now open daily at the Town Hall, Reading, and is attracting a constant stream of visitors.

* From *Newton's Journal of Arts*

ON ALLOYS

Every thoughtful metal worker, who has his hands too full of his daily employment to spend much time in experimenting on the properties of the metals he uses, must have often wondered how it came to pass that, with all our boasted knowledge of chemical and metallurgical subjects, we have as yet only succeeded in inventing some half-dozen useful alloys. Brass, pewter, gun-metal, German silver, and type metal are really all the alloys that we can name as entering into the manufacture of the more common articles of trade in this country. The causes of this apathy in experimenting on the properties of mixed metals are manifold. The practical metal worker of the present day is generally ignorant of the chemistry of the metals he uses; and, even if he were well informed, he would be too busy fighting the great battle of competition to set himself the extra task of experimenting upon alloys. But metal workers will turn round, very naturally, and ask how it is that practical chemists, whose business is to make experiments, do not investigate the capabilities of metallic mixtures more frequently than is at present the case? We fear very much that the only answer to be given to this is that scientific chemists of all countries have, almost without exception, been bitten with the mania for nearly exclusively pursuing their researches and expending their talents upon organic compound. This department of scientific chemistry is so vast and so fruitful in results, that it is quite a rarity to see an article in a scientific journal upon a metal or metallic compounds. Even those chemists who have not wholly given up the study of inorganic compounds seem to apply themselves to analytical observations, or to the investigation of the rarer metals. As an example of the want of knowledge of the capabilities of alloys, we may instance the discovery lately made by M. Pelouze, of the French Mint, that the best metal with which to alloy silver is zinc, and not copper, as we have always believed. Now, considering that silver has been known from the remotest ages, and zinc, at any rate, since the birth of modern chemistry, it seems singularly strange that no one ever thought of trying the effects of these two metals on one another until now. To take the case of iron, a merely cursory examination of the second volume of "Percy's Metallurgy" will show that some of the very simplest questions relating to this most common and important metal remain as yet unanswered. Such an apparently vital matter as the formation of steel is a bone of contention at nearly every meeting of the French Academy of Sciences,—one party persisting in declaring that no steel can be made without the intervention of both nitrogen and carbon, while the other side as manfully contend that nitrogen has nothing to do with cementation, carbon being the only element concerned in the process. This example shows that not only does the action of one metal upon another, in a state of combination, require patient study, but also that the effect of the addition of varying proportions of the metalloids, such as carbon, phosphorus, silicon, sulphur, &c., to different metals, is still undiscovered.—*Chemist and Druggist.*

EYE PROTECTORS.

Mr. Henry Vale, of Birmingham, optician, has patented certain improvements in the manufacture of eye protectors—in making the frames and in attaching them to the wire gauze. In making these frames according to the new method the patentee proceeds somewhat as follows:—There is cut out from sheet metal at a press ring: like blanks of a nearly elliptical figure, the said blanks having at opposite points nearly circular pieces to form the loops in the finished frame. By means of raising tools and pressure, these blanks are raised into a trough-like form, and at the same time are raised and perfected the shape of the loops at the end of the frame. There is thus produced a trough-like frame provided with the necessary loops, the sides of the said trough being nearly parallel. Instead of raising the frame from metal rings a raised blank may be formed from sheet metal, the metal inside of, and external to, the depression in the said blank being afterwards removed by cutting dies or tools. In securing the wire gauze of the protector to the frame the edge of the gauze is placed in the trough of the frame, the sides of which are then closed upon the gauze, and the gauze firmly secured to the frame. By raising the frame from sheet metal, a neat frame without a junction is produced, which is attached to the gauze without solder.

BROUGHTON'S GRADUATING LUBRICATOR FOR STEAM ENGINES.

It is important that the valves and cylinders of steam engines should be oiled occasionally, since the friction is not only lessened thereby at the time, but the expense of repair is much reduced. The lubricating faucet here shown is one of the simplest we have ever seen, and is constructed in the best manner and of the most serviceable material. The combination of mahogany and brass give it a neat appearance also, so that it is ornamental to any steam engine. Its parts are few and simple, and a total absence of cocks and valves opening externally, which always wear and become leaky, is its most distinguishing feature, as will be seen by reference to the engraving.

It consists of a reservoir, with a stuffing box at top and a solid central stem, A, passing through the top of the reservoir, and screwing by a thread on its lower end directly into the shank, where it forms an internal valve in connection with a seat in the shank. There is also an auxiliary opening, B, for filling, which is closed by a tubular cap, C.

The central valve, when screwed down, cuts off the communication with the steam chest. The first rotation of the tubular cap, when taking it off to fill, will allow the steam in the reservoir to blow out, in a direction away from the hand of the operator; the

oil can then be poured in, and the air will freely escape. The tubular cap has a composition seat, and forms a durable and perfectly tight joint. When the reservoir has been filled, and the cap replaced, the oil may be graduated to feed fast or slow, as required, by unscrewing the central stem, A, from a sixteenth to a quarter of a turn; or it may be fed at intervals by unscrewing for a few seconds, and then closing it again. The reservoir cannot be filled without leaving a small space, or air chamber, above the oil; into this the steam will rush when the valve is slackened, and the pressure will be equalized, and the oil pass out.

The formation of the stem is shown in the small figure; the grooves admit the oil when the valve is opened.

The central stem may be withdrawn at any time, without disturbing the packing in the stuffing-box, and the shank can be unscrewed from the reservoir. The handles are of wood, and being non-conductors of heat, can be operated without using rags or cotton waste.

This simple arrangement forms a perfect lubricator, serving every purpose and performing every function required in lubricating valves and cylinders. Its advantages are: It will not leak, consequently it is clean, and wastes no oil; it will shut off the steam from the steam chest by an internal valve, not liable to wear; it will blow the steam out of the reservoir without the possibility of scalding the operator; the oil can be poured in without any open cup to catch dust and dirt, and the air can freely escape without the use of pet cock, or air passage: the oil may be all fed to the cylinder in one minute, or it may be graduated to last a whole day.

Manufactured by Broughton and Oakman, No. 41, Centre-street, New York, U.S., America.

ON THE APPLICATION OF SPECTRUM ANALYSIS TO MICROSCOPICAL INVESTIGATIONS.*

By H. C. SORBY, F.R.S.

(Continued from page 308.)

It appears that in various conditions blood yields no less than eight very different spectra. At all events, we can most readily get four or five, so characteristic, that with proper care there could be no fear of confounding it with any other substance that I have hitherto examined, and probably not with any in existence. However, in all important investigations, it would be advisable to examine the spectra of any substance likely to be present. I would also specially insist on the importance of carefully attending to the exact position and character of the absorption-bands; and before anyone gave evidence on such a subject, that he should make himself practically familiar with the facts I have described.

In applying this method to the detection of blood-stains on various articles of clothing, it is requisite to ascertain the effect of the different materials, dyes, and mordants. I have for this purpose made a great many experiments, and yet probably much remains to be learned. As a general rule, the dyes exercise little or no prejudicial influence; but when alum has been used as a mordant, it produces an effect which might easily mislead. Hitherto I have not been able to overcome the effect of the tanning in different sorts of leather. They precipitate the colouring matter of the blood, and no spectra can be obtained. If, indeed, the blood can be scraped off from the surface without any considerable amount of leather, it can be detected as usual; but, if it had been sponged or washed, probably no trace whatever could be detected. The same applies in the case of those woods, which, like oak, contain tannic acid. Vegetable soil, when its amount is large in proportion to that of the blood, also precipitates the colouring-matter in an insoluble form; but, where the relative amount is small, as on dirty clothes, it does not sensibly interfere with the test, though it tends to impair its delicacy.

When scarlet or brown crurine is acted on by a solution of alum, it is converted into hæmatin. If it has been used as a mordant, sometimes a portion remains in such a condition as to produce this change in blood stains; and, moreover, the alumina may combine with the colouring-matter of the blood, and make it insoluble. In such cases it is impossible to obtain the spectrum of either scarlet or brown crurine; but if a piece of cloth, mordanted in this manner, marked with blood, be digested in a few drops of water in a watch glass, and repeatedly squeezed with forceps, a turbid solution is obtained, which, treated with citric acid, filtered, rendered alkaline with ammonia, and deoxidized with protosulphate of iron, shows quite well the spectrum of peroxidized hæmatin No. 8.

In a few cases the colouring-matter of the dye is slightly dissolved by water. I have especially noticed this in the case of black printed calico; and if much of such material, containing very little blood, be digested in water, the dye may cut off the characteristic part of the spectrum. Care should therefore be taken not to use any of the material not well marked with blood, and to have the solution so dilute that the dye may not cut off the green rays.

Almost everyone must have noticed the fact that, when a bloodstain on white linen or calico has been exposed to pure air for only a short time, it can be almost entirely dissolved out by water; but, if dried and exposed for some time, the imperfectly soluble brown crurine cannot be entirely removed, and leaves a brown stain, which, though readily seen on white material, might be scarcely visible on coloured or black. However, on digesting the suspected portion in a few drops of water with citric acid in a watch-glass, and proceeding as already described, a

* Extracted from the *Quarterly Journal of Science*.

most unmistakable spectrum like No. 8 may be obtained, even when the stain is only half-an-inch square, and scarcely visible. In attempting to remove a blood-stain from cloth by sponging, on the first application of the water a solution of blood would be formed, and run into the surrounding cloth by capillary attraction. Hence, though the stain may appear to have been removed, the cloth round about might, and probably would, retain abundance of the colouring matter, which could be dissolved out. Any suspicious marks that might be due to such treatment should therefore be examined with care. Of course, in such cases the microscope alone would be of no avail, and mere chemical tests could not be relied on, and thus the spectrum method becomes especially useful. Specimens of this character having been placed in the hands of some of the first authorities in such inquiries, they said that neither they nor anyone else could make out anything from them; nor would they believe that I could, though the amount of blood was such that in a few minutes I could have shown such a spectrum as No. 8, and have been in a position to give evidence with great confidence.

When soap is present it causes a precipitate; but this is quite soluble in plenty of ammonia, and does not prevent our seeing the spectrum No. 8. Boiling water, instead of facilitating the removal of blood, makes it more fixed, by coagulating the albumen. If the blood be dried on glass, the colour is changed to a brownish red, and it gives a spectrum like No. 5, whether dry or damp. When dissolved by citric acid, it yields hæmatin, and readily gives spectrum No. 8.

In some cases foreign matters, or the mordants, make the solution so turbid that it is difficult to see the spectrum to advantage. If we wish to observe the spectrum of blood in its natural state, or as it becomes by mere exposure to the atmosphere, it is better not to filter, but to allow the solution to stand in the cell in front of the slit, until it has become sufficiently clear; because filtering would probably remove much of the colouring-matter of the blood. However, in some varieties of brown cloth the mordants give rise to such a turbid solution, that it is very difficult to see the spectrum in a satisfactory manner. Citric acid should therefore be added to make the colouring-matter more completely soluble, and the liquid filtered. For such small quantities a blotting-paper filter $\frac{1}{4}$ of an inch in diameter should be used. It can be conveniently supported on a platinum wire bent at one end into a ring, and made to slide up and down a small wire for a support; and if the bottom of the filter touch the cell or watch-glass, though the liquid may pass through slowly, the final result is far more satisfactory. After the acid solution has passed, it is well to add the ammonia by allowing it also to go through the filter, to carry away any colouring-matter, soluble in that reagent, that might remain on the filter.

(To be continued.)

OUR SUBSCRIBERS' NOTES AND QUERIES.

IRON.—What is meant by hydrot pig-iron?—the difference between that and pig-iron? What is burnt iron? what is taken away and what added to it?—WELLINGTON.
VENETIAN BLIND PAINT.—Of what is it made, and how used?—WALSALL.

GALVANOMETER.—How to make a vertical one for ascertaining power of electric current?—A LOVER OF SCIENCE.

CONTACT BREAKER.—How is it made, and how does it work? Where can I learn of the one used for the large coil in the '62 Exhibition?—J. ROUND.

TO MAGNETISE BARS.—How best to strongly magnetise two round bars, about 3 inches long, $\frac{3}{4}$ inches diameter? (I have horse-shoe magnets and electrical apparatus—don't know how to use them); also, best book on subject?—COMUS.

INDUCTION COIL.—In construction, is it necessary to insulate from each other the wires composing the iron core?—T. B. R.

STEEL POLISH.—How obtained, as on flat steel pieces in fine wheel work?—JOHN COWAN.

PAINTING ON GLASS.—How to paint on glass, such as writing on the back in shop-fronts, and making it transparent? I appeal to British workmen.—AN ENGLISH DECORATOR.

BUILDING CONSTRUCTION.—Where to obtain the book used at South Kensington, and one on "Solid Geometry"—sections, traces, pyramids, prisms, &c.; also one on "Perspective," with price of each.—GEOMETRICIAN.

SOLDER.—In repairing brass, how can I give the solder the permanent colour of brass?—DRILL.

POLISHING CASTINGS.—The best way of polishing iron and brass castings, and malleable forgings—sizes of emery requisite, manner of covering the same, and requisite speed for polishing?—A JOHNSTONIAN.

TEST FOR COIN.—Wanted, a good test for bad silver.—JAS. WARD.

ZOFISSA PAPER.—Is Zofissa paper sold in bulk, or only the articles made from it? Where is it sold?—A. M.

PEROXIDE OF BARIUM.—The price of it, where it may be had, or how to prepare it?—CHEMISTS (Derby).

BLURRING SPRINGS.—How to do this without altering the temper, cheaply?—A. SMITH.

POLARISCOPE.—The use of it—what objects look well in it; the difference between that of J. Sargent and O. T. Whitwell; also descriptive dimensions of part of Camera Lucida.—Q. C.

LAPIDARY.—How to cut and polish stones and agates?—DRAKEBEE.

Sir.—Can any of your readers inform me how to bore small brass cylinders? An answer will greatly oblige
J. H. J.

ASTRONOMICAL GLASSES.

Sir.—Can any of your readers inform me how to produce glasses for astronomical instruments in a raw and finished state? Or if any work is published on this subject?
SWEDS.

GALVANIC BATTERY.

Sir.—Can any of your readers inform me of the cheapest and most durable galvanic battery that, with a condenser, would give $\frac{1}{2}$ inch spark? The name and agent will do.
H. BROWN.

[Thanks for sketch.—W. Joyce will find two or three machines illustrated in back numbers.]

CYLINDER NOZZLE.

Sir.—Would any of your correspondents please to inform me what would be the correct size of the passages for the nozzles of a 3 inch cylinder and the proper thickness of the metal for the cylinder and nozzles that size; and if there is a general rule by which we may calculate from that an extension of sizes.
MODELLER.

ALARUM.

Sir.—In answer to Charles Waterhouse I send a rough illustration of an alarum. A, A is a piece of thin charcoal iron

plate, $4\frac{1}{2}$ in square; B, C, D, are three $\frac{1}{2}$ in. studs riveted in plate; E, $2\frac{1}{2}$ in. long; F, $1\frac{1}{2}$ in. long; G, $2\frac{1}{2}$ in. long; H, is a piece of thin charcoal iron, 7 in. long, with bell riveted to end, and made to work on stud B; G is a connecting link made to work on a small crank pin riveted in flange E, 2, to impart eccentric motion; F is a catch $4\frac{1}{2}$ in. long with hole off centre, slipped on to stud C—this completes the affair. Let O, W. fasten this on the wall above his clock, get a piece of twine the length of the wall, tie a weight to the end of it, wind it round the wheel, put the catch in notch of flange E, attach a piece of twine to end of catch, wind up his clock to top, tie catch twine to the weight of his clock, and calculate how many hours it will take for the weight of clock to lift catch; for example, if the weight of clock takes an hour to come down three inches, your catch twine will require to be 21 inches long from bottom of clock to lift the catch in 7 hours. If C, W. has not a common chain clock, he can make a pair of wooden scales and bring the alarum down with either sand or water. The rest I will leave to his own ingenuity.
EDINA.

RESUSCITATION.

Sir.—Can any reader tell me the best way to deal with an old steam engine, grasshopper class, made in 1836. Of these dimensions:—Stroke of piston, 2 feet 6 inches; speed of piston, 250 feet per minute; travel of valve, $3\frac{1}{2}$ inches; lap of valve, 7-16 inches; lead, 0. Admission over 90 per cent. and without governors, and suffering from condensation. I have tried the valves more lately at 2 in. and 1-16 travel, and 75 per cent. admission with 1-16 in. lead; and I find the engine runs a considerable deal better than before as regards steadiness and fuel. But I was obliged to take the lead from the valves, as she heated and knocked the crank shaft journal so greatly. If I have new valves what is the most useful lap and travel; and the greatest useful admission per cent. of stroke. A plain and practical answer through THE ENGLISH MECHANIC will greatly oblige
E. WATSON, Engine Driver.

HAND FLY-WHEEL.

Sir.—I would advise your readers who can, to go to and look into the Agricultural Hall at a hand fly-wheel which has been sent in, and stands near the Liverpool-road entrance. It is as near a perpetual motion as anything I ever saw.
G. KIRKWOODS.

CHUCKS.

Sir.—I am surprised Mr. Cotchett should send a chuck so much like mine (published in your 23rd number). I believe my chuck to be simpler, and stronger, therefore better; and believing it to be original, I venture to enclose it thus much on your space. THOMAS E. MERRITT.

PISTON VELOCITY.

Sir.—I am desirous of ascertaining at what velocity a piston will move, supposing the cylinder to be increased to double its length and the area of the piston to be only one half, whilst the pressure of steam remains the same, and the valves remain the same; for instance, supposing the pressure to be 30 lb., and the cylinder 60 in. long by 8 in. wide, instead of 30 inches long by 16 in. wide. My question is, ought not the piston to move at nearly double the velocity, and if not, why does it not do so?
J. T. MILLINGTON.

PRINTER'S INK.

Sir.—In answer to "New Leeds" in No. 25 of THE ENGLISH MECHANIC, the following is one method of making printer's ink:—Put linseed oil into an iron pot capable of holding two or three times the quantity introduced, heat it over a fire until a dense vapour arises from it; then, having removed the pot from the fire, apply a lighted match, attached to the end of a stick, to the surface of the oil, when the vapour will inflame; allow it to burn, until on taking out a small quantity of the oil, it is found to be thick and tenacious; the flame is then to be extinguished by putting a cover over the pot. To six quarts of oil, thus prepared, add gradually 6 pounds of black resin, and dissolve it by the aid of heat, then add, in small quantities at a time, 12 lb. dry yellow soap, cut into slices, and effect the combination by stirring and the application of heat; this is the varnish of which the ink is to be made, and on the careful preparation of which the quality of the ink much depends; this is to be mixed with $2\frac{1}{2}$ ounces of ground indigo, the same quantity of ground Prussian blue, 4 lbs mineral lamp-black, and 3 lbs. of the best vegetable lamp-black, and the whole ground together into a perfectly smooth and uniform paste. Ink of different colours are made by mixing the varnish with various pigments, such as vermilion, red lead, Indian red, chrome yellow, chrome red, verdigris, Prussian blue &c. &c.
JAMES WARD.

PRESSURE.

Sir.—In reply to "J. Soundle" He asks what pressure per inch he should have in the boiler if a vertical column is suspended in an inch tube 24 feet from top of boiler.

Steam or any fluid that as pressure exerts its force according to the height of the column of water above the sectional area makes no difference. Thus, a column of water suspended 34 feet above the boiler will produce a pressure 15 lbs. per square inch.

The following, I think, will do for a rule:—

$$\frac{15 \times 24}{34} = 10.588 \text{ lbs.}$$

According to rule, the pressure for a 24 feet column will be 10.588 lbs. per square inch.

It makes no difference as to diameter of tube, because the pressure of steam counterbalances every square inch of the area at the base of column.
J. NEWTON.

Sir.—In reply to J. Soundle's query in No 25 of THE ENGLISH MECHANIC, as to the pressure in his boiler, I beg to inform him that the weight of water contained in a pipe 1 in. diameter, and 12 in. long, is equal to 34 lb., and $24 \times 34 = 816$ lbs., the pressure in his boiler.
X. Y. Z.

TO HARDEN COFFEE MILLS.

Sir.—In answer to "Arthur Stillman," of August 11. The way to harden cast-iron coffee mills is to get to blood-red heat, and then potash, finely powdered, sprinkled on till it is melted, and then slacked in cold water.

I have used the above, which answered very well for years.
A. SMITH.

BATTERIES, &c.

Sir.—I beg to answer the following:—E. M., No. 24, Amalgam. Dissolve sealing-wax in wood naphtha, and apply with a brush. If you go over the same place more than once, do it quickly, as the evaporation is rapid.

E. M. No. 25—Induction coil.—Gutta Percha covered wire will do, but is not so desirable as cotton, as the insulation is thick, and increases the distance between the wire and core; thus diminishing the power. A condenser is, I believe, for the purpose of collecting the electricity which would otherwise escape at the points of contact, i.e., the make and break, and discharging it by induction into the secondary wire. Also for preventing, as it were, a Leyden jar forming between the primary and secondary coils, which would tend to spoil the machine.

F. Harwood.—No. 26.—At almost any wire drawer's, or optician's. Ladd, 11 and 12, Beak-street, can supply, no doubt, No. 35 I think. The length to be found is 1,405 yards.

Alfred Cross.—No. 25.—Certainly, and the best way too. A couple constructed on this principle will last 4 months without refreshing. If it be well and properly charged at starting. The cells as described ought to have lasted 2 months at the least. The pots must have been bad—top porous.—Try again, and succeed.

Cells, Coils, &c. &c.—No. 25.—William Tonkes deserves knighthood, and nothing less.

I propose to make an induction coil of the following dimensions:—Core, 12 in. between discs, $1\frac{1}{2}$ diameter. No. 16 annealed iron; primary, 4 convolutions No. 12, 7 strand copper, (cotton). Secondary coil, 6,000 yards. No. 35, silk covered copper wire. Will you or your correspondents kindly inform me whether the dimensions and materials given, are of the order to ensure success, and what results I may anticipate?

I do not remember any mention having been made of the size and number of sheets used by Ruhmkorff in his condenser. Will 24 or less 11 by 6 in. suffice for my coil?

I propose to work this instrument—when made—with 6 elements "Smec" 2 in. by $3\frac{1}{2}$ in.; will this be too much or too little power?
ANATEUR.

Sir,—I have taken the liberty to send directions to enable anybody to make an electrical machine, that will show all the rudiments of electricity for, at most, 2s. :—
Get a disc of tin ten inches in diameter, and have the edge turned up about half an inch all round. Fill it with the following mixture:—

Melt one pound of resin, when melted, add one or two spoonfuls of olive oil, and let it harden. Meanwhile, make a disc of wood 6 or 7 inches in diameter, and cover it with tinfoil; also fix a glass rod in the back to serve as a handle. With a nice dry piece of flannel your apparatus is complete. To use it, warm the flannel, and rub it briskly on the resinous plate; then touch the resin with the tinfoil, and so on.

H. BROWN.
Sir,—In reply to "Mr. Crofts," all the red porous cells I have tried (and some of the thin white ones). Allow the oxide of copper to form on the sines. It would be better, therefore, to charge the cells with silver sand moistened with acidulated water; this will tend to prevent it, and increase the constancy of this battery.

J. ROUND.
ADDRESS ASKED FOR.—Chas. Collins, Microscope Manufacturer, 77, Great Titchfield-street, Oxford-street, W., and at the Polytechnic Institution.

WYLLIE'S PORTABLE STEAM RIVETTER.

The rivetter belongs to the steam-hammer class, and performs the rivetting by a succession of blows. The rivetter is made with a swage tool always, whether for flush rivetting or for snap heads; and this swage tool is held in the front end of the cylinder, and forms a loose plug or plunger not connected with the piston, while the piston itself is an independent bolt or hammer of suitable weight, traversing backwards and forwards like a shuttle in the cylinder, and striking the end of the swage tool within the cylinder. By this arrangement the swage tool or tool-head remains almost stationary, and the length of the machine is reduced to only the length of the stroke of the piston, together with the struck part of the tool-head, the length of the piston, and the thickness of the back cover, and the length required for the stroke outside the cylinder, and for the shuffling box are got rid of altogether. This is not only a saving of length, but also an economic simplification, and does away with the risk of breaking the bottom of the cylinder by an unobstructed stroke of the hammer, since the tool-head, being entirely loose in the cylinder, act as a safety bottom to the cylinder. In rivetting, the tool-head simply follows the rivet, as it is hammered up and remains in contact with it, so that the workman has to look at an almost stationary tool-head instead of at a rapidly moving hammer, and he can, therefore, better adjust the position of the machine to the proper formation of the rivet head. The machine is of such a size that the workman can hold it in its position independent of its mechanical fixings. With steam at sixty pounds pressure per square inch, it is found sufficient to make firm work with 1½-inch rivets. The machine weighs thirty-six pounds, and is perfectly portable. It is Mr. M'Farland Gray's patent. At straightforward work, such as the side of the Britannia Tube, it will fix fifteen hundred 1-inch rivets in a day of ten hours, and does not require skilled labour. Two men work the machine, and are supplied with rivets by rivet lads in the usual way.

THE ORIGIN OF PHOTOGRAPHY.

The Rev. J. B. Reade has called attention to the fact that Baron Liebig, in stating that "Mr. Talbot arrived at the use of gallic acid by induction, makes an error. Mr. Reade, who was the first to use gallic acid, had really informed Mr. Talbot of its properties in accelerating and giving intensity to the photographic image. Mr. Reade had produced photographs with the aid of gallate of silver years before Mr. Talbot. It was, moreover, when taking an impression direct from the *Trialistis Europæa*, and not when using the solar microscope, that Mr. Reade, being called away, afterwards found a perfect impression on paper which had been thrown away, containing no image. Mr. Reade remarks that, singularly enough, even then the notion of the existence of a latent image did not enter into his mind. The recognition of the idea of a latent image capable of development Mr. Reade considers due to Mr. Talbot. It must not be forgotten, however, that the existence of a latent image and a process of development had first been discovered by Daguerre. We note these corrections by Mr. Reade with pleasure in the interest of historic truth. In a few years there will be no living witnesses to give their testimony on these points.

THE Union Copper Mine, at Copperopolis, during the month of June, shipped from the mine to San Francisco, via Stockton, the large amount of three thousand six hundred tons of ore, the freight money on which was 29,000 dolars.

IMPROVED T POLISHER.

This tool, which is indispensable in polishing a job (underhand) perfectly flat, is perhaps unknown to some of those readers of THE MECHANIC who are engaged in the horological art. I have no doubt, therefore, that the accompanying drawings and description of a T, or underhand polisher, will be found very useful. The drawings are twice the actual size of the tool. It is made of brass, and mainly consists of two pieces, the stock, or T (hence its name), A, and the clamp piece B. My improvements are, 1st, the securing of the elevating or surface screws from shifting when in use. 2nd, applying an independent piece for attaching with shellac or wax, jobs which are too delicate to be held in the clamp piece. The elevating screws C, C are used for adjusting the tool to the level of the job to be polished, while the screws D, D are for securing the job between the clamp piece and the polisher. The usual method of securing the elevating screws when set is by pinching nuts, as shown by the

dotted lines at E, E; but in a short time these get too free or loose upon the screws; the result of which very often being that having got your job perfectly flat, and a beautiful polish coming up, you discover that one of the screws has made a shift which compels you to flatten your job over again. To prevent this, I have run a saw daught, F, F, down the top of the polisher, and put in two pinching screws, G, G, the slightest turn of which effectively secures the elevating screws, so that there is no possibility of their shifting when the tool is in use. In order to polish anything delicate, it has (as before mentioned) to be secured to the tool with sealing wax or shellac. For this purpose I have a brass disc, H, which is held in the polisher by the stud I; it is easily removed for the purpose of heating, thus obviating the necessity for heating the whole tool, as is usually done. Figs 2 and 2A shew the disc with a Geneva rochet click fixed in position for polishing.

JOHN MCKAY.

THE resistance of the air to a cannon ball of 2 lb. weight, with a velocity of 2,000ft. per second, is more than sixty times the weight of the ball.

VEGETABLE ivory may be coloured almost any shade of purple by the more or less prolonged action of concentrated sulphuric acid.

SILVER can be beaten into plates of which 110,000 make an inch, and drawn into wire of the 13th of an inch, sustaining 137 lb.

SCIENTIFIC DODGES.

It is well known that ink is a precipitate of gallate of iron mixed up and kept in suspension in gum and water. As the water evaporates the ink thickens, and, moreover, becomes mouldy owing to a small proportion of organic matter proceeding from the gall-nut. M. Mathieu Plessey has got rid of these inconveniences, by making a new kind of ink with pyrogallic acid and the colouring matter derived from Brazil wood and other sorts of wood used in dyeing. This ink flows well, and never turns yellow on paper. Dr. Werner, physician to the factory of M.M. Dollfus at Mulhausen, treats wounds and sores of every kind with a liniment thus composed:—Strasbourg turpentine, 1,000 grammes; bicarbonate of soda, 25 grammes; distilled water, 10 litres. Digest for six days in a water-bath at a temperature not exceeding 75° centigrade, and filter. This is a sort of turpentine soap, much more soluble in water than turpentine itself. It evaporates but slowly and costs very little. Most wounds are cured in one-third of the time required by other applications. In some cases the wound heals with extraordinary rapidity, but in all its appearance is healthy, and very little suppuration takes place—a very important circumstance, since it prevents the danger arising from purulent infection. Radishes may be grown in a very few days by the following method:—Let some good radish seed soak in water for twenty-four hours, then put them in a bag and expose it to the sun. In the course of the day germination will commence. The seed must then be sown in a well manured hot-bed, and watered from time to time with lukewarm water. By this treatment the radishes will in a very short time acquire a sufficient bulk, and be good to eat. If it be required to get good radishes in winter during the severe cold an old cask should be sawn into two, and one half of it filled with good earth. The radish seed, beginning to shoot as before, must be then sown in, the other half of the barrel put on the top of the full one, and the whole apparatus carried down into the cellar. For watering lukewarm water should be used as before. In the course of five or six days the radishes will be fit to eat.—*Galignani's Messenger.*

THE magnesium light is found to be sufficiently active to determine the combination of hydrogen and chlorine.

A CUBIC inch of mercury at 63.30 deg. weighs 3425.35 grains.

PATENT LIST.

(From the Commissioners of Patents' Journal.)

LIST OF SPECIFICATIONS, &c., PUBLISHED DURING THE WEEK ENDING 16TH SEPTEMBER, 1865.

- 2661. Tramping, wringing, and delivering yarns, J. Stobo and W. Pollock.—1s. 4d.
- 2662. Axles and bearings, J. Craven and R. Fox.—4d.
- 2663. Fitting axle, W. Congdon.—1s. 6d.
- 2664. Artificial stone for cutting metallic surfaces, E. J. W. Parnacott.—4d.
- 2665. Sextants, &c., R. A. Brown.—1s.
- 2666. Exhausting, forcing, &c., and applying aeriform bodies, W. Law, and J. Robertson.—3s. 6d.
- 2667. Sewing machines, W. Jackson.—1s. 2d.
- 2668. Sizing or dressing yarns or fabrics, J. Charlton, H. Charlton, and J. O. Christian.—4d.
- 2669. Fire-arms and projectiles, J. P. Harris.—4d.
- 2670. Signalling in railway trains, W. Dowley.—4d.
- 2671. Brushes, J. Goodall and F. Goodall.—4d.
- 2672. Sheathing ships, G. Ager.—4d.
- 2673. Distilling matters to obtain liquid or gaseous hydrocarbons, W. Cornack.—1s. 6d.
- 2674. Hydraulic engines for obtaining motive power, G. Bydill.—4d.
- 2675. Preparing compounds of gun cotton and other substances, &c. A. Parker.—4d.
- 2676. Laces, J. Hartshorn, and J. Gadsby.—4d.
- 2677. Rails and bearers for railways, H. A. Jowett, J. E. Jowett, and J. B. Muschamp.—8d.
- 2678. Centrifugal apparatus, A. Smith, and W. Smith.—10d.
- 2679. Rolling or shaping metallic articles of irregular form, J. L. Davies.—4d.
- 2680. Material for panels, &c., A. H. A. Durant and W. H. P. Gore.—4d.
- 2681. Motive power, L. F. G. Bellot, and C. M. P. De Bouvres.—10d.
- 2682. Bolts, W. Clark.—6d.
- 2683. Hooks, H. Larkin.—4d.
- 2684. Farinaceous food, B. R. Keith.—4d.
- 2685. Tenting, stretching, and drying fabrics, &c., J. L. Norton.—3s. 4d.
- 2686. Syphons, G. H. Devereux.—8d.

C. SUFFELL, MATHEMATICAL INSTRUMENT MAKER, 11, BRIDGE-STREET, WESTMINSTER, begs to call attention to his Improved Levels and Theodolites, as manufactured for Her Majesty's Government. The pocket sets of Instruments, from 16s. to 42s.; Telescopes, 5 miles range, from 6s. 6d.; 10 miles ditto, 8s. 6d. and 10s. 6d.; Boxwood scales, engine divided, 2s. 6d.; T squares, 1s. to 5s.; Measures and Rules of all nations. Post-office orders payable at Charing Cross branch. Lists of prices forwarded on application.

THE LONDON DRAWING ASSOCIATION for supplying Engineering, Mechanical, Architectural, and General Drawing, Designs, Maps, Plans, Tracings, Wood Engraving, Electrotyping, 7, Duke-street, Adelphi, London. Enclose stamp for prospectus.

cery-lane, W.C.

**W. LANGTON'S
PATENT
SELF GENERATING
GAS STOVE**

**BOILS or Frys by Methy-
lated Spirits generated
into Gas, free from smoke
or smell, and is the most
useful and economical in-
vention for the purpose
ever offered to the public.**

Sold by all Ironmongers,
and at the Manufactory,
36, CHARLES-STREET,
HATTON-GARDEN.

**CIRCULAR SAW FENCES
FOR FOOT OR STEAM POWER**

Suitable for Cuttin'
Brass, Ivory, Hard-woods, Picture-frame Work, &c.
All kinds of Machinery made to order.

HUMPHREY AND HASLER, 69, Old-street, St. Luke's,
London, E.C.

WHEEL, RACK, and SCREW CUTTING.
SPUR, BEVEL, RATCHET, WORM and INTERNAL
WHEELS cut to any size or number of teeth; also racks of any
length or pitch. Dividing plates drilled or lined. Screws cut to any
size or pitch. J. Wilkinson, Engineer, St. George's Works, 83, St.
George's-road, S. London.

**TUCK'S PATENT STEAM
PACKING.**

**TUCK'S PATENT ELASTIC
PACKING and METALLIC
LININGS FOR STEAM-EN-
GINES, PUMPS, &c.**

ADVANTAGES.—A more perfect
vacuum is obtained. Friction
reduced, great saving in oil and
tallow, and the Packing is gradu-
ally and completely worn
away without becoming hard,

THUS OBVIATING THE NECESSITY OF DRAWING THE OLD
PACKING.

hand, Bookkeeping, Arithmetic, Geometry, Algebra, Chem-
istry, Electricity, Magnetism, Practical Mechanics, and Mechanical
Drawing taught by post by Wm. BROOK, Postal School, Almondsbury,
Huddersfield. Lesson, 4 stamps (free).**

**HEWITT'S PATENT COMPOSITION, for
the REMOVAL and PREVENTION of INCrustation in
STEAM BOILERS.**

In submitting to the public, William Hewitt's Patent Composition
Preventive of the incrustation in boilers, the inventor begs to direct
attention to the peculiar merits of his discovery, consisting of ANIMAL
MATTER free from injurious acids and volatile ingredients. Being,
for the most part, mechanical in its action, it covers the boiler and
tube surface with an unctuous coating which detaches, where formed,
or prevents the adhesion of saline or other deposits on the boiler
surface.

The composition is manufactured in a block, or solid form, which
is inserted (through the man-hole) in the boiler, when its properties
are progressively developed, and generally diffused by heat, as the
substance is slowly dissolved.

Although the gauge-pipe will show the water to be slightly dis-
coloured, it is nevertheless wholly innocuous, indeed in some parts of
the West of England where the composition is used, the water is
applied to many domestic purposes, and also for dressing the food for
the cattle employed in the manufactories and farms.

The inventor is justified in asserting, from the experience of trials,
(extending over two years) and inquiries made up to date, that the
unctuous and other properties of the composition, do not cause but
prevent priming, and not only tend to preserve the boiler from in-
crustation, (which occasions great loss of heat and often causes the
crown of the furnace to be burned) but will also remove incrustation,
however aggravated.

Its advantages over the LIQUID compositions are so obvious as
scarcely to require comment, though it may not be inexpedient to
observe that the difficulties and restrictions attending these in
respect to "blowing off," &c., are entirely obviated in this invention.

Danger from contact with the valves in the boiler, need not be
apprehended, as the specific gravity of the composition is so great,
that it is only slightly moved on the bottom of the boiler by the
ebullition of the water.

The inventor trusts that the novel and favourable character of the
composition as displayed in its immunity from any injurious
qualities, or volatile ingredients, simplicity in application, and
lengthened time during which it will continue to yield beneficial
effects without renewal, may ensure it a fair trial, when it will be
found to have done its duty well and effectually.

It is confidently believed that in a little time hence, when its
economy and safety are more widely known, that it must become the
Composition of universal consumption.

The cash price is fixed at 4s. per cwt., equivalent to THREE FAR-
THINGS PER HORSE POWER, PER WEEK; an infinitesimal figure, as com-
pared with the increased consumption of fuel occasioned by an in-
crusted Boiler, loss of effective power, and proportionate injury to
Boilers and furnaces.

All communications to be addressed to—
JAMES HARRIS,
Manager and Principal Agent for the Inventor and Manufacturer,
Temporary Office—
9, CAMBRIDGE STREET, PICCADILLY, LONDON, S.W.
September 1865.

DIRECTIONS FOR USE.

Cut, or saw, off as many pounds of Composition as there are nominal
horse power of Engine, and put it in the Boiler through the man-
hole; this will be a sufficient quantity for six weeks' duration.
Where Boilers are opened only in two or three times, it will be neces-
sary to add one-third more in weight of the Composition, and so on
in proportion, for example:—

A 30-H.P. Boiler cleaned every six weeks requires 30 lbs.
In all cases where a Boiler is dirty, it is desirable to put in a double
quantity to remove existing incrustation.

The nature and effect of this Composition are such as to enable the
muddy sediment in the Boiler to be blown off whenever desirable,
without diminishing the effectiveness of the Composition which
remains. Particular attention is requested to the Testimonials
from Messrs. Hewitt and Messrs. James Harris and Co., as regards
its application and effects on clean and dirty (incrustated) Boilers.

TESTIMONIALS.

"Upton Lovell Mills, near Hertsbury, Wilts,
"18th June, 1865.

"Mr. William Hewitt,
Dear Sir,—In reply to yours, we have pleasure in stating that,
having used your "Patent Anti-Incrustation Composition," in two
of our large Cornish circular boilers, since July and August, 1865, we
can confidently recommend it as being a most efficacious article;
FURNACE or TUBE BOILERS HAVE HAD A PAKKAGE USED IN TANKS since we
began the use of the Composition, and our Engineer assures us that
both of them are now as free from incrustation as when new, and
have been so for some 18 months.

"We feel convinced that if the Composition were used in a new
boiler, incrustation would take place during its use.
(Signed) We remain, Dear Sir, Yours faithfully,
"H. & S. J. Hewitt,
"Clio Manufacturers.

"(N.B.—In explanation of the above, it should be stated that the
trials were carried on in Messrs. Hewitt's Manufactory.")
"3, 5, and 83, Old-street, London, E.C.,
"16th June, 1865.

"Dear Sir,—We have tried your Composition in one of our multi-
tubular boilers, and find it answers well for preventing incrustation.
We intend adopting the use of it in future, and will recommend it
as an article that will answer its intended purpose.
(Signed) "We are, Dear Sir, Yours truly,
"Mr. W. Hewitt."
"RICHARD MORELAND & SON,
"Millwrights and Engineers.

"Patent Wheel Works, Newington Causeway, London, S.,
"2nd July, 1865:
"Dear Sir,—We have much pleasure in bearing our testimony to
the complete efficacy of your Boiler Incrustation Patent Preventive
Composition. We put 14 lbs. into a 10-horse boiler, and at the end
of 15 weeks had the boiler opened, and found all the old incrusta-
tion removed (if send you a specimen of it as swept out by the
Engineer), and the boiler otherwise clean and uninjured. We have
not found any ill effects whatever to the machinery from its use.
It is our intention to continue its application, as it is far superior,
in every way, to anything we have ever used.

"We are, Sir, Your obedient servants,
"JAMES BERRY & SON.
"King's Road Wire Works, 135, King's-road, Chelsea,
"September 11th, 1865.

"Mr. Hewitt,
"Sir,—I can, with confidence recommend your Patent Composition
as being the most efficient compound yet introduced for the removal
and prevention of incrustation in Steam Boilers. In order to test its
capabilities, I applied it to my Boiler previous to its periodical
cleaning; the composition remained in three months, and, upon
inspection, I found the Boiler perfectly free from all traces of in-
crustation.
"I remain, Sir, Yours obediently,
"C. W. STANDISH."

N.B.—The Composition is now undergoing further trials in Marine,
Locomotive, and Agricultural Boilers, and the results will be
published so soon as they shall be received.

**HEWITT'S PATENT BLOCK COMPOSI-
TION.** Gentlemen of intelligence, energy, and integrity,
liberally dealt with in undertaking the Agencies of Towns, &c., not
yet represented. Apply by letter only, as above.

NEW WORKS PUBLISHED

BY

**E. & F. N. SPON,
16, BUCKLESBURY.**

Just published, 8vo. cloth, price 12s.

PRACTICAL SPECIFICATIONS of WORKS
executed in ARCHITECTURE, CIVIL and MECHANICAL
ENGINEERING, and in ROAD-MAKING and DRAINAGE; to which
are added a Series of practically useful Agreements and Reports.
By JOHN BLENKARN, Civil Engineer and Architect.

London: E. & F. N. Spon, 16, Bucklebury.

Royal 82mo. roan, price 5s.

**A HANDBOOK FOR ARCHITECTURAL
SURVEYORS, and Others Engaged in Building.**

By JOHN THOMAS HURST, C.E.

Formulae useful in Designing Builders' Work.
Tables of the Weights of Materials used in Building.
Memoranda connected with Builders' Work.
Architectural Mensuration.
Constants of Labour.
Valuation of Property.
Summary of the Practice in Dilapidations.
Scale of Professional Charges for Architects and Surveyors, with
various useful Tables and Memoranda.

London: E. & F. N. Spon, 16, Bucklebury.

Just published, elephant folio, cloth, price £3 2s.
Kept also in Lamp Binding at the same price (can be rolled up in a
small compass without injury to the plates).

**PRACTICAL ILLUSTRATIONS of LAND
and MARINE ENGINES,** showing in Detail the Modern
Improvements in High and Low Pressure, Surface Condensation,
Superheating, together with Land and Marine Boilers.
By N. P. BURGESS, Engineer.

London: E. & F. N. Spon, 16, Bucklebury.

Royal 82mo. roan, 4s. 6d., post free.

**RULES for DESIGNING, CONSTRUCTING,
and ERECTING LAND and MARINE ENGINES and
BOILERS.**

By N. P. BURGESS, Engineer.

London: E. & F. N. Spon, 16, Bucklebury.

Eighth Edition, in royal 82mo. roan, price 4s. 6d. post free.

**A POCKET BOOK of USEFUL FORMULAE
and MEMORANDA,** for Civil and Mechanical Engineers. By
GUILDFORD L. MOLESWORTH, Memb. Inst. C.E.

London: E. & F. N. Spon, 16, Bucklebury.

Just published, on a Sheet, price 1s.

**DELANEY and OKE'S WAGE TABLES for
ENGINEERS, SHIP-BUILDERS, CONTRACTORS, BUILDERS,
&c.,** from a quarter of an hour, in regular progression, to nine hours
and three-quarters, from one day to ten days, at 1s. to 8s. per
day.

London: E. & F. N. Spon, 16, Bucklebury.

Just published, royal 8vo. price 7s. 6d.

**THE SEWING MACHINE: Its History,
Construction, and Application.** Translated from the German
of Dr. HERZBERG, by UPFIELD GREEN. Illustrated by Seven
large folding Plates.

London: E. & F. N. Spon, 16, Bucklebury.

600 pages, crown vo., price 10s. 6d.

PERPETUAL MOTION. Its History during
Three Centuries; with ample Descriptions and Illustrations.
By HENRY DICKER, Civil Engineer.

London: E. & F. N. Spon, 16, Bucklebury.

Royal 8vo., cloth, Illustrated with 41 Plates, price 16s.

**A PRACTICAL TREATISE on the SCIENCE
of LAND and ENGINEERING SURVEYING, LEVELLING,
ESTIMATING QUANTITIES, &c.,** with a General Description of the
several Instruments required for Surveying, Levelling, Plotting, &c.
By H. M. MEHRETT.

London: E. & F. N. Spon, 16, Bucklebury.

Just Published, royal 4to., half-bound, Illustrated by 84 Plates of
Furnaces and Machinery, price 45s.

**THE IRON MANUFACTURE of GREAT
BRITAIN,** Theoretically and Practically Considered; including
Descriptive Details of the Ores, Fuels, and Fluxes employed; the
Preliminary Operation of Calcination; the Blast, Refining, and
Fining Furnaces, Engines and Machinery, and the various Pro-
cesses in Union, &c. By WILLIAM THURAN, C.E., formerly En-
gineer at the Dowlais Iron Works, under the late Sir John Guest,
Bart., subsequently at the Herwain and Forests Works, under Mr.
Crawshaw. Third Edition revised from the Manuscript of the late Mr.
Thuran. By J. Arthur Phillips, Author of "A Manual of Metallurgy,"
"Records of Mining," &c., and W. H. Dorman, C.E.

London: E. & F. N. Spon, 16, Bucklebury.

Just Published, post 8vo. cloth, 3s. 6d.

**MEMOIRS of the DISTINGUISHED MEN OF
SCIENCE OF GREAT BRITAIN, LIVING A.D. 1867-8.** By W. S.
WALKER, Jun., with an Introduction by Robert Hoad, F.R.S.
Second Edition, revised and enlarged.

Containing the lives of Watt, Rennie, Telford, Mylne, Jessop,
Chapman, Murdoch, the first to introduce gas into practical use;
Rumford, Huddart, Boulton, Brunel, Watson, Bentham, Mandesley,
Dalton, Cavendish, Sir Humphry Davy, Wollaston, Hatchett, Henry,
Allen, Howard, Smith, the father of English geology; Gromport,
inventor of the Spinning Mule; Cartwright, Tennant, Ronalds, the
first to successfully pass an electric telegraph message through a long
distance; Charles Earl Stanhope, Trevithick, Nasmyth, Miller, of
Leamington, and Symington, the inventors and constructors of the
first practical Steamboat; Professor Thomson, of Glasgow; Trough-
ton, Donkin, Congreve, Harschal, Maekelney, Baily, Frodham,
Lea, Playfair, Rutherford, Dollond, Brown, the Botanist; Glibers
and Banks, the Presidents of the Royal Society at that epoch of
time; Capt. Ester, celebrated for his pendulum experiments; Dr.
Thomas Young, and Jenner, the benefactor of mankind; Jas. Ivory,
Dr. Priestly and Cort, the father of the iron trade.

London: E. & F. N. Spon, 16, Bucklebury.

UPFIELD GREEN,
JOINERS' HALL BUILDINGS, 79, UPPER THAMES STREET, E.C.,
LITHOGRAPHER, PRINTER, ARTIST, AND DESIGNER,
 PLANS, DESIGNS, SPECIFICATIONS, AND EVERY DESCRIPTION OF ENGINEERING DRAWINGS EXECUTED WITH
 RAPIDITY AND ECONOMY.

Just published, 32mo., cloth, 6d.
ROAD LOCOMOTIVES, an Epitome of the
 New Road Locomotive Acts for the use of Owners and Drivers,
 with an introductory preface, by Thomas Aveling, London.
 E. and F. N. Spon, 16, Bucklersbury.

In case, folded for the pocket, or on roller, price 3s.
DR. REEHORST'S ENGINEERS', Manufactur-
 turers', and Miner's VADE-MECUM: giving in five languages,
 300 technical terms in common use among Engineers, Manufactur-
 turers, Miners, &c. London: F. Pittman, 20, Paternoster-row, E.C.

SCREW CUTTER'S GUIDE,
 Price 1s. 6d., or stamps.
 Containing 115 Pages and nearly 2,000 Trains of Wheels, all different
 threads and pitches.
 Tables for Tap making for Engineers, $\frac{1}{4}$ to 6 inches, Gas Taps $\frac{1}{16}$ to
 inches, Mr. Whitworth's thread and make.
 A Lithograph showing a new radius gear invented by the author
 of this work.
 May be had at James Martin, 19, Wilson-street, New Cross-road,
 Deptford, Kent.

PATENT DISPLACEMENT LUBRICATOR
 FOR LUBRICATING THE PISTONS, CYLINDERS,
 AND VALVE FACES OF STEAM ENGINES.

THIS Lubricator is very simple, efficacious, requires little attention,
 has no mechanism to be deranged, effects a great saving of the
 Lubricant, and a reduction of friction, and consequently of the working
 faces exposed to the steam. It is applicable to every form of Steam
 Engines, Marine, Stationary, Locomotive, and Agricultural, Steam
 Hammers, and other Machines actuated directly by Steam. Prices,
 26s. 6d., 35s. 6d., 45s. 6d. Particulars to be had of the Manufacturer,
J. CASARTELLI, 43, Market-street, Manchester.

No Fitter or Turner should be without a Straight-edge.

The most reliable tool of this kind, graduated to the Standard Measure of the Realm, and
 manufactured with MARVELLOUS ACCURACY, may be obtained of

RICHARD LLOYD,
MILL AND MACHINE IRONMONGER,
 135, STEELHOUSE LANE, BIRMINGHAM.

Clubs of Workmen supplied at reduced prices. No equal tool is sold under FOUR TIMES THE PRICE

CHANGE WHEELS FOR SCREW-CUTTING LATHES.

NOTICE TO INVENTORS.—Office for
 Patents, 4, Trafalgar-square, Charing-cross. Printed
 instructions (gratis) as to the Cost of PATENTS, for Great
 Britain or foreign countries. Advice and assistance in
 disposing of or working inventions. Branch offices and
 agencies in every Continental State and in America.
 Established 30 years. Full information as to expired or
 existing Patents at home or abroad. Apply personally or
 by letter to Messrs. PRINCE and Co., Patent Office, 4,
 TRAFALGAR-SQUARE, CHARING-CROSS, W.O.

TO INVENTORS.—GENERAL
PATENT OFFICES.—L. de FONTAINEMOREAU,
 4, South-street, Finsbury, London; 19, Rue de la Fidelité,
 Paris; 32, Rue des Minimes, Brussels. Provisional pro-
 tection, £7; to complete patent, £20; French patent,
 £6 10s.; Belgium, £2 10s. Circular gratis on application.

INVENTIONS PROTECTED BY
PATENT OR REGISTRATION, at fixed and most
 moderate charges. The Inventors' Manual free by post,
 or gratis on application.—Apply to Mr. BREWER (late
 Barlow and Co.), 89, Chancery-lane, London, W.C. Es-
 tablished 21 years.

EMBOSSER AND ENVELOPE MAKER,
MACHINIST,
 PRESS AND BRASS LABEL MANUFACTURER,
 246, HIGH HOLBORN.

HOLLOWAY'S OINTMENT AND PILLS.—
 BILIOUSNESS—DYSPEPSIA—There is no organ in the
 human body so liable to derangement as the liver. Food, fatigue,
 climate, anxiety all disorder its action and render its secretion—the
 bile, more or less depraved, superabundant or scanty. The first symp-
 toms should receive attention. A pain in the side or top of the
 shoulder, a harsh cough and difficulty of breathing, are signs of liver
 disease which are removed without delay by friction with Holloway's
 Inestimable Ointment. The Pills should be taken early. For all
 diseases of this vital organ the action of these conjoined remedies is a
 specific by checking the over supply of bile, regulating its secretion
 and giving nervous tone.

PATENT HOLLOW STEAM PACKING.

THE great and peculiar advantages of this packing consist in its remaining perfectly elastic, and is so constructed and applied that the pressure of the steam itself makes the joint by entering the packing from the cylinder; thus the many objections to packing previously existing are effectually removed.

Vulcanised India-rubber Sheet Washers, Valves, Springs, Hose, Glazed and Solid Tubing for Gas, Speaking Tubes, Diving Dresses, Gas Bags, Air-proof Goods, or any description of India-rubber articles made to order.

Price list or circular, with full description of packing, to be had of the only Manufacturers and Patentees of Hollow Steam Packing.

FOSTER and WILLIAMS, India-rubber Works, Cowper-street, City-road.

LUBRICATING OILS.—By a newly discovered process (without acids) all gummy and sticky matter is perfectly removed. This oil, being a pure fatty substance, with a dense consistency, accelerates the motion of machinery, is more durable and economical than any in use. Cash prices—spindle and sewing machine oil from 4s. 9d. to 5s. 3d.; dense oil for heavy machinery, from 5s. to 5s. 9d.—Oil Wharf, Stainsby-road, Limehouse, London, E.

JOHN SHEPPARD, of 10, Marsden-square, Manchester, has specially adapted himself for the supply of **ENGINE-CLEANING WASTE**, at the following prices: White at £32 per ton; grey, £25 per ton; coloured, £21 per ton. Wadding Material, for wadding manufacturers, at equally low prices, in bleached, crimson, grey, and black. Liberal terms to shippers.

TO ENGINEERS (Civil and Mechanical), Patent Agents, Inventors, Architects, Builders. Iron Founders, &c.

Patterns for Castings, Models for Locomotive and other Engines, Ships, Carriages, Bridges, Permanent Way, and every description of Machinery made to order, Templates, Working and Finished Drawings, Tracings, &c., Models, and Plans for Trials.—New Inventions practically carried out full size or to any scale. Iron, Brass, and Malleable Iron Castings supplied, by **MACMORRAN & CO., 140, Salisbury Court, Fleet-street, E.C.** Agents for Lenoir's Patent Gas Engines.

N.B. Prospectuses and space papers for the City of London Working Classes Exhibition, and all information given.

W. R. GIBSON,
DRAUGHTSMAN AND ENGRAVER ON
WOOD, LITHOGRAPHER, &c.
EAST TEMPLE CHAMBERS, WHITE-
FRIARS STREET, LONDON, E.C.

THE EVAPORATER SURFACE CONDENSER (PERKINS'S PATENT).—This simple apparatus, having now been in use for some years, can be strongly recommended as very effective and economical.

A vacuum of 26 in. can be readily obtained by evaporation alone, and all the water now required for the ordinary condenser is dispensed with entirely, and pure water is returned to the boiler, thus avoiding all sediment, &c. In non-condensing engines the water is returned to the boilers at a temperature of 212 deg.; and, by the addition of a donkey air-pump, all the advantages of a condensing engine is obtained.

References and estimates given on application to the Manufacturer and Patentee, **A. M. PERKINS, 6, Seaford-street, Regent's-square, London, W.C.**

INVENTORS ASSISTED

IN Securing, Carrying Out, and Disposing of their Inventions.—Apply to **Messrs. B. BROWNE and CO.,** British and Foreign Patent Office, 49, King William-street, London-bridge.

A Pamphlet gratis, on Cost of Patents, may be had on application.

PRIZE MEDALS.

INTERNATIONAL EXHIBITION, CLASS I. AND II.

PATENT PLUMBAGO CRUCIBLES.

The Crucibles manufactured by the **PATENT PLUMBAGO CRUCIBLE COMPANY** are the only kind for which a MEDAL has been AWARDED, and are now used exclusively by the English, Australian, and Indian Mints; the French, Russian, and other Continental Mints; the Royal Arsenal of Woolwich, Brest, and Toulon, &c. &c.; and have been adopted by most of the large Engineers, Brass Founders, and Refiners in this country and abroad. The great superiority of these Melting Pots consists in their capability of melting on an average Forty Pourings of the most difficult metals, and a still greater number of those of an ordinary character, some of them having actually reached the extraordinary number of 96 meltings.

They are unaffected by change of temperature, never crack, and become heated much more rapidly than any other crucibles. In consequence of their great durability the saving of waste is also very considerable.

The Company have recently introduced Crucibles especially adapted for the following purposes, viz.:—**MALLEABLE IRON MELTING**, the average working of which has proved to be about SEVEN DAYS; **STEEL MELTING**, which are found to SAVE NEARLY A TON AND A HALF OF FUEL TO EVERY TON OF STEEL FUSED; and for **ZINC MELTING**, lasting much longer than the ordinary Iron pots, and saving the great loss which arises from mixture with iron.

The Patent Plumbago Crucible Company likewise manufacture and import Clay Crucibles, Muffles, Portable Furnaces, &c., Stove Backs, all descriptions of Fire Standing goods, and every requisite for the Assayer and Dentist. For Lists, Testimonials, &c., apply to **THE PATENT PLUMBAGO CRUCIBLE COMPANY, BATTERSEA WORKS, LONDON, S.W.**

LLEWELLINS & JAMES,
BRASSFOUNDERS,
COPPERSMITHS, AND ENGINEERS,
BRISTOL
Sole Makers of Clements'
ECONOMIC LUBRICATOR,
FOR MARINE, LOCO, AND FIXED STEAM-ENGINES.

(As supplied to the Admiralty, and many Engineering and Steamship Companies.)

This Lubricator offers a perfect method of lubricating all the internal parts of the steam-engine, by the vapourisation of the lubricant, saving, at least, half of the oil or tallow generally used, and lessening the "wear and tear" consequent upon imperfect lubrication.

PRICES, COMPLETE, WITH GUN-METAL FITTINGS:—

2 Pints, 62s. 6d.; 3 Pints, 67s. 6d.; 4 Pints, 75s.

BRIGHT GUN-METAL BODIES, EXTRA.

As they are fixed on the steam-pipe, the diameter of this should be given; and it should also be stated whether horizontal or vertical.

BRITISH AND FOREIGN PATENTS AND THE REGISTRATION OF DESIGNS.

Mr. H. H. MURDOCH having succeeded to the business of his late Father, which has been established nearly Thirty Years, offers his professional services to inventors. A circular, containing full information respecting the various modes of securing protection for inventions at home and abroad, may be had, Gratis, by applying (personally or by letter), at his **OFFICE FOR PATENTS, 7, STAPLE INN, LONDON.**

PATENTS.

MR. VAUGHAN, Member of the Society of Arts, British, Foreign, and Colonial Patent Agent, 54, Chancery-lane, W.C.

ENGLISH MECHANIC:

A Record of Mechanical Invention, Scientific and Industrial Progress,
Building, Engineering, Manufactures, Arts, &c.

Vol. II.—No. 28]

FRIDAY, OCTOBER 6, 1865.

[PRICE ONE PENNY.]

ANDREW'S ELEVATED RAILWAY.

ELEVATED RAILWAY FOR BROADWAY, NEW YORK.

The inventor of this railway, Mr. P. Andrew, of Cincinnati, Ohio, has kept three things constantly in view, which he claims, as follows:—First, a light superstructure; second, one that would occupy the least space; third, a capacity for carrying passengers adequate to the requirements of Broadway.

A single row of pillars, A, support four tracks—the two upper tracks from a distinct roadway, the two lower ones another—each having an up and a down track. The pillars are placed on the outer edge of the sidewalk, in range with the line of curbstones, having sills cast upon them that extend the length of the arms that sustain the tracks, and in

the same direction; these are bolted upon heavy blocks of stone, B, that are placed beneath the sidewalk extending under the street. As will be seen in the engraving, the pendant parts, C, of the arms have projections for the outer rails of the lower tracks, the inside rails are supported from projections from the pillars; upon these projections are placed the chairs upon which the rails rest and are fastened. The chairs for the upper rails are placed upon the upper edge of the arms. The rails are supported by truss rods, D, the ends of the rods being screwed or fastened into the chains.

For the purpose of reducing the car to the smallest space, it is made the width of a seat for two persons, the seat being placed across the car, and doors on the sides of the car for each seat, thus af-

fording easy facility for egress and ingress. The lower cars are suspended from the lower tracks, the wheels being attached to the top of the car; the upper cars run upon the rails as upon other railways. All the cars are propelled by a succession of endless ropes, E, which are sustained at intervals by grooved wheels, F, that are fastened to the lower edge of the arm. The ropes will run the distance of two squares, or a greater distance, if found practicable.

The engines for propelling the ropes are placed under the sidewalk or in the cellars, putting in motion a vertical shaft, G, to which the rope-propelling machinery is attached; this machinery is simple, being two spur wheels, H, above two grooved ones that grasp the rope, so arranged by levers that the grooved wheels tighten upon the

rope in proportion to the weight drawn. Each engine will propel two ropes; if the ropes extend 800 feet, the engines will be placed four squares apart.

The machinery for attaching the car to the rope is also simple, and so arranged as to prevent any shock at the starting of the car; the rope is permitted to slip until the car has attained the momentum of the rope. When started, the car will proceed to the end of the railway without stopping, or requiring the attention of any one, acting automatically—releasing its hold upon one rope, seizing the next in succession unless it is stopped at the stations, being entirely under the control of the person who attends to the stopping and starting of the cars. It is proposed, instead of sending conductors with the cars, to have two persons at each station—one to stop and start the cars, the other to receive tickets; if it is found necessary, a conductor may be sent with each car, who can stop or start it at pleasure by pulling or releasing a cord pendant from the top of the car.

Such is the construction of the railway that the cars cannot be run off the tracks; they are removed from one track to the other, at the ends of the road, by a sliding table, and in the same way may be removed at intermediate points, from track to track, or taken from the tracks, when necessary, and placed in depots.

The streets are crossed by suspending the frames that support the tracks in the manner of a suspension bridge. Should it be deemed preferable, the whole railway can be built in this way, and present a light and beautiful appearance; but should it be built supported by pillars, except at the crossing of the streets—as shown in the engraving—it would be, if properly and tastefully constructed, ornamental instead of unsightly, occupying but little space, and in no way obstructing the light, or darkening the lower storeys of the houses.

THE ROYAL CORNWALL POLYTECHNIC SOCIETY.

The care and deliberation required in awarding prizes and giving decisions concerning the various artistic and mechanical productions exhibited at the Royal Cornwall Polytechnic Society's late Exhibition at Falmouth have necessitated some delay in the issue of the list of awards. Among the official list we find the following:—

GALE'S METHOD OF PROTECTING GUNPOWDER.—The judges highly approve of Mr. Gale's method of protecting gunpowder, and consider that if any means could be adopted to avoid so great an increase of bulk, it would become of great national importance, and an invention that would unquestionably effect a great saving of life and property. The mixing and sifting is effected so easily that the judges consider it would not materially operate against its general use. They award it the first bronze medal.

PRENTICE'S GUN COTTON.—With reference to Prentice's Gun Cotton, the judges think it right to mention that the experiments were tried under a disadvantage, from the fact that the holes were all of too great diameter for the specimens charged brought by the agent. The experiments were, however, considered satisfactory, and the powder of the cotton was thought to be quite equal to that of ordinary powder; and as it possesses also the advantage of being almost smokeless, the judges consider it deserving of a high testimonial from the society. Regarding it as a valuable application of an old invention to mining purposes, they award it the first bronze medal.

NOBEL'S NITRO-GLYCERINE.—The judges consider Mr. Nobel's Nitro-Glycerine a very valuable explosive agent, possessing enormous power, and, in addition, the great advantage of not exploding except when confined. The small space which it occupies, in proportion to its power, renders it necessary to drive only one hole for the removal of immense masses of rock, thereby effecting a great saving of labour. As far as they can judge, the increase of power, as compared with ordinary gunpowder, will enable it to be used at as small a cost. The judges saw a wrought-iron anvil, of about 3 cwt., blown to pieces with a charge of less than 1 ounce in a $\frac{1}{4}$ -inch hole, and with a charge of 4 lbs from 40 to 50 tons of rock was completely scattered, and the surrounding rock rent in all directions. It was computed that had the hole been less in diameter, the same effect would have been produced with a much smaller charge. They have much pleasure in awarding a first silver medal.

ONE-THIRD of the coal used in France is imported from England, Belgium, and Prussia.

ANSWERS TO CORRESPONDENTS.

Our correspondents will observe the pruning knife is often used on their communications: will they kindly spare us the trouble!

INVENTOR.—If your invention can do all you say it is capable of doing, it is indeed a great one. But how to advise you in the matter we know not. There is no association of the kind you note, and were any such advertised we would think twice before we trusted it. Willingly would we send you instructions, did we know how: failing that, if you look at the matter in a mere monetary light, keep your invention till better days come. You might advertise for some one willing to assist you, or endeavour to get acquainted with a speculative manufacturer. Such, in several instances, have taken up inventions, and carried them through, to the profit of all concerned.

APPRENTICE.—"Practical Illustrations of Land and Marine Engines," by N. P. Burgh, £2 2s.; Spon, Bucklersbury; "Rules for Designing, Constructing, and Erecting Land and Marine Engines and Boilers," 4s. 6d., same author and publisher; "Engineering Drawing" (Armengaud and Le Blanc), 35s.; Spon; then there are Blunt and Stephenson's work, Clark on the Locomotive, and others. Send to Spon's, 16, Bucklersbury, and they will return you their excellent and valuable catalogue, which see further; and keep it by you also to show your friends. We wish you well, and hope to hear of you as a first-class mechanic. Remember the school rhyme, beginning, "If at first you don't succeed."

A. F. T. (Grahamston).—Of the two we prefer the former arrangement, which has the additional value of being ship-shape. We are glad you overhauled Mr. Woodcroft's volumes, for you will have satisfied yourself as to the originality of your scheme; with which, should you proceed, claim also the second working. If you do not intend to patent, we will be happy to illustrate the idea from your present sketch, you sending us a description of the other. We think you should persevere.

MODEL ENIGMA.—Consult a cheap work on the engine; such as have been advertised in our columns.

R. H. U.—Thanks. The inquiry has been answered privately by a correspondent.

INQUIRY.—Will endeavour to supply the information. There was nothing of the madman about him.

W. SPARKS.—See back numbers.

BEN JONSON.—Five per cent., or a lump sum over 15 years at a certain estimated sale. It greatly depends on demand.

J. HICKMAN.—A stamp carries the Guide. Concerning the straight-edge, write to the advertiser.

H. LE NOIR.—Get Spon's catalogue, and select from a number there.

PETRO.—Vol. IV., Holtzapffel's work has various arrangements in it. See "Notes and Queries."

J. M. W.—Answered by another.

WOMAN-AS B. SC.—Send to secretary at the University. He will be happy to send you the information.

C. E. Southwell.—Many thanks. You will think with us, there is no gain in pursuing the matter further.

H. BROWN.—You can procure them by order, through any bookseller. The method was illustrated in previous numbers. There is no offence.

DAVIS.—Send to Mr. Parker, engineer, Lilford-road, Cambridge.

C. J. C.—A paper was read before the British Association on the subject, which, among others, will be published by Robert Hardwicke, 192, Piccadilly; write to them, asking if it will be illustrated. The Engineer of Sept. 22 has "Modifications and Improvements in the Injector," (illustrated)—it may suit your purpose; it is by the author of the aforesaid paper. To your second query: order of Spon, Weale, or Lockwood.

MACHINA VI VAPORIS.—You won't get it done for less. See "Notes and Queries."

POSTULATA.—All about it in chap. 3, vol. 1st, Holtzapffel's work by Spon, Bucklersbury.

. We have to ask our correspondents to so sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them by the thousand; the same with "Well-Wisher," &c. If they don't like to see their own names paraded, use those of an ancient or any other man.

Several letters remain over till next week for answer. Letters applying for information to be furnished by post cannot be attended to.

Correspondents are requested to keep copies of their drawings and manuscripts, as the Editor cannot undertake to return such as may be rejected.

ANGLO-FRENCH ENGINEERING COMPETITION.—The Graffenstaden Works, in Alsace, have obtained the contract for 22 out of the 46 locomotives for which the Baden Government recently invited tenders, the remaining 24 being taken by local Baden manufacturers. The respective prices demanded were—by the French manufacturers, £1,800; by the Badenese, £2,228 16s.; and by the English, £2,828 16s. each.

ATLANTIC CABLE.—It is proposed that on the next attempt to lay an Atlantic cable two separate ones should be used. The shore ends being secured at Valencia and Newfoundland, the cables may be paid out simultaneously; when arriving at a certain point a splice may be made and the entire cable committed to the deep. Had this course been adopted the late fatal disaster would have been avoided.—*Notes and Queries.*

THE ENGLISH MECHANIC!

NEXT WEEK will be published the FIRST VOLUME

of
THE ENGLISH MECHANIC.
A Record of Mechanical Invention, Scientific, and Industrial Progress.

UPWARDS OF ONE HUNDRED ILLUSTRATIONS.

Handsomely bound, gilt edges, 4s. 6d.; post free, 5s.
GEORGE MADDICK, 162, FLEET-STREET, LONDON, and all Booksellers.

THE ENGLISH MECHANIC.

Every Tuesday, One Penny. Monthly Parts, 5d.
This day (No. 26) completes the First Volume.
. Title Page and Index, One Penny. Cases for binding, One Shilling and Sixpence.

It is solicited that all back Numbers be ordered at once.

All the early Numbers have been reprinted. It is therefore necessary that sets be made up at once, as there will be no further reprints owing to the great expense they entail.

162, FLEET-STREET, LONDON, and all Booksellers.

TO ADVERTISERS AND CORRESPONDENTS.

. In future all Advertisements and Communications for the Editor to be sent to
162, FLEET-STREET.

OUR MONTHLY PARTS.

Part 5 of THE ENGLISH MECHANIC, in coloured wrapper, is now ready.

Price 6d. only! Post free, 7d.

All back Nos. have been reprinted, and can be had direct from our Office, or through any bookseller.

TO ADVERTISERS.

As the ENGLISH MECHANIC addresses itself to the largest and most intelligent portion of the community, and is the only Paper of the kind established, it offers unusual advantages as an advertising medium.

SCALE FOR ADVERTISEMENTS:

One column	3	0 0

Post-Office Orders to be made payable to GEORGE MADDICK, Fleet Street Branch.

All Advertisements should be sent to us not later than Friday.

The English Mechanic.

FRIDAY, OCTOBER 6TH, 1865.

WORK IN THE FACTORY.

THE fourth report of the Factory Commissioners, as they are termed, has been published, and shocking indeed are the disclosures it makes concerning the state of things in some of our most important industries. It is the issuing of such reports that shows us how far back in civilization we still are, and the herculean task to be accomplished ere the healthy influence of Christianity—we may mention it as an element of success in a nation's growth—can be felt throughout our insular home. Debauchery, selfishness, ignorance, and its brood of degradations hold high carnival in the land; and we do not know whom to blame most, the masters who employ and pay no heed either to the moral or physical welfare of their workmen, or the workmen themselves. We learn yet again that a very old man is the Sheffield grinder at 42; and that he has lived a "tidy life" who struggles on to 36! The children, too, continue to be dreadfully neglected, according to the evidence given before the various reporters. One little fellow of 14 had been at work at cutlery half his life, and he in evidence said, "I don't know of London, or of Queen Victoria, or if she is a woman, or takes care of the country." Another one, asked concerning the Queen, said, "Have heard the name on it—can't tell what it means. She finds 'em money." Another poor little chap "thinks there are about 32 pennies to half-a-crown—that four times four is eight—that we have a king, (told it is a queen), they call her the Princess

Alexandra. (Told she is married to the Queen's son, the Queen's son is the Princess Alexandra; a princess is a man.) A boy aged 12, stated, "I don't know anything about the Queen or England. Don't live in England. Think it is a country, but didn't know before. There are six days in a week." And yet our missions to all parts of the world, excepting home, cost millions annually! It may be said this is not an engineering matter; perhaps not, but engineers and mechanics in general are men, and it is to men we speak.

Referring to the grinders, the Commissioners point out that the adoption of a mechanical contrivance called a "fan," would at very small expense be a great advantage. They consider, as do we, that the injurious effects of night-work upon the constitution, the habits, and morals of the young warrant a recommendation that legislation should prevent any person under the age of 18 being subjected to such labour at night. The operation of the Factory Act should be extended to these trades, and the law carried into effect, even in small shops and houses where such avocations are pursued. A like provision should be made in every trade, we care not what it may be, or where carried on. The tale from the seat of glass making, artificial flower making, needle making, and other trades in which female and youthful labour is required and used, is truly heart-rending, and cries aloud for help for the helpless. We who are so ready to cry shame when any act of an extra oppressive character is done in any other country, have reason to blush for ourselves. The population may be growing better as a whole, but we fancy much is left unrecorded through the super-refinement or laxity of the laws; certainly the reports from time to time issued like unto the one we are now noticing, tend to give the lie to the oft-repeated statement that we are growing better as a nation. For one, we don't believe anything of the kind; we believe that selfishness is more widespread now than ever it was in the history of the land, and that a cheap press is daily accumulating the facts in proof. Nor will this lamentable state of things be altered until men seek for the reception of good in bestowing it on others, that simple "doing as we would be done by," which yet seems so very hard a task. At all hazards the youth of both sexes must be protected from selfish rapacity, and we hope to see the recommendations of the Factory Commissioners carried out without a day's unnecessary delay.

ON THE APPLICATION OF SPECTRUM ANALYSIS TO MICROSCOPICAL INVESTIGATIONS.*

By H. C. SORBY, F.R.S.

(Concluded from page 8.)

Though in actual practice many other facts may turn up to render special modifications necessary, yet the following is the method I should adopt in examining a mark or stain supposed to be due to blood, assuming that only a small quantity was at my disposal. I should first cut off a portion of the material where not marked, and digest it in four or five drops of water in a watch-glass, squeezing it with forceps, and moistening it over and over again. If the solution became coloured, I should introduce it into a cell and determine the character of the spectrum, both in its natural state, and after having been acted on by the different reagents already mentioned. I should then add a very little blood to a few drops of water, and digest in that solution a small piece of the material, so as to make out whether it contained anything that acts on the colouring matter of blood. Having satisfied myself on these points, I should cut off a small bit of the stained portion, using from 1-10th to 1/4th of an inch square, according to the character of the mark, and the amount of material at my disposal, and digest it in three or four drops of water in a watch glass. If the solution became well coloured, I should not squeeze the material so much as to detach many minute particles of foreign matter; but if there appeared to be very little colour present, I should dissolve from it all I could, and take care to waste as little solution as possible, and have no more than would properly fill the cell. Transferring the solution to a cell about 1/2 inch long and 1/4 inch in diameter, and having placed it horizontally in front of the slit, and left it a short time, so that the minute particles of foreign matter might settle to the lower side of the tube, I should examine the spectrum, and carefully note the exact position and general characters of the absorption-bands. If the solution were too strong, diluting it until they were well seen. If the spectrum were like No. 2, I should feel nearly sure that the mark was due to blood; and, if it had

been kept dry in a town, I should also conclude that it was nearly fresh. If it were as No. 4, I should feel inclined to believe that it had been exposed to the air for some time; but, unfortunately, the character of the atmosphere makes so much difference that no rule can be given. If, however, in any particular instance a knowledge of the length of time that had elapsed since the blood was fresh were of importance, a more definite opinion might be formed after a few days' experiment with fresh blood, keeping it, if possible, under the same conditions, and using the same material as in the case in question. If the spectrum obtained was like No. 4, I should add ammonia in excess, so as to obtain one like No. 5, and afterwards add citric acid in excess, so as to see spectrum No. 7. Then adding excess of ammonia and a small quantity of protosulphate of iron, stirring it to dissolve all the oxide, but not so much as to peroxidize and make the solution so yellow that it would not transmit the green, the spectrum No. 8 would be well seen, even when a very small quantity of blood had been present. If plenty of material remained, I should take another portion, dissolve the blood from it, add citrate of ammonia, taking great care that the solution was never acid, and then deoxidize by means of a little protosulphate of iron, so as to obtain No. 6; and I should also mount a dry specimen on glass, to keep as a permanent proof. If all the characteristic results followed, I think no one could hesitate in giving evidence that the mark was blood; though, of course, these facts alone would not decide whether or not it was human—if possible, that must be accomplished by other means, or a conclusion formed from other considerations.

If the quantity dissolved out at first gave a very faint spectrum, it would be well not to attempt to see the spectra Nos. 5, 6, and 7, but to act on the solution with citric acid, filtering, if requisite, and then to add ammonia and protosulphate of iron, so as to obtain No. 8. The material itself might also have so acted on the blood that no other spectrum could be seen. It is, however, so characteristic, that, even then, one could scarcely hesitate in deciding that the stain was due to blood.

If the material had evidently been washed, so that no spectrum could be obtained from a simple solution, having first ascertained what effect citric acid has on the dye, I should digest a stained portion in a solution of 1/4rd or 1/5th of a grain of citric acid in a few drops of water, so as not to have more liquid than will fill the cell. filter, if requisite, add excess of ammonia, and then protosulphate of iron. Unless very thoroughly washed out whilst the blood was quite fresh, no mere washing with hot or cold water without brushing or other mechanical means being adopted to dislodge the minute insoluble particles, will so completely remove the stain that it could not be detected in this manner; except, indeed, any of those foreign substances be present which precipitate the colouring-matter in a form insoluble in citric acid and ammonia.

Supposing a clear coloured solution be obtained, which gives a different spectrum or set of spectra to those characteristic of blood, it might be desirable to ascertain the nature of the substance to which they were really due. I have already described the spectra of a few colouring-matters, but in all cases I strongly recommend the study of the spectra of any substances likely to occur in any particular instance. Even if blood has been detected, this would also be desirable, since an opinion could then be given with more confidence.

My conclusion is that, even in cases where the usual tests would fail, the detection of minute traces of blood need not in general be a weak point in the evidence of crime. Having proved it to be present, the question of its having been human or not must be decided by other considerations; and thus as a positive proof the evidence may be equivocal: but if a stain supposed to be due to blood, which, if it were, would certainly give the characteristic spectra, fail to do so, the negative evidence would be decisive.

It is, of course, at first, always difficult to know to what subjects a new form of apparatus may be usefully applied; but I trust that the facts I have described will suffice to prove that, for so simple an addition, the resources of the microscope as an instrument of research are greatly increased by our being able to use it also as a spectroscope.

We learn that Count Castracane, at Rome, has employed a monochromatic light for the microscope with excellent effect, and has found by experiment that greenish blue is the tint most favourable for observing extremely delicate organization—such as the *pleurosigma angulatum*; the lens required is of less power than when white light is employed.

LETTERS TO THE EDITOR

(We do not hold ourselves responsible for the opinions of our correspondents.)

Sir,—I observed a curious-looking contrivance on a steamboat on the Rhine. Each crank was in two parts, set at an angle of about 40° to each other, and connected by a thick strap or link of brass, with three slots in it; the links were about 6 or 8 inches long. Can any of your readers explain this? (The engines seemed to be high and low pressure.)

In reply to "William Taylor," I quote from Holtzapffel, page 1, 404, (using the pruning-knife here and there) Every coat of varnish or colour is dried by placing the object in a stove, heated by fires to a temperature as high as can safely be employed without injuring the articles, or causing the varnish to blister or run. The colours for ornamental works are ground in linseed oil or turpentine, and mixed with copal or animé varnish for working.

Metal works are cleaned with turpentine. Ivory black is mixed with dark animé varnish for the ground of black works, and three or four coats of japan are applied.

Can any of your readers tell me the price of a good, strong, plain side-rest for a 6 inch lathe for metal work.

C. SWERT.

South Lodge, Kilburn Priory, St. John's wood, N.W.

Sir,—I regret that Mr. Merritt should consider the two chucks so much alike that I was needlessly occupying your columns by sending the description I did.

If, however, as he thinks they are nearly identical, I can assure him that the one I sent is described in Holtzapffel's catalogue, 1853 item No. 1557.

THOMAS A. COTCHATT.

OUR SUBSCRIBERS' NOTES AND QUERIES.

TELEGRAPH BELL.—How can I construct a telegraph bell to be worked by a single wire from one house to another, and will the same wire do for return signals?—WM. JENKINS.

PATENT INDIA-RUBBER DECKLE STRAPS.—Is there a composition for, or method of, splicing these, or stopping them from cracking?—JOHN SUTTON (Paper-maker).

BESSEMER STEEL TOOLS.—Where can I get a best-tempered graving tool for cutting pearl? Does any one make and supply gravers made from Bessemer steel?—COMPOS.

BOILER PLATE.—What thickness of plate should I use for a boiler 4 feet by 1 foot, to bear a pressure of 80 lb. per square inch—and the rule?—R. E. MELLOR.

ECCENTRIC CHUCK.—How can I make such for amateur? How to adapt overhead motion to ordinary 6-inch iron bed lathe (for drilling and cutting grooves with cutters)?—PETO.

REUMKOPF COIL.—Will Mr. Parkinson give me size of bobbin for this coil?—J. JOHNSON. [No room to insert description if obtained. Send privately to the gentleman, Ed. E.M.]

CEMENT.—Wanted: a transparent cement for glass, such as used by opticians?—R. W.

STRENGTH OF ROPES.—Presuming the breaking strain of 4-inch rope to be 5½ tons, the same being used as a purchase with a double and treble block—there being six parts of the rope—what is the maximum weight?—W. P. GIBBS.

GAS PURIFIER.—How have I such a heavy pressure on mine? I have no exhauster. What is the best remedy?—VENTA.

PISTON HEAD.—What substance had I best employ in making a piston-head to act in a cylinder 1 inch in bore, so as to keep it perfectly fluid tight—the piston having to lift a weight of 8 lbs.—DELTA.

HARDENING SPRINGS.—How can I harden wagon springs?—H. SMITH.

ELECTRIC CLOCK.—Will "A. Watson" (Leeds) tell me, is there a book extant giving a full account of the clock he mentions?—W. T. W.

COLOURING FLUID.—The names of different substances forming different colours, when dissolved in spirits of wine, or prepared any other way, or such as used by calico printers—or the name and price of a book on the subject?—JOHN CLYD.

PAPER BAG MACHINERY.—Who is the maker of these machines? or, where are they to be had?—J. H. B.

BOILER.—What size of boiler is necessary to work an engine consisting of cylinder, 6 inch stroke, 2½ inch diameter, with top and bottom cap, piston, slide box, and valve? It is required to drive a foot lathe.—MACHINA VI VAPORIS.

ELECTROLOGY.—How can I electrotype steel or iron with copper, silver, or gold—the battery and power?—KNOWSTICK.

ECCENTRIC SHAFT.—How best to mark off an eccentric sheave—the angular line of advance, so it can be placed on the shaft in proper position at once? also, how to find the lap and lead of the slide valve?—ECCENTRIC.

SCREW.—How is the screw cut in the wheel of an eccentric chuck for a tangent to work in?—W. G. P.

MICROSCOPE.—How to construct a cheap and powerful microscope—giving glasses.—JAS. A. HARVEY.

LATHE CENTRES.

Sir,—In tool shops the centres are all turned to an angle of 90 degrees.

THOMAS JACKSON.

Sir,—The proper angles for the centres of an iron turning lathe are, for very large work, 60°; for general, do, 80°; and for light, 70°. On no condition have your centre over 90°.

WM. CHIDDEN.

Albion Works, Paisley.

* Extracted from the Quarterly Journal of Science.

Sir,—In answer to "Systematic," I believe 45° is the best angle for lathe centres.

"J. Patts" should try the recipe given by Mr. Babbage, viz. :—

Scratch a cross on one side of the glass; next fix a centre punch in a vice with the point upwards; then get some one to hold the glass, so that the point of the centre-punch touches the centre of the cross; take another centre punch, and hold it exactly over the point of the lower one; give it a smart blow, and a perfectly round hole will be the result.

CONE-PULLEY.

BOILER PRESSURE.

Sir,—In answer to "J. Soundie," in No. 25, he would have a pressure of 1½ pound per square inch, or a pressure of 9,720 on the entire surface of the boiler. The size of the tube making no difference, a ½ tube will exert the same pressure as a 3 inch tube.

R. E. MALLON.

FURNACE BARS.

Sir,—No one having answered "Steam Mills" question about furnace bars, I send a rough sketch of one I put in

3'-6"

about 3 years ago, and now to all appearance they are as good as when first cast; the current of air through them keeps them quite cool, and they may be made and used by anybody. The space between bars is. THOMAS JACKSON.

VARNISHING WOOD.

Sir,—In reply to "Diamond," I will endeavour to instruct him about wood before varnishing. Supposing it is deal for instance (or any other wood), he should first "stop" it with putty coloured to match wood; then rub off rough edges of stopping, and make some glue with strong size (2 lbs. of glue to one gallon of water); from which, after boiling, take some out into a paint pan, and let it get half cold—that is, until it begins to thicken; then apply it to the wood with a pound brush. Let the size get dry, and varnish with one or two coats. If sized twice, the glass will be richer. This is the plan I have used most successfully.

S. B.

WINTER'S ELECTRICAL MACHINE.

Sir,—In answer to "Round Head," I received a very clear description of Winter's electrical machine from Mr. Hart, having written to him privately asking him to communicate either through THE ENGLISH MECHANIC, or privately; he did the latter in a most obliging manner, and I have no doubt if he sees "Round Head's" letter he will get an answer. Should anything prevent, I shall be most happy to send a drawing and description.

F. T. PARKINSON.

Ashton Villa, St. Mark's, Cheltenham.

STEAM PORTS.

Sir,—If Mr. Jamieson arranges one cylinder to work with the ordinary slide valve, and the other with Worthington's steam valve, he will then have the steam on the same side of both pistons when one valve is up, and the other down. A glance at the enclosed sketch will shew the

FIG. 3.

FIG. 1.

FIG. 2.

section of the Worthington steam valve. Fig 1 is a view of the valve with one port open to steam, and the other to exhaust; fig 2 is the valve face; fig 3 the valve seat.

M. J.

MAKING PRINTER'S INKS.

Sir,—In answer to "Nemo," Leeds, the following may prove useful to him:—Grind the colours with printer's varnish and dryers to the thickness required. Any shade may be produced by mixing the following colours:—Red: to pale vermilion add carmine. Bright pale blue ultramarine, deep bronze blue, Chinese (?) To make black ink for printing, take linseed oil, and heat in a proper vessel till it begins to boil; then remove it from the fire, and kindle the vapour. Allow it to burn until it becomes stringy—then add gradually, to every quart, 1 lb. black resin (which dissolve and add cautiously), and 4 lbs. dry brown soap shavings. Set the mixture on the fire, and stir it until combination is complete. Next, put into a suitable vessel 1 oz. finely-ground indigo, 1 oz. fine Prussian blue, and 18 oz. fine lamp black for every pound of resin employed; pour the liquid on the colours, well mix, and then grind in a mill.

[We hope "Nemo" now understands the matter.—Ed. E.M.]

HOT WATER PIPES.

Sir,—In answer to "Ironmonger," in greenhouses, conservatories, and such like buildings, where the temperature is required to be kept at about 6½°, divide the cubic measure.

ment by 30, it will give the required quantity of pipes; if for forcing houses, where it is desirable to keep the temperature in the coldest weather at 70° to 75°, divide the cubic measurement by 30, to obtain the number of feet of 4 inch pipe, but if the pipes are to be 3 inches, add one third to this quantity; if 2 inch pipes are used, double the length of 4 inch pipes. As for boiler, I think he will find the saddle back the best.

[See also Weale's "Fundamental Treatise on Warming and Ventilating," 2s.]

SLAG FOR POLISHING.

Sir,—Iron slag, prepared as described in No. 26, has long been used in Scotland for polishing steel.

GAMMA.

DOUBLE PHOTOGRAPHS.

Sir,—Respecting the "Double Photograph."—The great secret is this, viz.:—That you expose one half only of your sensitised plate at once; which is readily accomplished by a moveable shutter, which any of your readers may easily construct from the accompanying diagram.

A, B, C, D, is a light wooden frame made to fit tightly inside the camera just in front of the dark slide. Inside this frame is a groove in which the wooden shutter, E, slides backwards and forwards from the side B, D, to the side A, C, or vice versa, thus alternately exposing the right and left hand side of the sensitised plate. Thus, when you have exposed the left hand side of your plate for a sifting picture, you remove your dark slide for a second, whilst you push the shutter E to the other side of the shutter-frame. Replace your dark slide, and take a standing, or any other picture, on the right hand side of your plate. Care must be taken to have the shutter extend exactly to the centre of the frame, and to have an immovable object, such as a table, &c., form the middle of the picture. The shutter must be blackened with a mixture of lamp-black and water to prevent reflection.

B. B. WAGO.

DISK CHUCK.

Sir,—I send you a slight sketch and a description of a "disk chuck," asked for by one of your correspondents.

A is a cup chuck having a screw H fixed in its centre, so that it will turn correctly in the lathe. B is a cone with a hole drilled through its centre, and made to fit the screw H, but so that it will slide along it, not screw. C is a small nut. D is a kind of cup which also slides along the screws H. E is a washer, and F is a nut.

To use the chuck:—Put on the disk K, slide up the cone B till it centres it truly, then lightly screw up the nut C, just sufficient to hold B in its place and no more.

Next, slide up the cap D till it presses against the disk K, put on the washer E, and screw up the nut F tightly. When you will find your work held firmly.

Mind the cone B has nothing to do with the holding the work, its duty being merely to fix it truly central.

AN AMATEUR TURNER.

COPPER WIRE.

Sir,—Your invaluable correspondent, "G. F. Williams," in the plenitude of his information, must be careful lest unwittingly he should mislead some of the innumerable

querists who make known their wants, &c., through the medium of your valuable journal.

I would respectfully ask "G. F. W." if he can furnish me with the diameter of the "No. 35" copper wire which measures about one mile to a pound (when covered with silk, I presume)? And if unable to do that, will he kindly inform me what gauge he uses to get at the number.—If the E. W. G., he is certainly in an error, as No. 35, according to the Birmingham gauge, will not measure 1,500 yards to the pound uncovered, and a pound covered with silk would be at least 100 yards less than that; nor do I know of any gauge in use at the present time which would give one mile (about) of No. 35, copper wire to the pound. A size finer, or No. 36, would not be a mile to the pound by a tolerable stretch.

If, however, your correspondent's friend, Mr. S. Somers, Salford, can furnish good copper wire well covered with silk measuring about one mile to the pound, (no matter what number he calls it, the length is the test, and that is regulated by the diameter) his covering apparatus need never be idle, if he can supply it at 12s. 6d. per lb., since there are large consumers in London who would take it by the cwt. at such a price.

The fact of the matter is, a pound of copper wire of high conductivity drawn to measure one mile, together with the silk requisite for covering it efficiently would cost more than the money, consequently the tedious and very nice, and I may say delicate process of covering, and winding so fine a wire would have to be done for nothing; and the covering of such wire, I may add, is a process requiring very nicely adjusted and expensive machinery.

S. TAYLOR.

A SIMPLE FURNACE.

Sir,—In reply to "Amateur Mechanic," I call his attention to the following simple furnace, which will cost him little or nothing to construct. I describe it for the benefit of all English mechanics, readers of your invaluable journal. Procure two sound flower pots, one about 12 in. high, the other 9; the larger one should have holes along the side near the bottom in addition to the one in the centre of the bottom; one of these will do for the blast hole. The hole in the bottom, of each must be carefully knocked out to a circle of 4 inches diameter. Proceed to bind them round with iron wire, as they will crack with the heat, then choose the place in which you purpose placing the furnace, and lay two bricks parallel to each other four inches apart; on these place the larger pot, and put the smaller one on it, keeping them about an inch apart with sand rammed tight. To prevent the same running out at the bottom, make a ring of tin with a hole for the blast. Some short pieces of thick iron wire will do for the furnace's fire bars; now bank the furnace well up with earth, and it will be complete. Coke and charcoal mixed is the best fuel, but if not to hand coal will do. When the fire has burnt brightly place the crucible in it and cover it with coke or coal. Ten minutes blowing with the kitchen bellows will melt brass. I append diagrams:—

A, ash-pit; B, hole for blast; C and D, flower-pots; E, E, earth banked up.

A, ash-pit; B, air-chamber; C, C, C, C, sand between pots; D, body of furnace; E, E, blast pipe; G, bellows; H, fire bars.

EDWARD MCGURK.

WATER AND SPIRIT GAUGE REGULATORS.

Sir,—The water gauge regulator mentioned by "Underbands" may be made as follows.—Obtain a piece of glass tubing say ¾" diam. x 6" long, cement on the two ends brass caps; a small hole should be perforated in one of these caps, in order to allow a thin rod or bar of metal to slide backwards and forwards within the glass cylinder, so as to form contact between the two capped ends when necessary. Next fill with water and attach the two capped ends respectively to the two ends of secondary wire. This instrument acts as a second channel, or shunt for the current to travel. By withdrawing the bar from the glass tube the shock is increased, when pressed in diminished, because when pressed in the shunt is shortened and less resistant than the human body, allowing a greater proportion of current to pass by this channel, thus lessening or leaving a smaller portion available for giving shocks.

A decomposition of the water in the glass tube will gradually take place, causing bubbles of gas to be liberated, consequently the water should be replenished occasionally for this purpose one of the brass caps should be made to unscrew when required.

Spirit regulators are often used for the purpose indicated by "Underbands." In their construction they are essential

the same as the one I have described, with this difference, the tube is filled with spirits of wine, and one end attached to one of the secondary wire and the other to the party undergoing the shock.

The action of this kind of regulator is the reverse of that of the water gauge. Spirits of wine, it is well known, offers an immense resistance to the passage of a current of electricity; the shock is therefore in this case reduced by withdrawing the bar, causing the current to pass through a greater portion of the resisting fluid, thus weakening it before arriving at the party receiving the shock, and by the same reasoning the shock is increased by pressing the bar in.

Earthenware pots can be purchased for a very few pence, at almost any electrical instrument maker; the name of several have been given in previous numbers.

EDWIN FURZE.

PLATINUM BRONZE.

Sir,—After failing (in a large city) to get platinum bronze, I dissolved platinum wire in nitromuriatic acid, heating and evaporating to dryness, getting an orange residue. On adding water to this, a deep yellow solution resulted; brushing clean brass with it, as "Electra" directs, some parts were jet, some grey, and, by the time the moisture had gone off, so also had both black and grey. There was a clean coat of platinum left only. I tried it with and without heat, washing, &c., with no better result.

By any friend pointing out faults in my manipulation will much oblige

GAMMA.

AMMONIA ENGINE.

Sir,—On referring to No. 26 of THE ENGLISH MECHANIC, I see that your correspondent, Edward Payne, wishes for further information concerning Teller's ammonia engine.

I am informed by a gentleman who has recently returned from the Continent that the invention mentioned in No. 1 of THE ENGLISH MECHANIC has been abandoned, and has so far proved a failure; but so far from the idea of using ammoniacal gas as a motive power being an impossibility, I am glad to inform you that in the course of a few days we shall have brought before the public an ammonia engine which has recently been patented in this country, and also on the continent, of which a model was shown at work to several witnesses in May, 1864, and had been explained to several gentlemen in the Feb. of the same year (which is previous to Mr. Teller's invention), and which I have no doubt will prove a powerful rival to steam.

If Edward Payne will be good enough to forward his address to M. Van Waegenbergh, 18, East Parade, Newcastle-on-Tyne, who is the original inventor of the ammonia engine, he will receive full information on the subject, which I have no doubt will prove of interest to him as well as to many others.

N. H.

LATHE CENTRES.

Sir,—For the information supplied to me by your kind correspondent, J. M., respecting Lathe Centres, I certainly feel greatly obliged to him. If some of your correspondents, perhaps, J. M., could inform me how to fix and turn on a lathe, the journals of a crank shaft, it would oblige. It is of cast-iron, there are three journals one on each side of the shaft, and the other on the crank, the radius of the crank is 1 ft. 6 in. The length of the shaft is about 8 feet.

SYSTEMATIC.

J. SOUNDLE'S QUESTION.

Sir,—Your correspondent, "J. Soundle," must have been somewhat perplexed at having two such different answers to his query, as appeared in No. 27, from "J. Newton" and "X. Y. Z." but, notwithstanding the discrepancy existing between their two calculations, both of them are right. The blunder originated in the vagueness of "J. Soundle's" question. He does not say whether his 24-feet tube is square or cylindrical. "J. Newton" assumes it to be the former, and "X. Y. Z." the latter—hence the discrepancy.

Your compositor has also omitted to place the decimal point before the figures "841" in X. Y. Z.'s letter, which would mislead any one not acquainted with the weight of water.

W. G. W.

DRILLING GLASS.

Sir,—The best and safest method of drilling glass is to use a brooch. No spear-pointed drill can be tempered hard enough not to break. The brooch can either be used as a drill with a bow, or by the hand. It should be selected of such a bore that it will make a hole of the required size, at about one inch from the end. It should be broken off sharp with a pair of pliers, at about an inch and a half, and when the sharp edges are blunted by drilling a fresh end should be made by breaking off an eighth of an inch, and so on, until the hole is bored. It is always desirable to drill from both sides, as it prevents the glass from breaking; drill lightly. Fine emery and oil, I think a better lubricator than turps.

TIMOTHY TWIST.

PERPETUAL MOTION.

We have received some dozen letters on perpetual motion, to which we cannot give space; we have room only for what can be of value to our readers.

FURNACE BARS.

"Steam Mills" to "J. B."—Please address, H. Pritchard, Lower Regent-street, Hinkley.

A PROSPECTUS has been issued by the committee of the Manchester District Art Workmen's Association, announcing that it is their intention to hold an exhibition of arts and manufactures early next year.

THE MATERIAL IN IRON SHIPS.*

By Messrs. T. TATE and W. FAIRBAIRN.

A paper, jointly contributed by these gentlemen on "The strength of material considered in relation to the construction of iron ships," excited considerable attention. It was of a highly technical character, but its conclusions are of considerable importance. In the paper the quality of iron was estimated by the work expended in the ultimate elongation of a bar one foot long and one square inch in section. This work or dynamic effect, gave a comparative measure of the powers of resistance of different kinds of material to a strain of the nature of impact. The values of this modulus or co-efficient of dynamic resistance, determined by Dr. Fairbairn's experiments for different plates or bars of iron, showed that the resistance of thick plates to rupture was about $2\frac{1}{2}$ times that of thin plates, that the resistance of thick plates are about one-tenth greater than that of the Low Moor iron plates A, and that the resistance of these latter plates was one-half greater than that of the rolled plates D. Similarly the work expended in the deflection of a bar, supported at its extremities by a force applied to its centre, might be taken as the modulus of dynamic resistance to a force of impact tending to produce transverse rupture. The next section of the paper gave the maximum transverse strain produced on a ship when the load was unequally distributed. The point of maximum strain was not always at the centre of the ship, as many practical men assumed. The third section of the paper gave the value of the moment of inertia for different elementary sections of material. Section four gave a certain simple general analytical expression for the moment of inertia of complex sections of girders, such as that of an iron ship. The distribution of the material, so that the beam might have the greatest strength, was next investigated; and the formula applied to the section of one of our most approved iron ships showed that the upper portion of the ship should be about one-half stronger than it was in order to have a proper distribution of the material. Section five treated of the penetration of iron armour-plates by flat-faced tempered steel shot. The following formula, derived from Dr. Fairbairn's experiments upon punching, was given. The work requisite to penetrate a plate varied as the square of its thickness, multiplied by the radius of the shot, or $V = C r t^2$. The constant of this formula, deduced from the experiments with ordnance, might be taken as 24400. It was shown from this formula that a 100lb. steel shot, five inches diameter, with a velocity of 1,200 feet per second, would completely perforate an armour plate exceeding five inches in thickness.

ON THE CAUSE OF THE VIOLENCE OCCASIONALLY ATTENDING THE EXPLOSION OF STEAM-BOILERS.

(Concluded from page 3.)

As a visible force steam cannot be said to exist. It is the name only for an effect produced in certain atmospheres by the operation of heat. In other words, steam is water and heat together—simply water and heat. If this heat could be conveyed as effectually into the same situation by any other means, the same results might be expected to follow, viz., the expansion of air into force or pressure. The brothers Montgolfier inflated a large balloon simply by altering the nature of the atmospheres within by the application of heat, and a force was attained which lifted themselves and their huge apparatus up to a great elevation.

The force which resulted in this case was probably greater than could have been obtained from steam machinery, as in all attempts to accomplish aerial navigation by the force of steam the weight has exceeded the power. So that it is apparent that great mechanical results may be attained by a trifling variation of the specific gravities of bodies, and that this may lead to results which cannot be arrived at by the employment of absolute forces developed by other means.

It is worthy of being borne in mind that water cannot be decomposed by heat. At all the stages of evaporation through which it passes it is normally present and has assumed no new qualities whatever. Many other bodies besides water possess the property of undergoing an entire change in appearance without losing any of their original qualities or assuming new ones. Resin, for instance, in its natural state or ground down into powder is different only in the singular variation of colour which results upon its being reduced from one state to the other. This is the case also with glass

* Read in Mechanical Section, British Association.

and several other bodies. Each of these substances may be made to resume their natural features by a process of reconversion effected by heat. In their usual state they have an approximate smoothness and solidity, and when pulverized they resemble one another more closely in opacity and colour. But the most important illustration perhaps of this parting with, and re-assumption of the natural properties of bodies is that exemplified in the conversion of water into steam, and the reconversion of steam into water. Whatever may be the nature of the change caused in a mass of water by its absorption of heat or the passage of heat through it escaping at its surface in the form of bubbles, it is held to be impracticable to reduce steam to water again without the absence of heat. Now it is commonly known that a quantity of water placed under the receiver of an air pump will, as the exhaust is carried on, appear to evaporate with great violence. The resemblance to the phenomena observed in the generation of steam is in this case very marked and singular. The water will appear to have become condensed on the inner surfaces of the dome, and the vessel containing the water may be entirely emptied by continuing the process. The influence of heat in producing steam is scarcely yet rendered sufficiently intelligible to lead to any opinion more reasonable than that it must be taken away to re-establish those conditions which it had apparently changed. The tendency of heat applied to the bottom of a boiler containing water is to pass through the metal and the mass of water, and out again through the upper surface of the metal into the air. It is curious that the manner in which heat should be conveyed through water is in the form of cellular spheres. Certain particles of water cohere so firmly round an increment of heat and in such order that they effectually prevent its assuming any other form but a spherical one, and this minute ascending globe presenting arches on all sides to the pressures by which it is encompassed rises unhurt through a mass of any quantity. Similar results may be witnessed in cellular globes formed without heat, some of which although presenting a large area to the pressure of the atmosphere, and being only 1-10,000th of an inch in thickness, retain the form of a globe until their contents become decomposed and eventually decompose the substance of which the spheres themselves are formed.

It could be fairly assumed that if any force expanding equally, and in all directions from a point, could be introduced within one of these spheres, unless the elements of the force were liable to decompose the medium within which the expansion occurred, would always retain the form of a globe; but, as a proof of the variable expansion of steam, it may be remarked that heat begins to ascend through water in forms representing the sections of a cone. It is not uncommon to observe innumerable bubbles floating about on the surface of boiling water, some of which retain their shape for several seconds, during which time they have a motion through space of twenty or thirty times their diameters. The cause of this motion is very singular, because it proves that at times heat can disturb a great quantity or weight of water by the simple act of rising through it—whereas, it is commonly supposed that its levity is so great, that it would have no more effect upon the water than a balloon would have upon the atmosphere in ascending through it. When these globules of heat explode, the heat they had contained becomes diffused over a larger area, by taking up new situations in the smaller interstices, between the gases which are above the water line in the boiler. In proportion, as the temperature of the steam space increases, the gases expand, and the interstices between them become diminished in size. Thus the heat is gradually forced within limits which continue to grow less and less until such forces of compression and resistance are reached between it and the water and material of the boiler, that the generation of more steam must be arrested, or the boiler must necessarily give way. When it is considered how great the difference would be in the size of a globule of heat when bound by and liberated from the pressure of the mass through which it has to ascend to become operative as force, it is rather astonishing that a greater number of boiler explosions do not occur.

Yet, probably, there are not many cases where the force of the steam, at the moment of an explosion, has ever nearly approached the measure of the resistance of the boiler, and, as already observed, it is not where the steam has reached any unusual pressure that we are to look for the necessary explosion of boilers. Mr. D. R. Clark, a gentleman who appears to have given some attention to the subject of boiler explosion, stated a few years since when the subject was inviting very serious attention, that the percussive force of the

steam suddenly disengaged from the heated water in a boiler acting against the material of the boiler, could not be adduced in explanation, and as the cause of the peculiar violence of the result of the explosion. Mr. Clark considered that the sudden dispersion and projection of the water in the boiler against the boundary surfaces of the boiler was the cause of this violence, the dispersion being caused by the momentary generation of steam throughout the mass of the water, and its efforts to escape. It was alleged by the same writer that the steam carried the water before it, and that the combined momentum of the steam and the water carried them like shot through and amongst the bounding surfaces, and deformed or shattered them in a manner not to be accounted for by single overpressure, or by simple momentum of steam. This forms one of the more ingenious but illlogical explanations offered concerning violent boiler explosions. Whoever has witnessed the ascension of heat through water must have noticed that it is absolutely impossible for a single globule of heat to leave the water line. Nothing but the heat is suffered to get free, and this carries only increase of temperature to the steam space. Moreover, a spherical body can never impart velocity to a liquid. A shot discharged vertically into a vessel containing water will flatten, and in sinking cause a rise at the circumference of the vessel in proportion to the quantity of water it has displaced, whereas if it were true that heat or steam could project water against the inner surfaces of a boiler, the shot should carry a column of water through the vessel that held it. It is probably more obvious that a body not capable of holding water upon its surface cannot project it with force, but rather pushes through it, and suffers the water to subside about it. Thus this cannot reasonably be alleged as a sufficient cause for the occasional violence of the explosion of boilers. But supposing that in the generation of steam the decomposition of water proceeds so far that one of its constituent gases is disengaged, and the other retained, we then reach conditions favourable to this violence. It would perhaps be well worthy of experiment to ascertain how far some preparation capable of rapidly absorbing oxygen would not prevent boiler incrustations, because oxygen is so dense that it may be poured from one vessel to another in the open air, while hydrogen will cause a weighted balloon to ascend. It is probably therefore that they do not operate together in what is called steam power, but that the lighter gas only is set free. If heated hydrogen be brought in contact with air an explosion is inevitable, and this fact may go some way to towards accounting for incipient combustion. If it be admitted also that gases may pass through the material of a boiler it will be then seen that the conditions of explosion are imminent, and only await some electrical motion to set them in force. This is given by the starting of the engine which exhausts the steam space of the boiler, and suffers the air to enter when an explosion results. It would not be devoid of interest to discover if a boiler exploding in this way would give off a momentary flash of light because boiler explosion may represent on a small scale some of the more wonderful phenomena of nature. Thunder follows lightning and precedes a fall of rain, and in boiler explosions we have water producing thunder, and perhaps unseen lightning.

F. M.

AEROSTATIC MACHINE.—M. Couturier, through the agency of Mr. Brooman, of Fleet-street, has introduced to notice what he designates "An improved Aerostatic Machine." It may be used for travelling through the air, or as a toy. It is composed of a hollow body, with extending arms concave below, and with a horizontal tail concave above. It carries a screw when used as a toy. When used for travelling through the air, the body is in the form of a basket for containing the aeronaut; the arms are fixed for a distance from the body and terminate in wings or flappers. Springs are fitted at the connection of the wings and arms, and by means of cords the aeronaut works the flappers, "and may even progress against the wind." When as a toy, the body is in the shape of a bird, and the arms and wings are fixtures; and extending upwards from the body is a rod, which carries a screw movable upon the rod; the air causes the rotation of the screw and carries along the toy. We are not aware that M. Couturier has ventured out in his basket to work the flappers—when he does, our readers will be informed.

The refuse of horn used in the manufacture of combs is used in the manufacture of prussiate of potash, and from the waste in this process is obtained the delicate pine apple flavour used by confectioners.

IMPROVEMENTS IN CARRIAGE WHEELS AND AXLES.

This invention of Benjamin Glover, of Parker-row, Dockhead, has for its object improvements in the formation of the boss of the wheel in combination with improvements in the construction of the end of the axle, for the purpose of securing the wheels thereon.

In Plate V., fig. 1 shows a vertical section of the boss *a*, of a wheel mounted upon one end of an axle *b*, the parts being constructed and arranged in accordance with the improvements; fig. 2 shows one end of the axle or arm *b*, separately; fig. 3 shows an end view of the axle *b*, with the ring or "collet" *c*, thereon; fig. 4 shows the ring or collet *c*, detached; and figs. 5 and 7 show separate views of the locking plate *d*. The end of the axle *b*, has a circular groove *b'*, formed thereon, other grooves or key-ways *b₂*, being formed at right angles thereto, so as to leave projections *b₃*, *b₄*, at the end of the arm *b*. The central opening in the ring or collet *c*, corresponds in form with the end of the axle, so that it can be easily slidden upon it; and when it has passed beyond the projections *b₃*, it can be turned round, so as to place the internal projections *c*, behind the projections *b₃*, the grooves or recesses *b₂*, and *c₂*, being thus brought opposite to each other into a position to receive the projections *d'*, which form part of the locking plate *d*. The several parts so

GLOVER'S WHEELS & AXLES.

put together are secured by the central screw pin *e*, being screwed into the end of the axle *b*, the shoulder formed by the collet *c*, serving to retain the wheel securely upon the axle, which is covered by the screw cap *f* screwed into the recesses formed on the outer side of the boss *a*. Oil, for lubricating the axle, is introduced when required, through the orifice *g*, which at other times is closed by a screw or plug.

The patentee remarks, that in the construction of wheels, according to this invention, for all kinds of road vehicles, no portion of the nave or stock projects beyond the line of the tyre, as is the case in ordinary wheels to the extent of from three inches, and in many cases considerably beyond, frequently causing collisions in passing other vehicles, and rendering wide vehicles almost useless for narrow streets and gate-ways. The ordinary mode of securing the wheel upon the axle by means of a collet or nut and linch pin involves the necessity of having a projecting nave, whereas by these improvements the wheel is secured to the arm by the collet *c*, and locking plate *d*, (without the aid of linch pins), thus greatly reducing the width of the parts, and rendering the projection of the nave beyond the line of the tyre of the wheel unnecessary.

The claim is "for the improved mode of constructing and combining the parts of carriage wheels and their axles, for the purpose of securing the wheels upon the ends of the axles or arms, as described."

M. JULES GINDBRE reports, in *Les Mondes*, that he has prepared and patented a new manure—a combination of potash and feldspar—which is suitable for all kinds of culture, especially for the vine, and which has been tried with good effect near Bordeaux.

DEEP SEA CABLES, &c.

At the British Association Congress a paper was read on the Sheathing of Deep Sea Cables, by Mr. C. W. Siemens. The paper called attention to the forces which act upon a cable while descending to the bottom, and to certain conditions which have to be fulfilled in order to insure its durability when laid. It was maintained that the spiral, or rather helical, sheathing usually applied to deep sea cables is defective, because it must necessarily elongate and twist round its own axis during its descent, because the iron or steel wires composing the sheathing frequently break and endanger the success of the operation, and because such cables when laid are rapidly destroyed through oxidation of the iron. It was shown that an outer covering of each wire with hemp, while beneficial in reducing the specific gravity of an iron-covered cable, cannot be depended upon for strength, and rather increases the risk of rapid destruction of the cable when laid. The paper proceeded to show that a sheathing composed of two layers of strong hemp under a certain tension bound tightly round by a flexible armour of copper or zinc sheathing is free from the objections previously enumerated, that such a cable actually forms the connecting link between France and Algeria, and has given evidence of permanent success.

Mr. William Hooper read a paper in the same section "On the Applicability of India-rubber as an Insulator for Telegraphic Conductors." In this communication the author first noticed the difficulties encountered in applying caoutchouc for insulating purposes, describing the decay of native caoutchouc, especially when exposed to air and light, arising from oxidation, and resulting in a condition of fluidity. The components of caoutchouc were stated by the author to be 84.56 carbon, and 12.33 hydrogen, agreeing almost exactly with Dr. Miller's figures in a previous analysis. In applying caoutchouc as an insulator it has been generally washed, dried, and masticated, being manufactured by the process into solid blocks, which are then cut up into sheets, which are again divided into tapes. After serving the tapes around the wires they have usually been consolidated by heat, or by the use of solvents, both of which are injurious in their tendency to favour oxidation. Wires thus insulated give good results for a short time, but their efficiency is soon destroyed. The results obtained with five specimens of india-rubber covered wire supplied for experimental purposes to the Government of India, and sent out to Kurrachee in 1863, were adduced by the author, and showed that four out of the five were defective after submersion in the Indian Ocean, one only, supplied by himself, remaining perfect. In insulation this specimen was the highest yet attained, and the perfection of the joints was fully proved. The central position of the conductor was unaltered by any elevation of temperature, and its insulation remained good up to 150 deg. Fahrenheit and even higher temperatures. The mechanical properties of the core devised by the author were also shown to surpass all other materials yet produced. The importance of the low inductive capacity of the wires insulated by the author's process was also dwelt upon. Sir Charles Bright, Mr. Latimer Clark, and Professor Thompson had made independent investigations into the capabilities of the wire thus insulated, and the results, deduced by those gentlemen were singularly in accordance with each other, the two former giving the induction of the author's wire compared with gutta serena as 100 to 136, the latter as 100 to 135. The rate of signalling being proportionate to the retardation arising from induction, the value of the process in a line of such length as the Atlantic cable would be at once apparent in a commercial as well as a scientific view.

PROFESSOR THOMSON assigns to the sun's heat, supposing it to be maintained by the apulse of masses of matter, a limit of 300,000 years; and the period of cooling of the earth from universal fusion to its actual state 98,000,000 years.

BRISTOL INDUSTRIAL EXHIBITION.—A Mr. Perry, of Yeovil, Somerset, exhibits in the Bristol Industrial Exhibition a model of a church, with a peal of bells and miniature ringers, and several small cases containing mechanical figures, railway trains, &c., the whole of which, before they can be set in motion, severally require that a halfpenny shall be dropped into the till. These working models are very attractive, and it is estimated that several pounds are dropped into the tills in the course of the day. There are 11 of these mechanical figures all belonging to the one man.

MICROSCOPY.

A GRADUATING DIAPHRAGM.—A very ingenious diaphragm (says the *Popular Science Review*) has just been devised by Mr. Collins, of Great Titchfield-street. The advantages of the new instrument can only be appreciated by those who understand the necessity which exists for regulating the amount of light which is reflected from the mirror of the microscope upon the object under investigation. In the ordinary "wheel of diaphragms" there are about half a dozen apertures of different sizes, and the observer rotates the disk until he finds an aperture which admits the proper flood of light. There are, however, two serious objections to this method:—1st, As the number of holes is limited, the microscopist, though enabled to select the best aperture of the series for his purpose, may not be supplied with such an aperture as would give the exact absolute degree of illumination. 2nd, While rotating the "wheel" to obtain the required result he loses sight of his object, and thus is unable to perceive fully the advantage he has derived from the alteration. Both these disadvantages have been overcome in Mr. Collins' diaphragm, which provides a means by which any sized aperture may be obtained without removing the object from observation. The subjoined engraving explains the apparatus. It consists of a plate, placed beneath the stage, and having below it two smaller ones, whose opposite sides are incised in a cuneate manner, and which, when separated, leave a large lozenge-shaped aperture; but, when caused to approach, gradually diminish this aperture till it is reduced to a mere point. The approximation and separation are effected by means of a screw, whose milled head is within easy reach of the observer's finger. This piece of apparatus may easily be appended to any microscope, and the manner in which it aids in the display of the striæ of enamel and muscular fibre, and the delicate markings of the diatomacea, must be seen to be fully appreciated. Obviously its greatest merit lies in the power which it gives to the observer of graduating his aperture of illumination with the greatest nicety, and of estimating the improvement in the definition of fine points of structure as he proceeds in his observation. It might appear at first that the lozenge-shaped aperture would interfere where certain varieties of illumination are required; but we think that this objection can only be urged in exceptional instances. For most of the purposes of research the new diaphragm is an immense improvement on the old one.

BOOKS ON TURNING.

The subjoined list of works on turning has been made with the intention of sketching a basis on which to found something better in the way of a *Manuel de Turning* than is yet published. Let everything old in an art be understood, and then a safe onward movement can be effected, seems to be a motto worth adopting. It is hoped that the list will be sufficiently explicit to enable any turner to select the book most suitable to his own purposes. The legion of lathes for simple screw-cutting, and those involving Blanchard's principle, are not noticed. It is hoped, soon, to supplement this with notes upon the German authorities, and the Specifications of Patents since 1855.

1. Schopper; Hartman;—"Panoplia omnium, etc" Frankfort on the Maine, 1548. Contains some illustrations of turning. Holtzapffel, page 6.

2. Besson, Jacques; of Dauphiny, France; "Theatrum instrumentorum et machinarum." Lyons, 1582. Comprises three illustrations of machines for oblique turning, oval vase, and screws upon cones and cylinders. See Plumier, *pr. face*, p. 3, and Holtz, p. 5; the latter, on p. 616, gives an illustration of his "kind of lathe, in no part ever before seen, and which is not without ingenuity; for cutting, little by little, screws on any round solid, and even on an oval one."

3. De Caus, Solomon; *les raisons des forces mouvantes*, 1624; one engraving of a lathe for ovals, no explanation.

4. Moxon; *Mechanick Exercises*, two vols. London, 1677-83. The first volume contains turning, and gives three or four illustrations, one of a lathe with roves for rose-engine work.

5. Felibien;—*Des principes de l'architecture de la sculpture*, etc.: Paris, 1690; twelve pages, describing a lathe, some oval and rose-engine work.

6. Plumier, Le pere; *Minime religieux; l'Art de tourner en perfection*. 1 vol., 4to., 60 plates, Lyons, 1701. This is the first work entirely devoted to turning. One of the silent orders of monks showered down blessings on one of their companions who introduced the turning of chalices as a recreation for leisure hours. Plumier is very complete; he has four methods of oval turning—1, by roves or rosettes; 2, by a ring adjustable at any angle upon a vibrating mandrel-frame; 3, by an eccentric in a box, "tambour"; 4, our present oval chuck, but the ring is placed vertically. The good old monk says he obtained the pattern from the Abbé Forcet of Paris. He ascribes other beautiful machines in his book, for ornamenting tool-handles to the English, but not this chuck. Abraham Sharp is said to have invented it. I believe his MSS. are still preserved; why are not the original drawings of this published? James Spackman and James Williamson patented it as theirs, in 1764. Specification No. 821. Plumier's lathes are mostly fancy ones, the swash, pump and rose work, moved both by weights

COLLINS' GRADUATING DIAPHRAGM.

and springs, are amply illustrated. His specimens of spiral and pump-work are extraordinarily fine. His fluting and handle-carving machines very interesting. He concludes his book with some stocks and dies, and screw-boxes. A rest and hook, contrived to hold the tool immovable, would be still useful where no slide-rest is obtainable.

7. Spackman and Williamson's specification of patent for lathe, for elliptical turning, quoted above. This oval chuck has two parallel slots through its back plate, one for each of the two supports to the cheeks which act upon the eccentricized ring.

8. *L'Encyclopedie Methodique*; Paris, begun in 1782, contains forty plates of turning, mainly after Plumier.

9. Gregory: *A Dictionary of Arts and Sciences*, London, 1807; contains not much that is interesting; his polishing, oval chuck, and secrets of the art, are copied verbatim from Plumier.

10. Smith, James; *The Panorama*, Liverpool, 1815; contains a good article on turning, with three admirable illustrations, badly copied into "The Turner's Companion." The oval chuck, (or elliptical, as he correctly terms it) is well drawn and explained. It contains a very primitive slide rest (anterior to Maudslay's?) and refers to one used by Earl Stanhope in his stereotyping machinery. Healy's chuck for cutting screws is also given.

11. Bergeron L. E.; *Manuel de Tourneur*: 2 vols., and Atlas, Roret, Paris, 1816. This work contains almost everything the most fastidious taste can demand. Lathes with long mandrels and screws cut on their shanks are the most common. The drawings of tools are most exact; screw cutting is fully treated of, flute making well described, and in spiral, spherical, and fancy turning, everything is given which can be desired. A fluting machine, epicycloidal chuck, eccentric do., swash mandrel, pump mandrel, rose engines (both by the tool vibrating, and the mandrel-frame), straight line chucks,

medallion engine, flying cutter, &c., furnish quite a feast to a mind mechanically inclined. Some of these apparatus have been vastly improved upon, first of all by Holtzapffel of London, and secondly, by Kennan of Dublin, but we have no descriptions of their machines in existence.

12. Perkins, Jacob; *Specification of Patent*: No. 4,400, A.D., 1819. An engine lathe for engraving surfaces, &c. This is a machine for cutting lines, generated by the action of a compound eccentric, oval, and epicycloidal action, set vibrating in a mandrel-frame, moved by an eccentric above the mandrel. There are no illustrations of the figures it would describe, but the drawing is very explicit. Plate 2 fully illustrates the former machine applied to work on the surfaces of cylinders. Four other plates have nothing to do with turning.

13. Ree's *Cyclopaedia*, London, 1819. Under turning, lathe and rose-engine are given the best description of general work. His illustrations are Maudslay's last bar lathe with its slide-rest and gearing for screw-cutting, Holtzapffel and Deyrlin's rose-engine, with a good selection of chucks, including an eccentric and oval one.

14. Rich, C. H., Southampton, 1819. Specimens of the art of ornamental turning in eccentric and concentric patterns. Six copper-plate engravings (this I have not seen).

15. Gregory's *Mechanics*, 2 vols; London, plates by Farey, London, c. 1820. A good drawing and description of Maudslay's lathe when he lived in Margaret-street, Cavendish-square. It is a bar lathe, has a dividing plate and adjustable crank-hook, as in Smith's drawing, and a vice-chuck. The slide-rest has in addition to the three usual motions another vertical one, obtained by a screw and four diagonal slots on the vertical sides of one of the foundation plates at its base. The sketch of it is most distinct, and shows the straits he was driven to in being obliged to build up his slide-rest mainly of wrought iron.

16. Whitworth's, Jos. Specifications; No. 7441, A.D. 1837. The first part and plate describe his method of driving a face-plate, by friction-rollers on its back.

17. Ibbetson, J. H. Third edition of his eccentric turning, with additions and descriptions of his compound eccentric chuck; London, 1838. This is a very prolix and peculiar description of a good double eccentric chuck, the screws of which have centre-screws acting on their extremities to keep them from end-play. The book is very dear, and its contents are to be found in Valicourt.

18. Stevens, Alex.; *Specification No. 8707*, A.D. 1840. One shape of the scroll-chuck given in this is identical with the one in Bergeron, pl. 33. The other is worked by a mechanism slightly different, both are three-jawed chucks.

19. *Supplement à tous les ouvrages sur l'art du Tourneur*. Library Roret, Paris, 1848; includes Ibbetson's work, Clement's lathe from the transactions of the Society of Arts for 1827; Whitworth's lathe; Scot and Sinclair's, and many well-written articles from French mechanical periodicals.

20. Findlay, Joseph; *Specification No. 13,030*, A.D. 1850. A lathe for turning bobbins, self-acting, and having a screw cut right hand at one end, and left-hand at the other to advance the front and back tools simultaneously.

21. *Handbook of Turning*. Saunders and Ottley, London, c. 1850. A small volume peculiarly written, much of it from No. 10. The illustrations, where they are correct copies, are indifferent, and where any variation is attempted the result is detestable, every circle, in perspective, becoming an oval with sharp angles, and some of the cylinders showing both their ends at once. The descriptions of eccentric work, gnomometer, universal cutter, and drill are tolerably good, but the illustrations are incorrect and badly executed.

22. *A Concise Treatise on Eccentric Turning*, by an amateur; published by Pelham Richardson, Cornhill, London, 1852. The most beautiful specimens of eccentric turning ably described, and well illustrated. The prefatory remarks on this and drilled or "lace" patterns, are valuable.

23. Muir, Wm.; *Specification No. 1410*, A.D. 1853. Lathe for driving a face-plate by a pinion acting on internal cogs at its back; a system of supporting

screws and yet allowing a nut to pass by; and a method of opening the nut of the leading screw and simultaneously throwing the backing mechanism into gear.

24. Journet, Pierre; Specification 1268, A.D. 1854. A nothing in the form of a jaw-chuck.

25. The Turner's Companion; published by Henry C. Baird, Philadelphia, 1856. The same book as 21, with the same naive illustrations.

26. Ash, Captain Jas.; Inventor of the elliptical cutter frame; Double-counting on the lathe. London, L. Booth, 1857. A cleverly written and well illustrated treatise on fancy turning. The designs seem far too difficult for such simple machinery as that by which they were really effected, and the consciousness of the directions affords a beautiful contrast to the wordy and egotistic writing of some of our would-be masters in turning. This gentleman's cutter is a wonderful example of making a small and easily managed tool do the work of the cumbrous epicycloidal and other chucks and ponderous apparatus of the last century.

27. Valicourt, E. de; Nouveau manuel complet du Tourneur, Paris, Librairie encyclopedique de Roret, 12, Rue Hautefeuille, 1858, 2 vols., plates, and atlas. It is an extension of M. Dessables' Manuel, including all 19, Fox's lathe, with much of the best portions of Desormeaux and Holtzapffel. Two of the lathes in it on plate 7, by M. Sevin-Talve, appear to be mistakes. Nearly all the rest of this very complete work are well described and illustrated.

28. Campin, Francis; The practice of Hand Turning; Spon, Bucklebury, London, 1861. A cursory view of the art and many of its adjuncts, inserting much that is useless, and giving no information on intricate points in turning. The portion upon change-wheels is peculiar, the rule is given on one page and the sole example thirteen pages afterwards, then it is roughly calculated, and the incorrect ratio, 178 to 73, given instead of 7 to 4. The book has many unnecessary clauses which sketch out the author's intention and the substance of which he has to repeat in the next sentence. There are also some peculiar examples of slipshod engraving, yet there are many redeeming features. A careful compilation from standard works, good engravings, and an abundance of practical hints would make a book worthy of being reckoned as the continuation of Holtzapffel's great work. H. H.

THE MANUFACTURE OF PRINTING TYPES.

Mr. J. J. C. Smith, of Philadelphia, has patented, through Mr. Newton, of 66, Chancery-lane, certain improvements in the manufacture of printing types, which we purpose this week to describe. The object of the invention is to make types from harder materials than those cast from the well-known type metal. This is effected by cutting the type with a machine adapted to the purpose from strips of metal, each having a row of type heads on one edge, which heads are made of copper by the electrolyte process, the following being the mode of proceeding:—

A complete fount of type is set up in rows, with a blank intervening between each type equal in thickness to a saw cut; between the first row of type set up in the manner described, and the next row, a ruler is placed, the top edge of which is about one-eighth of an inch below the faces of the type heads. In this manner a "forme" of sufficient size is produced, and from it moulds are taken to be used in electrotyping the heads. As soon as the electrolyte plates produced in such a mould are of the required thickness they are removed from the moulds, and the cavities on the reverse of the plates are filled with soft solder or tin. The electrolyte plate of type heads is then cut into strips, each strip forming a connected row of type heads of copper, by means of a machine, which consists of a table fitted with an adjustable guide bar, and with a circular saw that projects up through the table. To the side of the fixed guide bar a shorter guide bar is pivoted, so that its free end may be raised or lowered, as desired. Permanently secured to a projection of the pivoted bar is a plate which forms the actual guide for the plate to be sawn, as it stands in exact line with the saw, and in front of it. The saw and guide plate are each of the same thickness as that of each of the spaces between the rows of type heads in the plate to be sawn. When the sawing operation is to be performed, the pivoted bar is raised, and the plate of type heads is placed under the guide plate, which, fitting to the spaces between the rows of type heads adjusts the electrolyte

plate in exact line with the saw. The plate is fed up by hand.

The type bodies may be made in several ways, one of which consists in casting a strip of type metal on to each of the rows of type heads above described. In casting the bodies a mould may be conveniently used, consisting of two cast-iron bars, each about 15 inches long, and $2\frac{1}{2}$ inches wide, and connected by a hinge in such a manner that they may be closed on each other as the jaws of a clamp, or opened at will. A strip of brass or steel is fastened to the inner face of one bar, and in thickness equal to the desired thickness of the type bodies intended to be cast. The jaws of the mould are grooved longitudinally to receive a bar of cast-iron with a longitudinal groove on a middle line along one side thereof, the groove being about one-eighth of an inch in depth, and in width equal to the desired width of the type intended to be produced. In the groove of this bar a row of the above-described type heads is laid face downwards, and the bar is then placed in the clamp or mould, which, when closed, is filled with melted type metal, that unites with the row of type heads. These strips are afterwards cut up into single types by means of a cutting machine.

Another way of making the type bodies consists in soldering strips of rolled metal to the rows of type heads, which strips are cut up into single types by means of the cutting machine to be now described. This machine consists of a bed-plate with two V-shaped grooves, on which a sliding carriage is mounted for the purpose of bringing the strips to be cut under the action of a circular saw, and after each complete cut, withdrawing the strips from the saw before moving them up for another cut. Fitted on the carriage is a channel equal in depth to the height of the type bodies, and formed by two guide bars, divided transversely in the line of the saw. In this channel the lines of type to be cut are placed, and they are propelled forward by means of a sliding bar, which slides in a dove-tailed groove on top of one of the guide bars. This sliding bar has a hinge joint, and a small angular hook, which enters the spaces between the types, and it is connected with a lever, by which a traverse motion is given thereto. The loose end of the bar is raised by a spring when the bar is relieved from the pressure of the lever. As soon as the strips in the channel are moved so far forward as to bring the spaces between the type heads in a line with the saw, a transverse finger is pushed forward through the spaces between the type heads, so that the finger enters the cut made in the guide bars that form the channel, as before mentioned; by this means the type heads are accurately adjusted in the position necessary for them to hold while the type are being cut off. A block which moves in the box that guides the finger projects about half-an-inch beyond each end of the box, and is connected with a lever having its fulcrum on the carriage. This block acts as a grappling jaw, and serves to hold the strips, and the type being cut therefrom, firmly in their true positions while the cutting operation is going on. As soon as the person operating the machine has closed the gripping jaw he withdraws the gauge-finger and moves the carriage up to the saw, the rotation of which severs the end types from the strips. These loose types are kept in position when released from the gripping jaw by a block of metal, which fits into and is capable of being moved along the channel by the feed motion before described.

In justice to ourselves we must add that we have not seen any of the types constructed on the above method, but we do not see why some such plan should not be found of use in the larger "founts" of types in everyday use; for it is well known that, with the present types, all that fall on the floor of an office are damaged, if not totally destroyed.

FACTORIES—THE EMPLOYMENT OF YOUTH IN THEM.

The Commissioners appointed to inquire into the employment of children and young persons in trades and manufactures not regulated by law—that is, for which the provisions of the Factory Act have not yet been made operative—have just issued a fourth report, which is of a most interesting description. The trades and occupations which have been lately investigated by the Commissioners are principally connected with the metal industries of Yorkshire, London, and South Wales; but various other trades have been carefully examined into. On each of them a separate report has been made, and with it is printed the detailed testimony upon which the deductions and recommendations of the reporters are founded. These subsidiary reports are summarised

in a long general report, from which we extract some of the leading points.

The first subject treated of is the metal manufactures of the Sheffield district. This report is by Mr. J. E. White, and in it is pointed out the conditions under which the grinding trade is carried on in Sheffield. The occupation is terribly destructive of life, from the liability of the worker to inhale dust, the necessity of a constrained position while at work, and the ill-ventilated state of the workplaces, which "must be seen to be appreciated." In 1860 Dr. Greenhow found that the death rate among these men had an annual average of thirteen in the thousand, which is more than double that prevailing in rural areas. This inhalation of dust, metallic, or arising from stone, bone, ivory, and other materials, provokes pulmonary diseases. Dr. Hall also in 1857 reported of the fork-grinders, that he found them exposed to influences which had a tendency to rob them of twenty-five years of their lives, and so fill the union houses with widows and orphans. (It will be perceived here how the general public have to pay for the effect of selfishness on the part of the few employers.) And now Mr. White, in 1865, shows that the same causes of excessive disease are in operation, with the same fatal results. The average age to which the men live is 36 years, but some so long as 42. These are the horrible conditions under which the employment of children and young persons have to be considered. The children are put to the work at 10 years old, and sometimes younger—some so young as 8 or 7. Mr. White found one 6 years old, who had been working for some months with his father. The employment in which most of the young children are found is cutlery. Girls and boys begin in this at 6 and 7 years old. One was found who had begun at 5. The following terrible fact is recorded by Mr. White: "In most cases the youngest children are employed by their own parents and relations—often in consequence of the intemperate or improvident habits of their parents; and the long hours during which these children are made to work are, say the reports, 'not only cruelly, but even incredibly long.' They are worked by day and night turns; excessive overtime is thrown upon them—sometimes a quarter of a day, a half, even a whole period of twelve hours in the twenty-four. A boy nine years old, or at most ten, worked at crine-line steel-rolling three nights running as well as the days, and this under his own father. 'We should have gone so to the end of the week, only the engine broke down.' A great number of instances as hard, and nearly as hard, as this are quoted. The boys are often subjected to heavy work. 'I have seen a boy fourteen years old using a 22lb. hammer in file forging, and some who have grown completely out of form from the work.' Mr. White remarks bitterly, in reference to these cases: 'No wonder that boys sometimes fall asleep at their work, stumble, fall when the metal flooring gets 'hot and slippery,' and work is pressing, get burned or pierced with red hot iron or steel, or otherwise suffer for their supposed negligence.' The boys grow up, if they live, stunted and weakly, sometimes deformed. They are fearfully ignorant.

Here legislation most assuredly is required; and to it it will undoubtedly be shortly directed.

The report on the foundries and machine shops in Leeds and the West Riding is by Mr. F. D. Longe, and he states that the boys go to work generally at about thirteen years of age, but some between eleven and twelve. The great evil is the system of "overtime." The same was found to be the case in iron shipbuilding yards and engineers' works. In the letter-foundries of London, though the working hours are long, yet the conditions of juvenile labour are not unfavourable. The report upon the handloom carpet weavers does not require particular notice, but that upon "heald knitting" is remarkable. Few people other than those in some Lancashire villages know what "heald knitting" is. "A heald is an open knitted framework made of cotton, and fitted to looms to raise the threads of the work in the process of weaving." They are still made by hand, and in cottages children begin to aid in the work when five, six, or seven years old, and they "work fourteen hours a day as a regular thing." "I used often to go to sleep at the work"—the boy was thirteen, and had worked from six years of age fourteen hours daily—"then the knitter would hit me to wake me up." And one effect of these long hours and the nature of the work the children are put to, which is to reach over the frame as far as they can, tends to deform them. One shoulder becomes raised and the back crooked: the legs get bent. They are paid 1s. 3d. a week for this. They are deplorably ignorant. The commissioners recommend the application of legislative action in this case. An interposition of the law is recommended with

the manufacturers of umbrellas and parasol handles in the neighbourhood of Stroud; and the makers of bobbins and spindles, to which trade children are brought very young. They experience from the flying dust, with which the atmosphere of the workshop is laden, many of the evils which the Sheffield grinders suffer, and the rate of mortality is driven to a shockingly high degree. In the india-rubber manufacture the principle grievance is long hours.

The manufactures of paper and of glass are also treated on. In the first named, of the total number employed about half are females, and of these one-fourth are under eighteen years of age, while one in six is under thirteen. This will give the total number of females engaged at 500,000, about 2,000 of whom are under thirteen and 10,000 between that age and eighteen. There are about 500 boys under thirteen and 10,000 youths between thirteen and eighteen thus occupied. The report shows that it is desirable the trade should be placed under the Factory Acts' Extension Act. In respect of the glass manufacture the commissioners consider that females should not be employed in any process of manufacture in a glass house; nor boys under the age of twelve, after which age till they are eighteen the hours of work should be apportioned on a proper scale to their years. Boys and youths below the age of sixteen should be allowed a certain number of hours weekly for schooling according to the rule of the Factory Acts.

Much unfortunately, very much more, could be extracted of equally interesting matter; but our space will not permit. Enough, however, has been printed to show that the matter is one demanding legislative interference.

RANDOM NOTES.

THE quantity of hemp and other vegetable substances of the nature of undressed hemp, imported from the East Indies and the Philippines, was in 1851, 589,460 cwt., and in 1864, 2,306,752 cwt.

WAKEFIELD INDUSTRIAL EXHIBITION.—This exhibition is one of the most successful yet entered upon. Day after day flocks of eager sightseers crowd the building. It is a thoroughly well got up exhibition, and we wish it success to the end.

MR. CARBY LEV, of Philadelphia, finds that ozone checks the growth of the roots of plants. The ozone he used was generated by the action of sulphuric acid on Chameleon mineral.

A small lead shot weighing .072 gramme was found to cause 192 times its own volume of air to penetrate beneath the surface of water by being thrown into it from a height of 1½ feet at an angle of 60 deg.

MESSRS. ST. CLAIRE, DEVILLE, AND TROOST have invented a pyrometer capable of measuring a temperature reaching as high as 1530 deg. C. At this heat the inventors state copper and silver are vaporized, and feldspar perfectly fused.

PAPER pipes, 6 inches in diameter, are used in the Pewabic copper mine to convey air from one portion of the mine to the other. They are 6 inch inside diameter, are quite strong, and can be joined perfectly air-tight by a strip of canvass and a coating of tar.

ONE good Havannah cigar is found by Dr. Richardson to yield, when its smoke is condensed, a sufficient amount of poisonous matter to induce active convulsions in a rabbit, and six pipes of common shag tobacco will yield sufficient poison to destroy a rabbit in three minutes.

THE Rev. W. R. Dawes concludes that the ruddy tint of the planet Mars does not arise from any peculiarity of the colour of its atmosphere, as the redness is most apparent in the centre where the atmosphere is thinnest, and it is suggested that it arises from the colour of the soil.

A PIRX of crown or heavy flint glass, through which a discharge from a large Ruhmkorff coil is passed, undergoes a permanent molecular modification in its whole extent, losing almost entirely its rotary magnetic power, and acquiring the properties of a crystalline body, or glass suddenly cooled.

THE best coal is put on board at Newcastle for 9s. per ton; before it reaches the consumer in London it is at least doubled in price; before it reaches France it is about trebled; in the Mediterranean ports it is quadrupled; while in many remote parts of the world coal cannot be purchased for less than £3 or £3 10s. per ton.

IN consequence of official orders to that effect, all the French railways shall be compelled to adopt appliances for instantaneous communication between every part of a train at the end of the present year.

PHOSPHORESCENCE IN CONNECTION WITH STORMS AND DISEASE.

A valuable, though almost necessarily incomplete, paper on this highly interesting subject was read in Section D of the British Association Congress by Dr. Moffatt, and which provoked a long and interesting discussion. The doctor stated that the subject had been under his consideration for some time, and that his opinions had been deduced from observations extending over a period of four years. He exhibited tables to show that the atmospheric conditions under which the luminosity of phosphorus took place were those of the south or equatorial current of air, namely, a minimum of atmospheric pressure and maximum of temperature and humidity; and that those under which non-luminosity takes place are the conditions of the north or polar current, namely, maximum of pressure and minimum of temperature and humidity. The atmospheric conditions of ozone and no ozone periods were the same as those of the luminosity and non-luminosity of phosphorus. Phosphorus became luminous and ozone periods commenced on the approach of storms, and if a storm set in during a luminous or ozone period, the luminosity increased in brilliancy and the ozone in quantity. Of diseases 80 per cent. of apoplexy, epilepsy, and sudden death occurred on the days on which phosphorus became luminous. The atmospheric conditions which led to those storms, of which the telegram gave them warning, were invariably accompanied by diseases of the nervous, vascular, and muscular systems. In conclusion, Dr. Moffatt asked whether, seeing the intimate connection there was between periods of the luminosity of phosphorus and ozone periods, and of non-luminosity and non-ozone periods, and knowing that ozone is formed by the action of phosphorus on moist air, they might not reasonably look to phosphorescence for the chief source of atmospheric ozone?

THE TOY AND JEWELLERY TRADE.

IN the section devoted to economic science at the recent meeting of the British Association, Mr. Wright read a paper on jewellery and the gilt toy trade, in the course of which he traced the rise and progress of the trade in Birmingham, and remarked upon the social habits of the workmen employed in the trade as affected by their peculiar occupation. Mr. Wright stated that it was a fact, though in all probability the shopkeepers in London would not admit it, that more than one-half of the articles of jewellery in the shops between the Bank and Hyde Park in London were manufactured in Birmingham. A great improvement in the taste and skill displayed in the manufacture of jewellery had taken place within the last few years, and this was ascribed to the fact of a school of art existing in Birmingham, and an attendance at which was required by masters of their apprentices. The number of persons employed in the trade was set down at not less than 20,000. A great deal of the prosperity of Birmingham during the past few years, not alone to the jewellery trade, was ascribed to the working of the patent laws. Sir John Bowring remarked upon the question suggested by the paper—the influence of schools of art not only upon manufactures, but upon public taste—a question of great importance. He thought in this respect the public were much indebted to Birmingham, and so do we.

MR. DONALD M'KAY'S TORPEDOES.—The sailing frigate *Terpsichore*, 18, which has been selected by the Admiralty to be handed over to Mr. Donald M'Kay, of Boston, United States, to be used by him in the experiments about to be undertaken for the purpose of showing the value of torpedoes as an agency for destroying vessels of war, is now alongside the dockyard at Chatham. She has been denuded of the whole of her stores and gear, so as to leave her an empty shell, in readiness for being moored at the end of the harbour, where the trials are to take place, care being taken to place the vessel at such a spot that accidents may be avoided. To test the value of the torpedoes, 30 of them will be placed under the frigate and discharged, these consisting of six large and 24 smaller shells, which are now in course of manufacture for the purpose. The test shell will be planted in the mud, below the vessel's keel, 48 hours before exploding. Eighteen of the smaller torpedoes will be charged with 60lb. of powder, six with 75lb. each; the six large torpedoes will be charged with 460lb. weight of gunpowder, the whole being sufficient to destroy the largest iron-clad ship in the English navy. The powder for the torpedoes is the same as that in use for the ordinary rifle.

PATENT LIST.

(From the *Commissioner's of Patents' Journal*.)

LIST OF SPECIFICATIONS, &c. PUBLISHED DURING THE WEEK ENDING 23RD SEPTEMBER, 1865.

2687. Electric printing for telegraphic and other purposes, J. H. Shanks—10d.
2688. Machine for manufacturing fish-hooks, C. O. Crosby—2s.
2689. Fitting and mounting chamber utensils, B. Scale—8d.
2690. Lamps for burning magnesium, &c., J. Solomon and A. G. Grant—1s. 4d.
2691. And cooling railway carriages, G. Davis—4d.
2692. Expressing fluids, J. M. Rowan—4d.
2693. Distributing liquid manure and sowing seed, N. F. Andreason—4d.
2694. Mixing and kneading dough, &c., E. Edwards—10d.
2695. Re-burning animal charcoal, J. F. Brinjes—10d.
2696. Fire-places, F. L. Charon—4d.
2697. Stringing and tuning pianofortes, &c., W. Moody—4d.
2698. Axles, W. E. Gedge—4d.
2699. Steam engines, &c., T. Ivory—1s. 4d.
2700. Preventing the extinction of lamps, &c., P. A. Roger—8d.
2701. Applying wheels and axles, W. Rice—10d.
2702. Lighting rooms and buildings, L. Schwartz—10d.
2703. Buttons, W. Aston—8d.
2704. Tanning leather, W. Smith—10d.
2705. Clothing for horses, cattle, &c., R. Richardson—8d.
2706. Preparing writing paper, J. Forster, and H. Draper—4d.
2707. Hydraulic presses, G. Ashcroft—4d.
2708. Combining railway wheels and axles, J. Furnevall, and G. Keighley—4d.
2709. Manufacture of wadding and waterproof fabrics, E. Pilkington—10d.
2710. Signals for railway carriages, R. C. Robinson—4d.
2711. Steam or other engines, J. Drury—8d.
2712. Signalling on railway trains, F. J. Reitt—4d.
2713. Signalling in railway carriages, J. Walker—4d.
2714. Casting steel, E. L. S. Benzon—1s.
2715. Cutting or drilling metallic or other substances, C. W. Wardle, and R. McIntyre—1s. 4d.
2716. Cutting glass, &c., W. Davies, and G. Cate—10d.
2717. Photographic process, T. Fox—4d.
2718. Thrashing machines, S. Davies—4d.
2719. Brewing, &c., C. Garton and T. Hill—4d.
2720. Manufacture of hats, caps, bonnets, &c., E. T. Hughes—4d.
2721. Apparatus for checking annuities received by conductors of vehicles, W. Newbould—4d.
2722. Inkstands, E. G. Brewer—8d.
2723. Glue and size, H. W. Spencer and J. E. Bell—4d.
2724. Signalling to railway trains, J. G. Rowe—4d.
2725. Waste pipes, J. Cutler—4d.
2726. Punching, pressing, and shearing metals, W. Baylis—8d.
2727. Lighting railway carriages, &c., J. C. Brant—4d.
2728. Attaching carriage handles and door knobs to spindles, E. J. Harrison—4d.
2729. Manufacture of file blanks, J. Dodge—8d.
2730. Cigars, H. B. Harris, and J. P. Thompson—4d.
2731. Tools for screw-driving, boring, and drilling, F. S. Gilbert—10d.
2732. Cooking food, F. L. Bauwens—4d.
2733. Manufacture of steel and malleable cast-iron, F. Yates—8d.
2734. Generating combustible gases, F. Yates—10d.
2735. Centrifugal pumps, &c., H. A. Gwynne—1s. 10d.
2736. Pumping vapours and toxic-air, A. J. Fraser—4d.
2737. Spurs, R. K. Bowley, and K. T. Bowley—6d.
2738. Obtaining motive power, M. P. W. Boulton—4d.
2739. Lustring and drying fabrics, T. N. Kirkham, V. F. Ensom, and H. Brook—10d.
2740. Oil lamps, J. Sullivan—8d.

CORRECTION OF SEXTANTS.

We understand that an apparatus will shortly be added to the Kew Observatory for the important object of the ready verification of sextants; the system of distant mirrors now in use, designed by Mr. Galton and erected at his own cost, being only available in steady sunshine. The new apparatus has been designed by Mr. Thomas Cooke, the well-known optician. In principle, it consists of four collimators fixed radially, at various angles apart, round the table on which the sextant is to be laid for examination. The cross wires of the collimators in each of their combinations are to be brought successively into contact by the sextant. Then a comparison of its readings with the constant angles of construction of the apparatus determines the error of the sextant at various points of its arc. However, in practice, to avoid the cost of very large collimators, whose object-glass would suffice to include the rays proceeding both to the index and to the horizon glasses of large sextants, Mr. Cooke employs double collimators of moderate size; and he adjusts each pair to strict parallelism, by aid of a detached telescope. The coloured shades of the sextant are readily examined, by strongly illuminating the fields of two of the collimators, after contact of their cross wires has been made in the ordinary manner. On the application of Mr. Galton, backed by the recommendation of the Kew Committee, the Council of the Royal Society has allotted £80 from the Government grant, to defray the estimated cost of Mr. Cooke's apparatus, and its establishment in the Observatory at Kew. The apparatus will be erected in the basement-hall of the Observatory; and when the arrangement is complete it is hoped that the Observatory will become a place where quadrants and sextants can be verified with great facility, and where scientific travellers or officers of Her Majesty's Service may receive instruction in the use of geographical instruments.

M. R. LUTHER, the director of the observatory at Bilk, near Düsseldorf, has announced his discovery of a new minor planet, of the tenth magnitude, and the eighty-fourth of the series.

THE PORTUGUESE EXHIBITION.—The Portuguese International Exhibition was opened at Oporto on Sept. 18th with great rejoicings.

NOTES ON PHOTOGRAPHY.

COLLODIO-CHLORIDE OF SILVER.—The editor of the *American Journal of Photography* says:—"Mr. Simpson's collodio-chloride process is turning out to be a great success. We have reports from various quarters, that it has been adopted into everyday use. So far as we are informed, all those who have tried it for opalotypes find it far more simple and certain than the processes which have hitherto been used in their production. The collodio-chloride seems to us one of the most important improvements in our art which has been made for a long time."

CARBON PRINTS.—Among the photographs exhibited at the last *soiree* of the British Association in Birmingham were some carbon prints by Mr. Swan which struck us as the finest we have seen anywhere.

OBERNETTER'S ENAMEL PROCESS.—The enamels by Obernetter's process exhibited at the *soiree* in Birmingham very much resembled those by Camarsac. Mr. Dale, a member of the firm which has purchased the process, describes it briefly as follows:—"A plate of glass is coated with a mixture of gelatine, glycerine, grape sugar, and bichromate of ammonia, and then exposed under a transparent positive. The light hardens the portions upon which it acts, and leaves the rest tacky. The colour, consisting of a vitreous powder mixed with soap-powder, is then applied to the surface, to which it adheres in due gradation. So far the process does not appear to differ materially from that of M. Joubert. Instead, however, of being burnt in at once, the print is now transferred to a convex enamel plate. To effect this the picture is coated with collodion: the film of collodion being lifted up brings with it the picture, which is then placed on the enamel plate. The collodion is next removed by dissolving with ether, as it would interfere with the process of burning. The picture is then placed in the muffle and burnt in the usual manner."

FOR SALE. A Self-acting, Turning, and Screw-cutting Lathe, 64 inch centre, with bed 6 feet long; also a second-hand planing machine, to plane 4 feet by 2 feet. Apply to W. Blackett, Hope Iron Works, 106, Southwark-bridge-road, London.

JOHN SHEPPARD, of 10, Marsden-square, Manchester, has specially adapted himself for the supply of **ENGINE-CLEANING WASTE**, at the following prices: White at £25 per ton; grey, £25 per ton; coloured, £21 per ton. Wadding Material for wadding manufacturers, at equally low prices, in bleached, crimson, grey, and black. Liberal terms to shippers.

INVENTORS ASSISTED

IN Securing, Carrying out, and Disposing of their Inventions.—Apply to Messrs. B. BROWNE and CO., British and Foreign Patent Office, 49, King William-street, London-bridge.

A Pamphlet gratis, on Cost of Patents, may be had on application

THE LONDON DRAWING ASSOCIATION for supplying Engineering, Mechanical, Architectural, and General Drawing, Designs, Maps, Plans, Tracings, Wood Engraving, Electrotyping, 7, Duke-street, Adelphi, London. Enclose stamp for prospectus.

T. E. TAYLOR.
MODELLER OF NEW INVENTIONS,
LATHE, TOOL MAKER,
AND GENERAL MACHINIST,
110, FETTER-LANE, FLEET-STREET, LONDON, E.C.
Patterns made to drawing.

W. SPEECHLEY,
ENGINEER, MACHINIST,
AND LATHE MAKER,
No. 118, RAILWAY ARCH, VAUXHALL-WALK, S.

JAMES LEWIS,
(Late Lewis & Son),
ENGINEER, MACHINIST, LATHE & TOOL
MAKER, and Modeller of New Inventions,
41, GREAT QUEEN-STREET, LINCOLN'S INN-FIELDS.
(Late of 5, Wynd-street, Strand.)
Machinery made to Drawings or Patterns, and Worked
out to Scale.

**ENGINEERS, MACHINISTS, AND TOOL
MAKERS.**
PATTERNS MADE TO DRAWING BY
C. POLLARD,
No. 3, ALGERIA STREET, BESTON HILL,
LEEDS.

W. & A. GLOVER,
ENGINEERS, MACHINISTS,
LATHE, AND TOOL MAKERS,
191, OLD KENT ROAD.
SCREW CUTTING, TURNING, AND PLANING.

CIRCULAR SAW BENCHES
FOR FOOT OR STEAM POWER.

Suitable for Cutting
Brass, Ivory, Hard-woods, Picture-frame Work, &c
All kinds of Machinery made to order.
HUMPHREY AND HASLER, 69, Old-street, St. Luke's,
London, E.C.

WHEEL, RACK, AND SCREW CUTTING.
SPUR, BEVEL, RATCHET, WORM AND INTERNAL
WHEELS cut to any size or number of teeth; also racks of any
length or pitch. Dividing plates drilled or lined. Screws cut to any
size or pitch. J. Wilkinson, Engineer, St. George's Works, 83, St.
George's-road, S. London.

TUCK'S PATENT STEAM
PACKING.

TUCK'S PATENT ELASTIC
PACKING AND METALLIC
LININGS FOR STEAM-EN-
GINES, PUMPS, &c.

ADVANTAGES.—A more perfect
vacuum is obtained. Friction
reduced, great saving in oil and
tallow, and the Packing is gradu-
ally and completely worn
away without becoming hard.

THUS OBVIATING THE NECESSITY OF DRAWING THE OLD
PACKING.

J. H. TUCK & CO., 85, CANNON STREET, E.C.

VULCANISED INDIA RUBBER GOODS.
VALVES, WASHERS, HOSE, MILL BANDS, &c
J. H. TUCK and CO., 85, CANNON STREET, E.C.

MODELS AND PATTERNS

for
**INVENTORS, MACHINISTS AND
ENGINEERS.**

Made in all their branches by
G. TAYLOR,
140, St. John-street, West Smithfield.

NATIONAL BOILER INSURANCE
COMPANY (LIMITED).

27, LEADENHALL-STREET, LONDON.

JOHN SMITH & Co.,
ENGINEERS AND BOILER MAKERS,

Sole London Agents.
All Boilers supplied by this firm insured the First
Twelve Months Free of Charge.

TO SECURE INVENTIONS by Patent
right at home and abroad, consult Messrs. TONGUE
and BIRKBECK (gratis) 84, Southampton-buildings, Chan-
cery-lane, W.C.

To Electricians.
GAS CARBON (not compressed) Cut in Plates
or Blocks for Batteries
Price Lists, on application with stamped envelope.
P. HENDERSON, 3, Park-hill, Clapham, Surrey.

NOTICE.—Removing to No. 122, from 132, LONG
ACRE, LONDON, W.C.—C. RUFFELL, Manufacturer of Im-
proved Engineering, Surveying, and Drawing Instruments for Home
or Foreign service. Every instrument of the finest quality at very
reduced prices. Standard Measures of all Nations. Post-free Cata-
logues. Forwarded to all parts on remittance or London reference.

COPY YOUR LETTERS.—HENDRY'S
GUINEA COPYING PRESS, with Screw, the cheapest and
best ever offered, to be had from W. T. HENDRY and Co., Engi-
neers 75, Queen-street, Chesham.

In case, folded for the pocket, or on roller, price 5s.
DR. REKHORST'S ENGINEER'S Manu-
facturer's, and Miner's VADE-MECUM, giving in five languages,
300 technical terms in common use among Engineers, Manu-
facturers, Miners, &c. London: F. Pittman, 20, Paternoster-row, E.C.

SCREW CUTTER'S GUIDE,

Price 1s. 6d., or stamps.
Containing 115 Pages and nearly 2,000 Trains of Wheels, all different
threads and pitches.
Tables for Tap making for Engineers, 1 to 6 inches, Gas Taps 1/2 in. to
1 inches, Mr. Whitworth's thread and many others.
A Lithograph showing a new radius gear invented by the author
of this work.
May be had at James Martin, 19, Wilson-street, New Cross-road,
Deptford, Kent.

W. LANGTON'S
PATENT
SELF GENERATING
GAS STOVE

BOILS or Frys by Methy-
lated Spirits generated
into Gas, free from smoke
or smell, and is the most
useful and economical in-
vention for the purpose
ever offered to the public.

Sold by all Ironmongers,
and at the Manufactory,
36, CHARLES-STREET,
HATTON GARDEN.

NEW WORKS PUBLISHED

BY

E. & F. N. SPON,
16, BUCKLERSBURY.

Just published, 8vo. cloth, price 18s.

PRACTICAL SPECIFICATIONS OF WORKS
executed in ARCHITECTURE, CIVIL and MECHANICAL
ENGINEERING, and in ROAD-MAKING and SEWERING: to which
are added a Series of practically useful Agreements and Reports.
By JOHN ELENKARY, Civil Engineer and Architect.

London: E. and F. N. Spon, 16, Bucklersbury.

Royal 82mo. roan, price 5s.

**A HANDBOOK FOR ARCHITECTURAL
SURVEYORS**, and Others Engaged in Building.
By JOHN THOMAS HURST, C.E.

Contains.

Formula useful in Designing Builders' Work.
Tables of the Weights of Materials used in Building.
Memoranda connected with Builders' Work.
Architectural Measurement.
Constants of Labour.
Valuation of Property.
Summary of the Practice in Dilapidations.
Scale of Professional Charges for Architects and Surveyors, with
various useful Tables and Memoranda.

London: E. and F. N. Spon, 16, Bucklersbury.

Just published, elephant folio, cloth, price £2 5s.
Kept also in Lamp Binding at the same price (can be rolled up in a
small compass without injury to the plates).

**PRACTICAL ILLUSTRATIONS of LAND
and MARINE ENGINES** showing in Detail the Modern
Improvements of High and Low Pressure Surface Condensation,
Superheating, together with Land and Marine Boilers.
By N. P. BURGESS, Engineer.

London: E. and F. N. Spon, 16, Bucklersbury.

Royal 82mo. roan, 4s. 6d., post free.

**RULES for DESIGNING, CONSTRUCTING,
AND ERECTING LAND and MARINE ENGINES and
BOILERS.**

By N. P. BURGESS, Engineer.

London: E. and F. N. Spon, 16, Bucklersbury.

Eighth Edition, in royal 82mo. roan, price 4s. 6d. post free.

**A POCKET BOOK of USEFUL FORMULÆ
AND MEMORANDA**, for Civil and Mechanical Engineers. By
GUILDFORD L. MOLESWORTH, Memb. Inst. C.E.

London: E. and F. N. Spon, 16, Bucklersbury.

Just published, on a Sheet, price 1s.

DELANEY AND OKE'S WAGE TABLES for
ENGINEERS, SHIP-BUILDERS, CONTRACTORS, BUILDERS,
&c., from a quarter of an hour, in regular progression, to nine hours
and three-quarters, and from one day to ten days, at 1s. to 8s. per
day.

London: E. and F. N. Spon, 16, Bucklersbury.

Just published, royal 8vo., price 7s. 6d.

THE SEWING MACHINE: Its History,
Construction, and Application. Translated from the German
of Dr. HERZBERG, by UFFIELD GREEN. Illustrated by Seven
large folding Plates.

London: E. and F. N. Spon, 16, Bucklersbury.

600 pages, crown vo., price 10s. 6d.

PERPETUAL MOTION. Its History during
Three Centuries; with ample Descriptions and Illustrations.
By HENRY DICKES, Civil Engineer.

London: E. and F. N. Spon, 16, Bucklersbury.

Royal 8vo. cloth, Illustrated with 41 Plates, price 16s.

**A PRACTICAL TREATISE on the SCIENCE
of LAND and ENGINEERING SURVEYING, LEVELLING,
ESTIMATING QUANTITIES, &c.**, with a General Description of the
several Instruments required for Surveying, Levelling, Plotting, &c.
By H. S. MERRITT.

London: E. and F. N. Spon, 16, Bucklersbury.

Just Published, royal 4to., half-bound, Illustrated by 84 Plates of
Furnaces and Machinery, price £3 2s.

**THE IRON MANUFACTURE of GREAT
BRITAIN**, Theoretically and Practically Considered; including
Descriptive Details of the Ores, Fuels, and Fluxes employed; the
Preliminary Operation of Calcination; the Blast, Refining, and
Puddling Furnaces, Engines and Machinery, and the various Pro-
cesses in Union, &c. By WILLIAM TRURAN, C.E. formerly En-
gineer at the Dowlais Iron Works, under the late Sir John Guest,
Bart., subsequently at the Herwall and Forests Works, under Mr.
Crawshaw. Third Edition revised from the Manuscript of the late Mr.
Truran. By J. Arthur Phillips, Author of "A Manual of Metallurgy,"
"Records of Mining," &c., and W. H. Dorman, C.E.

London: E. and F. N. Spon, 16, Bucklersbury.

Just Published, post 8vo. cloth, 3s. 6d.

**MEMOIRS of the DISTINGUISHED MEN OF
SCIENCE of GREAT BRITAIN, LIVING A.D. 1807-8.** By W.
WALKER, Jun., with an Introduction by Robert Hunt, F.R.S.
Second Edition, revised and enlarged.

Containing the lives of Watt, Bessie, Telford, Mylne, Jessop,
Chapman, Murdoch, the first to introduce gas into practical use;
Bamford, Huddart, Boulton, Brunel, Watson, Bentham, Maudslay,
Dalton, Cavendish, Sir Humphry Davy, Wollaston, Hatchett, Henry,
Allen, Howard, Smith, the father of English geology, Croxallton,
inventor of the Spinning Mule; Cartwright, Tensent, Ronalds, the
first to successfully pass an electric telegraph message through a long
distance; Charles Earl Stanhope, Trevithick, Nasmyth, Miller, of
Dalewinton, and Symington, the inventors and constructors of the
first practical Steamboat; Professor Thomson, of Glasgow; Troughton,
Donkin, Conner, Herschel, Meeley, Raily, Frodsham,
Lennie, Playfair, Rutherford, Dollond, Brown, the Botanist; Gilbert
and Banks, the Presidents of the Royal Society at that epoch of
time; Capt. Kater, celebrated for his pendulum experiments; Dr.
Thomas Young, and Jenner, the benefactor of mankind; Jas. Ivory,
Dr. Priestley and Cort, the father of the Iron trade.

London: E. and F. N. Spon, 16, Bucklersbury.

UPFIELD GREEN,
JOINERS' HALL BUILDINGS, 79, UPPER THAMES STREET, E.C.,
LITHOGRAPHER, PRINTER, ARTIST, AND DESIGNER,
 PLANS, DESIGNS, SPECIFICATIONS, AND EVERY DESCRIPTION OF ENGINEERING DRAWINGS EXECUTED WITH
 RAPIDITY AND ECONOMY.

NOW PUBLISHING, PART IV., VOL. I., OF
THE ILLUSTRATED
BUILDERS' JOURNAL,
 A Paper devoted to the Interests of all connected
 with the
ENGINEERING AND BUILDING TRADES.
 CONTAINING 80 HANDSOME 4TO. PAGES, ENRICHED BY
 NUMEROUS PRACTICAL ENGRAVINGS, PRICE 11D.

THE ILLUSTRATED BUILDERS' JOURNAL
 is the cheapest and most practical work on Architecture published in England. Among the Contents of Part IV., Now Ready, will be found:—Muir's Improvements in Public-houses and Taverns, with elevation and plans—Where Artists Come From—District Surveyors and their Fees—The Cisterns of Venice—Roofing Plates—Workingmen's Exhibitions—Notes on the Emery Trade—The Artisan and his Friends—Boham Church, near Chichester—New Church at Brussels—Stoneware—Tool Borrowers—Altar Hangings—Barr's Machinery for Moulding Pipes—Rhevyd Slate Quarry Company—Experiments in Ventilation—The New Law Courts—Opening of New Blast Furnaces—Law Notes—The Building Trades—Leaving Work Without Notice—The Labourers' Strike at Culbitt's—Acoustic Properties in Rooms—Preservation of Timber—Stained Glass—Oriel Window at Sheppabury, with engraving of elevation and details—The Desired Dictionary—Mr. Lazard on Working Men's Clubs—Parade Pictures—Gas and Water Pipes—Brick Cottages—The Architectural Museum—London Improvements and London Poor—Beneath the Foundations—House Building Companies—The New Proposed Exchange for Manchester—Mr. Potter and the Trades' Unions—Clifford's Suspension Bridge—Trade Disputes—Accidents to Operatives and Others—Notes on Churches and Chapels—News from Scotland—Progress in the Provinces—General Notes—American Boring and Morsing Machine, with engravings—Stoneware, with illustrations—London Bridge—The National Provincial Bank of England—A New Northern Watering Place—Examples of Brick Window Heads, with five engravings—The Virtue of Application—An Apology for Harley Street and its Likes—A Town without Water—The British Association—Society of Wood Carvers—The Ruins of Bury Castle Discovered—The Royal Insurance Buildings—City of Milan Improvements Company—London Bridges—Movements in the Trade—The Sanitary Condition of the City of Dublin—Nicola Pissano's Pulpit—Castle Pierrefonds—Willenhall and its Locksmiths—Accidents to Operatives and Others—Battersea Park—The Position of the Worker—Clark's Window Sash Lock, with illustration—The Clays of Cornwall and Devonshire—The Nail Makers of Dudley—On Bonding, with illustrations—Examples of Cast and Wrought Iron Work, with illustrations—Sir Joseph Paxton and Sir Christopher Wren—Smithfield Improvements—Stone Breaking and Cutting—Architecture and Building at the British Association—Toll Bridges over the Thames—The Cannon-street Railway Bridge and Station—Union Bank of London, the Temple Bar Branch—The Works of the Thames Embankment—Improvements in Windsor Castle—Water Supply in London—Building News from the Provinces—Improved Dwelling Houses—Supply of Water to Towns, with large engraving—Wood Working Machinery for New Zealand—Railway Smoke—Underground Foundations—More Houses for the Working Classes—Examples of Brick Chimney Caps, with numerous illustrations—Street Cleaners—Birmingham Town Hall—Building Woods—Public Works in France—Limes, Cements, Mortars, and Concretes—Wolverhampton and its Artisans—The Cannon-street Extension of the South-Eastern—Ventilation—Slagg's Self-Closing Door, with illustration—Rapid Sawing—Letters to the Editor—Compensation Cases—Property Record—Tenders Sent In—Contracts Open—Competitions Open—Proposed Building and Engineering Works Open for Tender—Prices of Materials—Bankrupts in the Building Trades, &c., &c.

PRICE ELEVENPENCE.

"EXCELSIOR," "EXCELSIOR"
Family Sewing & Embroidering Machine
 WITH ALL THE LATEST IMPROVEMENTS.

IS easy to operate, simple to learn, quiet in action, and not liable to derangement. It will TUCK, HEM, FELL, GATHER, CORD, QUILT, BRAID, and sews from two ordinary reels, requires no re-winding, and the seam, if cut at every inch, will not rip. Price from £6 6s.

WHIGHT AND MANN, 143, HOLBORN BARS, LONDON.
 MANUFACTORY—GIPPING WORKS, IPSWICH.
 PRICE LISTS FREE.

GEORGE CUTLER, Junr., MANUFACTURING ENGINEER, LONDON GAS-HOLDER AND BOILER WORKS, 8, WHARF, WENLOCK ROAD, CITY ROAD, N., LONDON.
 Contractor for Tanks, Gas-holders, Roofs, Purifiers, and all descriptions of Gas Apparatus executed on the most reasonable terms. Steam and Range Boilers of the best material and workmanship on the shortest notice.
MAKER AND PATENTEE OF THE GAS HEATED STEAM BOILER.
 Slide and Bypass Valves for Gas or Water Works, Bolts, Rivets, Retort Screws and Doors kept in Stock. Gas Works supplied and erected complete with main and service laying.

RAMSBOTTOM'S
PATENT DISPLACEMENT LUBRICATOR
 FOR LUBRICATING THE PISTONS, CYLINDERS,
 AND VALVE FACES OF STEAM ENGINES.

THIS Lubricator is very simple, efficacious, requires little attention, has no mechanism to be deranged, effects a great saving of the Lubricant, and a reduction of friction, and consequently of the working faces exposed to the steam. It is applicable to every form of Steam Engines, Marine, Stationary, Locomotive, and Agricultural, Steam Hammers, and other Machines actuated directly by Steam. Prices, 26s. 6d., 35s. 6d., 45s. 6d. Particulars to be had of the Manufacturer,
 J. CASARELLI, 43, Market-street, Manchester.

No Fitter or Turner should be without a Straight-edge.

The most reliable tool of this kind, graduated to the Standard Measure of the Realm, and manufactured with MARVELLOUS ACCURACY, may be obtained of

RICHARD LLOYD,
MILL AND MACHINE IRONMONGER
 135, STEELHOUSE LANE, BIRMINGHAM.

Clubs of Workmen supplied at reduced prices. No equal tool is sold under FOUR TIMES THE PRICE

CHANGE WHEELS FOR SCREW-CUTTING LATHES.

NOTICE TO INVENTORS.—Office for Patents, 4, Trafalgar-square, Charing-cross. Printed instructions (gratis) as to the Cost of PATENTS, for Great Britain or foreign countries. Advice and assistance in disposing of or working inventions. Branch offices and agencies in every Continental State and in America. Established 80 years. Full information as to expired or existing Patents at home or abroad. Apply personally or by letter to Messrs. PRINCE and Co., Patent Office, 4, TRAFALGAR-SQUARE, CHARING-CROSS, W.C.

TO INVENTORS.—GENERAL
PATENT OFFICES.—L. de FONTAINEMOREAU, 4, South-street, Finsbury, London; 16, Rue de la Fidélité, Paris; 32, Rue des Minimes, Brussels. Provisional protection, £7; to complete patent, £30; French patent, £6 10s.; Belgium, £2 10s. Circular gratis on application.

INVENTIONS PROTECTED BY
PATENT OR REGISTRATION, at fixed and most moderate charges. The Inventors' Manual free by post, or gratis on application.—Apply to Mr. BREWER (late Barlow and Co.), 89, Chancery-lane, London, W.C. Established 21 years.

W. JONES
DIE SINKER,
EMBOSSER AND ENVELOPE MAKER,
MACHINIST,
 PRESS AND BRASS LABEL MANUFACTURER,
 246, HIGH HOLBORN.

HOLLOWAY'S OINTMENT AND PILLS.—All persons afflicted with Bad Legs, Sores, Ulcers, and Skin Diseases, who from want of means or other reasons cannot avail themselves of surgical treatment, may release themselves of their complaints by using Holloway's purifying, soothing, and healing remedies. In outward ailments this wonderful Ointment brings about the most beneficial results, by checking inflammation, cleansing ulcerations, and restoring soundness. Internal pains, rheumatic and gouty tortures, enlarged joints, scrofulous swellings, and contracted sinews, may be overcome by diligently rubbing this cooling unguent into the skin. In all maladies of unusual severity or excessive duration, the Pills should be taken internally to root out the last seeds of the disorder, and to haste the desired cure.

PATENT HOLLOW STEAM PACKING.

THE great and peculiar advantages of this packing consist in its remaining perfectly elastic, and is so constructed and applied that the pressure of the steam itself makes the joint by entering the packing from the cylinder; thus the many objections to packing previously existing are effectually removed. Vulcanised India-rubber Sheet Washers, Valves, Springs, Hose, Glazed and Solid Tubing for Gas, Speaking Tubes, Diving Dresses, Gas Bags, Air-proof Goods, or any description of India-rubber articles made to order.

Price list or circular, with full description of packing, to be had of the only Manufacturers and Patentees of Hollow Steam Packing.

FOSTER and WILLIAMS, India-rubber Works, Cowper-street, City-road.

LUBRICATING OILS.—By a newly discovered process (without acids) all gummy and sticky matter is perfectly removed. This oil, being a pure fatty substance, with a dense consistency, accelerates the motion of machinery, is more durable and economical than any in use. Cash prices—spirit and sewing machine oil from 4s. 9d. to 5s. 3d.; dense oil for heavy machinery, from 5s. to 5s. 9d.—Oil Wharf, Stainsby-road, Limehouse, London, E.

TO ENGINEERS (Civil and Mechanical), Patent Agents, Inventors, Architects, Builders, Iron Founders, &c.

Patterns for Castings, Models for Locomotive and other Engines, Ships, Carriages, Bridges, Permanent Way, and every description of Machinery made to order, Templates, Working and Finished Drawings, Tracings, &c., Models, and Plans for Trials.—New Inventions practically carried out full size or to any scale. Iron, Brass, and Malleable Iron Castings supplied, by **MACMORRAN & Co., Ltd., Salisbury Court, Fleet-street, E.C.** Agents for Lupton's Patent Gas Engines.

N.B. Prospectuses and space papers for the City of London Working Classes Exhibition, and all information given.

W. R. GIBSON,
DRAUGHTSMAN AND ENGRAVER ON
WOOD, LITHOGRAPHER, &c.
EAST TEMPLE CHAMBERS, WHITE-
FRIARS STREET, LONDON, E.C.

THE EVAPORATER SURFACE CONDENSER (PERKINS'S PATENT).—This simple apparatus, having now been in use for some years, can be strongly recommended as very effective and economical.

A vacuum of 28 in. can be readily obtained by evaporation alone, and all the water now required for the ordinary condenser is dispensed with entirely, and pure water is returned to the boiler, thus avoiding all sediment, &c. In non-condensing engines the water is returned to the boilers at a temperature of 212 deg.; and, by the addition of a donkey air-pump, all the advantages of a condensing engine is obtained.

References and estimates given on application to the Manufacturer and Patentee, **A. M. PERKINS, 6, Seaford-street, Regent's-square, London, W.C.**

W. H. PEARCE,
LATHE AND TOOL MAKER,

PRIZE MEDALS.
INTERNATIONAL EXHIBITION, CLASS I. AND II.

PATENT PLUMBAGO CRUCIBLES.—The Crucibles manufactured by the **PATENT PLUMBAGO CRUCIBLE COMPANY** are the ONLY kind for which a MEDAL has been AWARDED, and are now used exclusively by the English, Australian, and Indian Mints; the French, Russian, and other Continental Mints; the Royal Arsenal of Woolwich, Brest, and Toulon, &c., &c.; and have been adopted by most of the large Engineers, Brass Founders, and Refiners in this country and abroad. The great superiority of these Melting Pots consists in their capability of melting on an average Forty Pourings of the most difficult metal, and a still greater number of those of an ordinary character, some of them having actually reached the extraordinary number of 96 meltings.

They are unaffected by orange temperature, never crack, and become heated much more rapidly than any other crucibles. In consequence of their great durability the saving of waste is also very considerable.

The Company have recently introduced Crucibles especially adapted for the following purposes, viz.:—**MALLEABLE IRON MELTING**, the average working of which has proved to be about SEVEN DAYS; **STEEL MELTING**, which are found to SAVE NEARLY A TON AND A HALF OF FUEL TO EVERY TON OF STEEL FUSED; and for **ZINC MELTING**, lasting much longer than the ordinary Iron pots, and saving the great loss which arises from mixture with iron.

The Patent Plumbago Crucible Company likewise manufacture and import Clay Crucibles, Muffles, Portable Furnaces, &c., Stove Backs, all descriptions of Fire Standing goods, and every requisite for the Assayer and Dentist. For Lists, Testimonials, &c., apply to **THE PATENT PLUMBAGO CRUCIBLE COMPANY, BATTERSEA WORKS, LONDON S.W.**

COPPERSMITHS, AND ENGINEERS,
BRISTOL
Sole Makers of Clements'

ECONOMIC LUBRICATOR,
FOR MARINE, LOCO, AND FIXED STEAM-ENGINES.

(As supplied to the Admiralty, and many Engineering and Steamship Companies.)

This Lubricator offers a perfect method of lubricating all the internal parts of the steam-engine, by the vaporisation of the lubricant, saving, at least, half of the oil or tallow generally used, and lessening the "wear and tear" consequent upon imperfect lubrication.

PRICES, COMPLETE, WITH GUN-METAL FITTINGS:—

2 Pints, 62s. 6d.; 3 Pints, 67s. 6d.; 4 Pints, 75s.

BRIGHT GUN-METAL BODIES, EXTRA.

As they are fixed on the steam-pipe, the diameter of this should be given; and it should also be stated whether horizontal or vertical.

BRITISH AND FOREIGN PATENTS AND THE REGISTRATION OF DESIGNS.

MR. H. H. MURDOCH having succeeded to the business of his late Father, which has been established nearly Thirty Years, offers his professional services to Inventors. A circular, containing full information respecting the various modes of securing protection for inventions at home and abroad, may be had, Gratis, by applying (personally or by letter), at his OFFICE FOR PATENTS, 7, STAPLE INN, LONDON.

PATENTS.

MR. VAUGHAN, Member of the Society of Arts, British, Foreign, and Colonial Patent Agent, 64, Chancery-lane, W.C. Transacts every description of business connected with Letters Patent for Inventions, Provisional protection, &c to 8 guineas. A "Guide to Inventors" free by post.

ENGLISH MECHANIC:

A Record of Mechanical Invention, Scientific and Industrial Progress,
Building, Engineering, Manufactures, Arts, &c.

VOL. II.—No. 29]

FRIDAY, OCTOBER 13, 1865.

[PRICE ONE PENNY.]

SADLER'S GAS HEATED STEAM BOILER.

We this week make room for a little gas-heated boiler, the invention of Mr. P. H. Sadler, draughtsman, of 4, Richmond-place, Richmond-road, Dalston. It is one of a numerous variety, but has some points which will recommend it to those using model-sized engines, and for amateur experiments. It will be observed that there is attached a simple apparatus for preventing steam rising above a certain point, thereby effecting a saving in the gas. This consists of a small cylinder fitted with a piston and a rod communicating with the gas supply, the piston being kept in its place by a spiral spring, the power of which is regulated according to the desired pressure.

This form of boiler is the strongest, being a perfect sphere in two halves, and having an outer covering forming a chamber for the heated air passing from the under portion of the boiler. This is effected by having holes made in the two middle flanges.

Fig 1 is a section of the boiler; b is the gas supply; c, the feed pipe, which being at the bottom of the boiler serves as the blow-off pipe also; e, is the cylinder for regulating the pressure; d, is the tank; f, f, are brackets for supporting the gaspipes; g, is a screwed joint to enable the boiler to be cleansed; a, a, chamber for hot air. Fig 2 is an elevation of the boiler, showing its real appearance, which when this is studied the boiler can be turned

in the lathe after being properly worked on the anvil. This is impossible where plates and rivets are used.

Mr. Sadler in his communication expresses the hope that his "modification" will be acceptable to our readers.

THE value of water-tight compartments in steamers was well illustrated in the case of a collision on Lake Huron, one of the unfortunate vessels having been taken into port sixty miles or more from the scene of the accident, an unsightly wreck forward, great plates of iron hanging by shreds, bent, twisted, and torn, but the joints of her first partition tight as a steam boiler.

ANSWERS TO CORRESPONDENTS.

ELECTRICITY.

TO OUR READERS.—In answer to J. H. S., "Walter Harrington," and others, it is not our wish to stop "all correspondence on electricity." It is our intention to give a fair space to letters and articles from the pens of telegraphists and electricians, but for the sake of such of our readers whose pursuits are purely engineering and mechanical, we feel bound to avoid filling the columns of THE ENGLISH MECHANIC weekly with mere repetitions of questions and answers. We shall, next week, give a full description of Winter's electrical machine, accompanied by engravings.

ELM CHURCHMAN.—Griffiths, Clerkenwell-green. Other chemists may keep it on sale.

SEVERAL MECHANICS.—Let one of you go to the office of the examiner, London-bridge (the local Marine Office), and everything may be learnt there; or a letter to the secretary, Marine Department, Board of Trade, Whitehall, will do. Spou publishes a "Guide" at 3s.

SAM. GOODWIN.—Try point heating to cherry red, and plunging in oil.

A. B. Z.—It no longer exists. You will readily find the other by overhauling your back numbers.

ISOMETRIC.—In preparation, and will shortly be noticed.

J. C. (Paisley).—Accept our thanks: you will perceive your kind answer has been anticipated.

YOUNG MECHANIC.—See answer by "John Swift."

WM. SLATER.—The matter is closed.

—See answer to "Isometric."

J. BROWN (Reading).—Bennet's book (238 Spou's catalogue), 3s. 6d., might suit you; Boyer's book, 1s. 6d., No. 249, same catalogue; Brown's, 25s. 1s. 6d. An advanced work is that by T. L. Donaldson, 2s. 2d. Get Spou's catalogue, and there select.

INGHO.—We think your query has been answered two or three times already.

ALPHA.—Both of your queries you will often find answered in the advertising columns of the daily press.

AARON LLOYD.—See "Notes and Queries." No necessity for apology. The books recommended are generally asked for.

THOMAS GRAY.—We are sorry to say that under the present law the patent has lapsed. There can be no harm in your going up to the office, and questioning one of the obliging men there on the matter; they may show you a hole to creep in by.

J. H. M. (Manchester).—We are sorry, but that correspondence is closed. We did not receive the other. Send it on again—as brief as possible—and in it will go. Thanks for all this remainder, which see.

J. WAKFIELD.—Thanks for your letter.

JOCK.—You have been answered in this column, at some length. Why call your intelligent class "scurvy and greasy"? We have never found it so, rather "other" from "Canonsville to Piesance," and from "Holyrood to Rest-and-be-thank't." So, Jock Forbes, if you can get your hours shortened, without doing anyone injury, do so; with our best wishes. We may just add that we have yet to make the acquaintance of "the combination" of which we are afraid.

G. C. GOODE.—Register it, yourself, at the Patent Office.

. We have to ask our correspondents to sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them by the thousand; the same with "Well-Wisher," &c. If they don't like to see their own names paraded, use those of an ancient or any other man.

Several letters remain over till next week tomorrow.

Letters applying for information to be furnished by post cannot be attended to.

Correspondents are requested to keep copies of their drawings and manuscripts, as the Editor cannot undertake to return such as may be rejected.

AN AERONAUTIC SOCIETY.—So much interest has of late attached to the subject of aerostation—partly attributable to the publication of Mr. Hutton Turner's "Astro Casto"—that it is in contemplation to establish an Aeronautic Society. Mr. Glaisher, F.R.S., Dr. Lee, and other learned men have signified their intention of being members of the council; and it is understood that, as practical matters are always foremost in the minds of Englishmen, the society will make it their first object to facilitate both ascension and descension without waste either of gas or of ballast. They hope afterwards to apply aerostation for the purpose of foreign exploration and military observation.

THE FRICTION BREAK.—Mr. Charles T. Porter has made some careful experiments, in which the power of a steam-engine was simultaneously measured by the friction break and the indicator. They show so singular a discrepancy, that he has concluded the friction-break to be a fallacious test of engine-power. No satisfactory explanation of the difference has yet been suggested. The power calculated from the weight on the break is greater than that shown by the indicator.

THE BERNETT PATENT FILE COMPANY are now, after surmounting many difficulties, manufacturing files by their new automatic machinery. The apparatus for rolling the most difficult forms of taper files has been perfected. It is now in course of erection at the works at Smethwick, and will shortly be in operation.

BARON SWEDENBORG.

The mention of this philosopher's name, casually, a week or two since, in a short article, appearing in our columns, having evoked sundry inquiries from correspondents evincing a desire to know more of this great man, we have made arrangements with a gentleman to supply us with a BIOGRAPHICAL REVIEW, and PORTRAIT; the first section of which will appear, if possible, in our next.

THE ENGLISH MECHANIC!

Just Ready, and now Publishing, the

FIRST VOLUME

of

THE ENGLISH MECHANIC.

A Record of Mechanical Invention, Scientific, and Industrial Progress.

UPWARDS OF ONE HUNDRED ILLUSTRATIONS.

Handsomely bound, gilt edges, 4s. 6d.; post free, 5s. GEORGE MADDICK, 162, FLEET-STREET, LONDON, and all Booksellers.

THE ENGLISH MECHANIC.

Every Tuesday, One Penny. Monthly Parts, 5d. Now Publishing, complete, the First Volume.

. Title Page and Index, One Penny. Cases for binding, One Shilling and Sixpence.

It is solicited that all back Numbers be ordered at once.

All the early Numbers have been reprinted. It is therefore necessary that sets be made up at once, as there will be no further reprints owing to the great expense they entail.

162, FLEET-STREET, LONDON, and all Booksellers.

TO ADVERTISERS AND CORRESPONDENTS.

. In future all Advertisements and Communications for the Editor to be sent to

162, FLEET-STREET.

OUR MONTHLY PARTS.

Part 6 of THE ENGLISH MECHANIC, in coloured wrapper, is now ready.

Price 6d. only! Post free, 7d.

All back Nos. have been reprinted, and can be had direct from our Office, or through any bookseller.

TO ADVERTISERS.

As the ENGLISH MECHANIC addresses itself to the largest and most intelligent portion of the community, and is the only Paper of the kind established, it offers unusual advantages as an advertising medium.

SCALE FOR ADVERTISEMENTS:

	2 s. d.
Five Lines	0 3 0
Every additional Line (Nine Words) ...	0 6 0
Whole Page	8 0 0
Half Page	4 0 0
One column	3 0 0

Post-Office Orders to be made payable to GEORGE MADDICK, Fleet Street Branch.

All Advertisements should be sent to us not later than Friday.

The English Mechanic.

FRIDAY, OCTOBER 13TH, 1865.

THE SOCIAL SCIENCE CONGRESS.

FOLLOWING the flight of the British Association savants comes that of the Professors of Social Science, male and female—for here, at least, woman asserts her rights and lefts—who have this year chosen Sheffield for a temporary roost. Foremost now, as of old, where good is to be done, was Harry Brougham as President, who took up the thread where it was dropped last year, and lucidly expounded from the text, What has been done for the good of mankind, in Britain, during the past twelve months. From the Sacred Book to the humble pennyworth he travelled, taking in the ballot, extension of the suffrage, co-operation, savings banks, Government annuities, education, help for the helpless, prison discipline, law, logic—everything appertaining to social science was happily touched upon by the venerable, as indefatigable president; and though the bent head and feeble frame denoted that Time was doing his work upon this noble son of toil, yet it was not until after half an hour's reading that his lordship had to hand

over the finishing of his presidential task to Mr. Hastings; and then it was the wisdom of the ancient from the lips of the modern. It is not to be expected that we can give room to the address in full. Some extracts we may be able to give of more than usual interest; but our readers will doubtless possess themselves of the entire document, which is well worthy of preservation as a record of the progress made in the science in the "Congress year" last past.

There is one point we wish to see touched upon, and that is the giving of a percentage of profits by employers to the employed. It has been adopted in several large concerns, and with benefit doubtless to all concerned; it has the charm about it of the "family," and, if properly gone about, would do away with many of the heart-burnings which exist, and which have yet to run their bad race, and do damage in strikes and lockouts. It covers the whole ground nearly of the majority of disputes, and is well worth the attention of the employer class throughout the land. Some may call it nonsense and utopian. We don't; and dare be sworn to our opinion that the places in which this "share" system is carried out honestly and fraternally will know strikes no more.

We have spoken of the Congress in question as one in which the gentler sex can come out as strong as they like; doubtless, as we write, they are doing so as of yore—for, on anything on which their sweet lips may be privileged to open, they give tongue most fluently. We would suggest, however, their forming themselves into an independent association; it looks so, to be hanging on to a masculine affair! And then we could admire the fluency of the writers, and the soundness of their logic much better, and be far more able to see exactly where woman was made to shine.

The Association, we need scarcely say, has our best wishes, as it has those of every well-wisher of his country, including every man and boy among our subscribers.

CHEMICAL AND MECHANICAL OIL-TESTS.

THERE are, comparatively speaking, but few substances, the adulteration of which is so frequent, and so difficult to detect, as that of animal and vegetable oils and lubricants. We propose, therefore, to give a short account of the means employed for detecting the adulteration of lubricants with other oils, and also of the manner in which their qualities are usually ascertained.

The kind of oil used for adulterating other lubricants depends, of course, on the comparative price of oils. Thus, although rape oil and poppy oil are generally cheaper than olive oil, and hence are often used for adulterating the latter, yet a change in price has sometimes caused just the contrary adulteration to take place. But, generally, table olive is adulterated with poppy, sesame, or nut oil; olive oil for machinery, &c., with rape oil; rape oil with poppy, nut, linseed, and more frequently with whale or train oil; linseed oil very frequently with the coarser kinds of olive and rape oil; and sperm oil with nut oil.

The usual tests for oils and lubricants may be divided into chemical and mechanical tests.

The former at once show the kind of oil employed for adulteration, whilst the latter indicate this indirectly, by proving the physical qualities of the lubricant.

Chemical tests usually show the nature of an oil by inducing a peculiar colouration, or a change in consistency, or a rise in temperature.

A very explicit account of the striking effects produced by sulphuric, nitric, phosphoric acid, caustic, soda, on various oils, is given in an article by Mr. F. Grace Calvert, F.R.S., in the *Philosophical Magazine*, February, 1854, and reprinted in Ure's "Dictionary," and elsewhere. He states that one part, by bulk, of sulphuric acid having a specific gravity of 1.475, mixed with five of oil, shows, after 15 minutes, a very green colour if linseed or hempseed, and a red colour if a fish oil be present. By these means 10 per cent. of either of the first oils may be detected. As little as one part of fish oil in 1,000 parts of another oil may be discovered from the dark red to black colour imparted exclusively to fish oils, by mixing with 1-5th part of syrupy tri-hydrated phosphoric acid. Other very characteristic reactions are obtained by adding first nitric acid or aqua regia, and then caustic soda. For further details of these very extensive researches by Mr. Calvert, we refer to the above-mentioned publications.

A more easy test is the unvarying rise in temperature that takes place on the addition of one-

third of monohydrated sulphuric acid. This is the most concentrated form of the acid, and is obtained by distilling that of commerce.

Olive oil rises 68 degrees Fahr., poppy oil 126 degrees, and rape oil 100 degrees. With linseed oil the action is so powerful, that the monohydrated acid can only be used when mixed with 10 per cent of the acid of commerce. With this mixture of acids linseed oil rises 135° in temperature, whilst rape oil rises 68°, and olive about 50°.

Schneider detects rape oil in other oils by dissolving the oils in question in ether, and then thoroughly mixing with it 20 to 30 drops of a solution of nitrate of silver in alcohol. The mixture is left for a short time in a shady place, when, if much rape oil is present, the lower part turns brown, and, finally, black; with a smaller quantity on the other hand, a distinct brown colour appears after, at most, 12 hours.

Resin oil may be detected in other oils by adding 10 parts of ethylene alcohol, Sp. gr. 0.83, and shaking the mixture for about a quarter of an hour. The upper milky strata will then contain the resin dissolved, and, if filtered and cautiously evaporated, will leave the resin as residue.

A Frenchman, M. Hauecorne, has found binoxide of hydrogen, or oxygenated water, an excellent test for olive oil. By adding one-fourth of binoxide of hydrogen and shaking up the mixture pure olive oil turns applegreen; poppy oil, flesh coloured; sesame oil, bright red; and nut oil, milky and greyish yellow. He tested in this way 292 samples of French olive oil, and found one hundred adulterated with nut oil, six with sesame, and only one with poppy oil.

(To be continued.)

PHOTOGRAPHY.

SPLITTING OF COLLODION FILMS.—The Editor of the *American Journal of Photography*, in reprinting an article from the *Photographic News* on this subject, adds:—"A more frequent occasion of exfoliation than any of those above enumerated is the acid condition of the plate. If the plates have been treated with acid, any amount of washing in simple water will not remove the acid effect, when there is a tendency otherwise towards exfoliation. Any alkali neutralizes all the acid."

MEETINGS OF SOCIETIES.—We remind those of our readers concerned that the winter session of meetings of most of the societies will commence next month. The North London Meeting will be held at Myddleton Hall, and the South London Meeting at the City of London College.

PHOTOGRAPHS OF WELSH BARDS, &c.—At the Griffithdod just close to Aberystwyth, Mr. W. Geistdod received the first prize, a silver medal, for his series of photographic portraits of Welsh bards, minstrels, and literary, scientific, artistic, and other popular men.

STAINS IN PRINTS.—A correspondent of the *Photographic News*, who was recently troubled with peculiar stains of one shape on the back of his prints which extended to the front, informs us that he has found the cause in a japanned waiter, upon which the prints were laid to dry. We presume it had been japanned iron, and the japan had been removed in one place, thus staining the prints with iron. It often strikes us with surprise to witness little acts of carelessness of this kind, the source of numerous troubles which photographers thus voluntarily encounter.

SPLITTING OF THE FILM AND THE GELATINE DEVELOPER.—Another correspondent, signing "Kent," informs us that he has suffered from films splitting off where he has used the gelatino-iron developer but that a coating of dilute gum arabic before drying the plate prevents it. We cannot see any reason why this developer should produce such an effect, as its whole tendencies would seem to be in the opposite direction. If in the preparation of this developer, free sulphuric acid were left, it possibly might produce such a result; but if the developer be prepared properly, splitting of the film is most probably the result of an extraneous cause which chances to be present. See an interesting letter on this developer by Mr. Nelson K. Cherrill, in the present number.—*Photographic News*.

TRIAL OF THE NEW JERSEY FLYING MACHINE.—We are informed that the flying machine which has been in process of construction in Jersey City, and which has been incorrectly called the Government flying machine, as the Government had nothing to do with it, has been completed and tried. It of course failed, as everybody of any judgment knew that it would. They could not get it off the ground.—*Scientific American*.

LETTERS TO THE EDITOR

[We do not hold ourselves responsible for the opinions of our correspondents.]

LAPIDARY.

Sir,—Some of the following information may perhaps interest your correspondent "Lapidary." The manufacture of articles made of agate, cornelian, and similar stones, is principally carried on in a small district of Germany, adjoining Rhenish Prussia, and the Palatinate. The stones having been first chipped into pieces of a suitable size, are ground to the required form on circular stones, about 5 feet in diameter, revolving vertically, and driven by water-power. The various indentations are produced by suitable grooves and ridges, that are first cut on the grinders by a hard stone, generally a kind of graywacke. The lapidaries work in a horizontal posture, fast downwards, their chest being supported by a kind of inverted wooden saddle, placed in front of the grinders, and about two feet from the ground. In this position, and with the assistance of a foot-board, the workman can exert considerable pressure. Where perforations or very intricate forms occur in the pattern, recourse is had to the drill and lathe, assisted by diamond powder. The stones are finally polished upon wooden rollers, also furnished with suitable grooves, and smeared with tripoli powder and water. Sometimes the tripoli powder is moistened with sulphuric acid; but, if possible, this method is avoided, as the corrosive action of the acid sooner or later destroys the polish.

OUR SUBSCRIBERS NOTES AND QUERIES.

CEMENT.—Required for uniting cast-iron to glass.—Wm. HUDSON.

VELOCIPEDES.—Any recent work on the construction of these, or information how to proceed?—N. J. W.

CEMENT.—Required for uniting glass and wood?—MAGNETIC.

ELECTRIC SPARK.—Can I get the electric spark, or make the electro-magnet, from the magneto-electric machine?—J. NEWTON.

WORKING TOOLS.—Where to get a book giving a practical account of how to work with smiths' and engineers' handtools—such as the scraper, file, chisel, &c.; also, turning and forging small articles.—W. GRAY.

CEMENT.—A quick drying, fast-setting cement to combine flannel and iron, which has to do a deal of hard work as a roller.—B. Y.

APPRENTICE.—Where can I apprentice or article myself as an engineer? I am 19, and have been in the trade between three and four years.—HALF MECHANIC.

FANS.—At what speed should an eccentric fan revolve to exhaust heated air or dust along a pipe? What should be area of exit pipe, and what the power necessary to drive fan of following dimensions:—Circumference (measuring round the extreme end of leaves, 5 in number) about 6 ft. 9 in.; diameter to end of leaves, 3 ft. 2½ in.; size of leaves, 5 in. x 9 in.—W. LEWIS.

KEBOSSNE.—Can any one tell me whence and how this is obtained?—ALPHA.

MAROGANT DYE, &c.—Wanted, a recipe for making mahogany dye; also, one for preparing gold leaf for illuminating paintings, &c.—Z. Y. X.

BLACKING SLIDES.—What is the dead black, and how used, for astronomical slides in the magic lantern?—R. B. JORDAN.

TOOLS FOR SPRINGS.—Wanted, to know the method of making tools for turning up spiral springs, the size for each number of wire, and how used?—A LIVERPOOL WATCH-MAKER.

CEMENT, &c.—What kind of cement will fasten wood to metal to withstand action of heat? Can I dissolve shellac without spirit? Can plaster of Paris be made to withstand moderate heat, and how? If not, what plastic substance will?—J. J.

ELECTRIC COIL.—Can I make a coil of the following description to work:—The core is ¼ inch thick, 5 inches long; the brass tube to draw out has 102° marked on it; contact breaker is on the side of the disc of wood? I have ½ lb. No. 16 cotton-covered copper wire, and ½ lb. No. 23 do.—G. TOLMAN.

BOILER PROPORTIONS.—The best size of boiler (in cubic feet) for a cylinder 8 inch stroke, and 3 inch diameter, at a pressure of 30 lbs.—W. D. WANSBROUGH.

GELATINE, &c.—How are the gelatine "motto" cards manufactured? also, artificial slates and parchment?—AARON LYD.

BLEACHING RESIN.—How to bleach resin white.—A. L. WILLIS'S MECHANICS.—Who is the publisher, and what is the price, of "Willis on Mechanics"?—T. HARRISON.

TRUE FACE-PLATE.—How can I make a perfectly true face-plate 18x24 in.? Also, how to test oil while purchasing it, so as to see if it be non-clogging?—D'AUNOISE.

CYLINDER.—What should be the size of a high-pressure cylinder, for economy and power? The low pressure is 20 in. in diameter, and works at 60 lb. pressure; how many horse power would it be called?—W. J. J.

ELECTRICITY.—What would be the price of a small electro-magnetic machine—single or double magnet—for experiments in a lecture-room? Where could I get carbons and batteries, and their prices?—J. W. MERTHER.

PARAFFIN BURNERS.—How to fasten burners on paraffin lamps?—SUBSCRIBER.

JAPANNING.—The best way to japan bull's-eye lamps, and what kind of Japan to use?—A SUBSCRIBER.

POLISHING JAPANNED WORK.—How best to do it?—J. JEFFERY.

[Such as are baked in ovens, for the evaporation of the solvent of the varnish, are first forwarded with pumice-stone powder applied with water, or list, or flannel; 2nd, they are polished either with rotten-stone, or putty powder and oil, also on flannel; and, with the dry hand and rotten-stone.]

PREPARING SILK.—What is the art of preparing silk or fancy stuffs for covering fans and fancy goods?—JOHN JEFFERY.

DIE COUNTERPART.—How to make a counterpart for a steel die for producing stamped brass ornaments in a fly press in large quantities?—AMATEUR DIE SINKER.

[We have seen a fair one produced in lead, taken from the other, well hooped in.]

SHOEMAKER'S BENCH.—Is there a patent bench for shoemaker's to stand to work at? If so, who is the patentee, and where may one be had? Also the best sewing machine for shoe making in general use, and price?—B. M. T.

VELOCIPEDE.—Will any one tell "J. B. H." where he can get information how to set about making one?

MICROSCOPE CONDENSER.—Can the inventor tell me the expense of the condenser described by him in No. 6, and where it may be bought?—W. O.

CARDBOARD.—Is there a machine in existence for pasting cardboard (single sheets or otherwise), and if so, where can I get one?—CARD MAKER.

"PINNING" OF FILES.—Wanted, a remedy for the "pinning" of files, where to procure fine plaster of Paris, a good handy book on turning in iron and brass, &c.—POSTULATA.

SMALL CASTINGS.—How can I melt small quantities of iron for casting small pieces of machinery? Also, a description of the tools necessary in the operation.—B. L. B.

ELECTRO-MAGNET.—What size of wire is required for making one, to give strong shocks, and how much required?—J. D. E.

CASE HARDENING.—The best mode for case hardening angle iron; also, how to calculate the wheels for screw cutting with the slide rule?—J. D. E.

[We described a method of case hardening, both large and small work, some time ago. There is a turner's and fitter's pocket-book for calculating the change wheels for screws on a turning lathe, by J. Le Noce, price 6d., sold by Spon. There is also the book advertised in our columns by James Martin.]

INDUCTION COIL.—Having paid over £6 for materials for an induction coil giving long sparks, constructed it by binding the secondary as cotton on a bobbin, and insulating with gutta percha, but having failed to get a satisfactory result; perhaps some of your expert correspondents in electricity could tell me of some plan of construction, so that in the event of a break in the passage of the secondary current through some miles of wire, it may be corrected without uncoiling all the wire, and having to rewind it.—W. O.

ROPS FOR TURRET CLOCKS.—What is the best wire rope for turret clocks, copper or steel, the size to carry a 19 stone weight, and the best place to purchase them?—THOMAS TOMLIN.

CYLINDER.—What size cylinder will a boiler 3 feet long, and 20 inches diameter, of square end form, drive? Also, any easy rule to find the size of cylinder required, the full dimension of boiler being given.—JOHN JAMES.

TO HARDEN COFFEE MILLS.

"A. Smith" (No. 27, p. 8), does not say what particular preparation of potash, and as there are a great number, perhaps he will be so kind as to give the precise kind, or his information as it stands at present is useless, for it would be no use to go into a shop and ask for 3d. worth of potash. GIVE AND TAKE.

VEHICLE FOR COLOUR.

Could you kindly give me shellac and borax, say, to a pint of water, the time of boiling, and also the kind of shellac, if so, you will greatly oblige. GIVE AND TAKE.

[The correspondent who forwarded the recipe, will, perhaps forward full directions for the benefit of "Give and Take," and other subscribers.—Ed. E. M.]

PEROXIDE OF BARIUM.

Sir,—In answer to "Chemicus" (Derby), Binocide or Peroxide of Barium Ba (O₂ = 10.6), a greyish powder. It is prepared by passing dry oxygen gas slowly over anhydrous barytes, carefully prepared from the nitrate in a hard glass tube, or by sprinkling chloride of potash in small portions over barytes, at a low red heat in a platinum crucible, and washing out the chloride of potassium with water, the hydrated binocide remaining (Liebig).

ALPHA.

PETROLEUM, A STEAM FUEL.

Sir,—A paragraph appeared lately in a daily paper respecting petroleum as a steam fuel. Whale oil is mentioned in it as being a hydro-carbon. It should have been shale oil. The manufacture of shale and coal is destined to become one of the principal branches of industry in this country; their excellence have all driven out the American petroleum. The public appear to know very little respecting them. These British hydro-carbons are only about half the price of the American. The best are of specific gravities from 850° and 900°, water being taken as the standard at 1,000°; in using them as steam fuel their specific gravity is not, I believe, of much importance. The manufacturers have a coal that produces good crude oil, unfit for refiners, but which would do for fuel. This would be at about one third the price of the American. As a steam fuel they are far more powerful than coal, and for marine engines will, before any very long period, entirely supersede it. C. J. RICHARDSON.

HEATING GREENHOUSES.

Sir,—In reply to "Ironmonger," to heat a forcing house to about 80 degrees Fahrenheit above surrounding temperatures:—Rule:—Multiply the length of the house in feet by the width, and this product by two thirds of the greatest height, and divide this by 10, which will give the length of 2 in. hot water pipes; for 3 in. pipe, divide by 14; for 4 in. ditto, divide by 19. Example: required the length of 3 in. pipe to heat a

forcing house to 80 degrees above surrounding temperature. Size, 100 feet long by 30 feet wide, and 15 high at back; $10 \times 30 = 3000 \times 10 (=3) = 30,000 \div 14 = 2,142$ (feet required.) The tube to heat a greenhouse is much the same, only divide by 15 for 2 in.; by 22 for 3 in.; by 23 for 4 in. Example: $50 \times 20 = 1,000 \times 8 (=3) = 8,000 \div 28 = 285$ feet of 4 in. pipe. There are a great many kinds of boilers now in use, and all have their special attractions, but the one I should recommend as the most serviceable is an upright tubular boiler made by Lynch White, of London, where you can also be supplied with all kinds of fittings, pipes, &c. The usual means of making the joints is with tin cement or red lead, and spun yarn, and I should recommend the latter as preferable, having had considerable experience in the uses of both. W. H. WALLACE.

BOBING SMALL CYLINDERS.

Sir,—In answer to "J. H. J." in No. 27, the best way to bore small cylinders is to fix a piece of hard wood to the face plate or chuck, and bore out the wood so as to allow the cylinder to be driven up tight, then take a roughing, cut up the cylinder with an ordinary boring tool within 1-16th of an inch of the required size, then for a nice smooth finish use such a tool as represented in the sketch.

The pieces of hard wood are screwed from one to the other, as represented at A, and a gutter cut up, as at B in Fig. 3, to allow for clearance. JOHN SWIFT.

NEGATIVE SLIP.

Sir,—I noticed an elaborate report in the *Times* of the trial trip of the *Bellerophon*. The writer says a great deal about "negative slip," but does not attempt to account for it.

This I understand to mean, that the vessel is actually going through the water faster than her screw is propelling her—in other words, that she is dragging the screw through the water. In the case of the *Bellerophon*, it is said that she was overrunning her screw to the extent of a mile and a half per hour.

It seems to me very strange that this phenomenon has never been satisfactorily accounted for, and I hope that your correspondents may be induced to broach some theory that will account for it. W. G. W.

MARINE GLUE.

Sir,—In answer to "J. Bunney," Aug. 18th,—Marine glue is made in the following manner:—

Make a solution of good caoutchouc with coal naphtha in the proportion of 1 lb of caoutchouc to five gallons of naphtha. In about twelve days it will be dissolved to the consistency of cream, when two parts of shellac should be added to one of the solution; it should then be heated, and stirred till well amalgamated.

I should think that this glue would also suit young "Warwick," whose query is in your magazine of the 11th of August. J. D. E.

[See "Notes and Queries."]

THE ATLANTIC CABLE.

Sir,—To raise the cable by under running, I propose to construct a hollow metal buoy, of a cigar or fish shape, filled with compressed air, and surmounting a strong steel Y-shaped frame, carrying a deeply-grooved gun metal sheave for the cable to run in. On the buoy shall be a hoop, or

A, cable; B, section of buoy.

band, carrying two eyes, for the insertion of lifting chains or ropes, the submerged buoy to be propelled by two steamers, till the whereabouts of the broken end be nearly arrived at, the vessels to be then joined by the *Great Eastern*, whose immense power and appliances would materially assist the actual force; and the end once happily lifted, the "paying-out" would then be of a different character and results to the paying-out of the unfortunate shareholders at present. EDMUND DEARY, Engineer, Maldon.

ALUMINIUM BRONZE.

Sir,—"Neophyte," in No. 23, may obtain this by strongly heating in a crucible pure alumina, finely-powdered charcoal, and a very pure copper, finely divided—that from Lake Superior ore is preferred. The strength of the alloy composed of copper, 90 parts, and aluminium 10 parts, is, per square inch, tenacity, 73,185 lbs., or 1185 lbs. more than the average capacity of cast-steel; resistance to compression, 132,416 lbs., Sp. gr. 7.689. J. H. M.

CYLINDER AND BOILER.

Sir,—Your correspondent "Machina vi Vaporis" makes enquiry, what size boiler he requires for an engine whose cylinder is 2 1/2 inch bore, 5 inch long, and powerful enough to drive a lathe.

I have a wrought close-range boiler, 1/2 inch plate, 11 inches high, 6 inches wide, 23 inches long, and 10 inches wide, which I have used for driving a lathe with a cylinder about the size of M. V.'s, with steam at 15 lbs. per square inch.

I wish to dispose of it, and if it will suit M. vi V., it can be seen at Messrs. Willey and Ranger's, ironmongers, Upper-street, Islington. JAMES STOCKBRIDGE.

LATHE.

Sir,—In reply to "Sytematic's" enquiry,—He may turn a crank by placing a strong carrier at each end of his shaft, pitching his centres in the carriers, and taking care to block up the ends by a shore from the crank on each side. If necessary, place a counterpoise to balance the weight of the shaft. The bearings on the shaft may be turned in the ordinary way, only take care to place a blocking in the crank, to prevent its breaking with the pressure on the centres.

Can any of your valuable correspondents tell me of any machinery that has been invented for strengthening iron wire from the coil other than setting with a hammer? I have some 21 lengths of 14 wire to get up straight, and I find the setting rather tedious, and they are too rigid to get straight by pulling. NIMROD.

ELECTRO-MAGNETIC MACHINE.

Sir,—Being simply a mechanic, and not an electrician, I may say something nonsensical if I venture out of my proper sphere.

I will, however, give you an outline of the mechanical part of an electro-magnetic engine, which I have been pondering for some time.

Z is the sole plate carrying the wooden disc V, and the crank shaft y.

W is a wheel-mounted on crank pin, and furnished with nine armatures.

On V are placed twelve electro magnets, a, b, c, d, &c. The wheel W and the disc V are supplied with teeth, to cause the armatures to fall direct on the magnets.

On the shaft y is to be placed a barrel, with twelve prongs, to strike keys in the barrel-organ fashion, so as to make the communication between the battery and the magnets in succession.

The shaft Y is to be furnished with a fly-wheel, loaded so as to counterbalance the wheel W.

Such is my idea of the mechanical part of the business. Our electrical friends will, I hope, be able to supply the he rest. ROBERT SLOANE (Glasgow).

MAKING HOLES IN GLASS.

Sir,—By using camphor and oil of turpentine a hole can be bored in glass with a 3-cornered drill; also, a watch-spring made into a saw will saw flat glass, and a female screw can be made in plate glass. J. S.

[We answered an inquiry of the nature of the one you make immediately it was sent us, under heading "J. Stewart."]

COMPRESSION FAUCET.

Sir,—In the concluding number of the first volume, the beautiful illustrated description of a compression faucet agrees, in all particulars, with one invented some thirty years ago by John and Robert Heart, of this city. I fixed them on for the inventors as kitchen taps, and to supply the water-closet cisterns in a new property, Bath-street.

They are particularly well adapted for street wells, for which purpose a rood many are used. J. HILLS, Glasgow, Oct. 1st, 1865.

ARMOUR PLATES.

Sir,—S. E. E. M." (No. 15) may submit his plans to the Under-Secretary of War, Pall-Mall, and he will probably receive—thanks. J. H. M.

DEPOSITING ALUMINIUM.

Sir,—In reply to "J. R." (No. 15), he will find several patents:—Jurist's is No. 1183, Dec. 28, 1852; Thomas and Tilley's, No. 2756, Dec. 6, 1855. The latter dissolve hydrate of alumina in a solution of cyanide of potassium by boiling. This is filtered when cool, and a bag of alumina suspended in solution. J. H. M.

INDIAN INK.

Sir,—In answer of "S. F. F.," this is made from horse-beans, or from the kernels of the stones of apricots. Either is burnt in an oven till perfectly black, then ground to a fine powder, and made into a paste with a solution of gum arabic. It is then formed into long rectangular cakes. J. H. M.

TEST FOR COIN.

If "James Ward" will try the following, I think it will suit his purpose well. Get a thin flat piece of zinc about the size of a shilling, and place the gold or silver coin on it, then put the two together into his mouth; if the coin be good, it will have a very peculiar taste, but if spurious, this will not take place.

Or, if the coin be wetted and a piece of lunar caustic be rubbed on it, if good no change takes place, but if spurious then it becomes quite black. ISAAC K. CLATTON.

POROUS POTS.

In "Watt's Electro Metallurgy," Weale's series, 1s. 6d., a piece of ox gullet or windpipe is recommended as a substitute for the earthenware pot, and I have often wondered that no one has mentioned it before. I have never used it myself; I shall try it the next time I have occasion to use a battery, as my experience of the earthen pots is anything but satisfactory. GIVE AND TAKE.

MICROSCOPY.

A new dissecting microscope has been devised by Dr. Lawson, and manufactured for him by Mr. Charles Collins. It is of the class of simple microscopes; but is binocular, the lenses being semi-prismatic convex ones. The powers do not exceed six diameters; but Dr. Lawson considers that in the dissection of the lower animals such powers—when binocular—possess the following advantages over the ordinary dissecting lenses:—1st. That an abundance of room is left between the lens and the object, so as to admit of freedom of action of the operator's hands; 2nd. That the object may be easily and well illuminated by means of the "condenser;" and 3rd. That several structures situate at different levels are brought simultaneously into view. The stage of Dr. Lawson's instrument consists of an oblong trough of gutta-percha, in which small animals intended for dissection can be pinned under water. In the centre of this trough is inserted a small disc of glass, through which, from a mirror placed below the stage, a flood of light can be thrown upon transparent structures. Two arm-rests draw out on each side of the microscope, on which the wrists can be placed when the observer is at work. The upper and front portions of the case unfold upon the table, and display a series of scalpels, needles, scissors, &c., necessary for the dissection of animal tissues. When closed, the new binocular presents the appearance of an oblong mahogany box, about six inches long by three and a half wide. Its magnifying power is low; but this is more than compensated for by the relief which is given to the object under view, and the large amount of penetration which the glasses possess.

EMIGRATION IN THE IRON AND COAL DISTRICTS.

During the past two years, as has been noticed in the public journals, there has been a continual drain of emigrants from the iron and coal districts of South Wales, the great majority of them leaving for the States. Such was the drain at one time among the working population that a positive scarcity of hands was experienced at many of the works, and considerable inconvenience and loss were the result to employers. Since the close of the American war however, the emigration movement has been gradually checked, and, in fact, a good number of the emigrants have returned to the mother country, and they give a deplorable account of the state of the labour market in the States. The warnings that appeared from time to time in the daily papers have thus been verified, and now, when it is too late, many of the emigrants regret that they ever left the land of their birth. There is no doubt that a higher rate of wages is paid in America, but the depreciation in paper money and the dearness of all the staple articles of food reduce the earnings so must that a working man is, after all, better off in the industrial districts of Great Britain.

SMALL ARMS MANUFACTURE OF BIRMINGHAM.

By Mr. J. D. GOODMAN.*

The subject I have selected for elucidation is "The Statistics of the Small Arms Manufacture of Birmingham"—and that it is an important one to Birmingham may be considered from the fact that the workmen employed are estimated to number 7,340. Of these 3,420 are engaged in producing the materials, the barrel employing 700, the lock 1,200, the bayonet 500, and so on. Setting up these materials into guns employs 3,920 men. Of these the three chief branches are the stockers, screwers, and finishers. Each of these branches with its sub-branches is estimated to employ 1,000 men. The stocker lets the barrel and lock into the stock, and roughly shapes the stock. The screwer lets in the furniture and remaining part of the gun, and further shapes the stock. The finisher takes the gun to pieces, and distributes the several parts to the browner of the barrel, the polisher, the engraver, &c., and when they are returned he puts the gun together, and finally adjusts the several parts. The out-working system leads to the employment of a considerable number of young boys, who are employed mainly in carrying the work from one to another as it passes through its several stages. No very correct estimate can be given of the rate of wages earned by the workmen in the gun trade. With very few exceptions the work is paid for by the piece, and the rate varies considerably with the demand. During the past ten years there is little doubt but that the wages earned in this trade have probably exceeded those in any other. Several branches require very high skill, and the remuneration is in proportion; for instance, barrel boring and setting, stocking, rifling, lock filing, &c. A judgment can be formed of the delicacy of workmanship required in the first of these branches when it is stated that a military barrel has to be bored with such truth that it must receive a plug measuring 577 thousandths of an inch, and is condemned as useless if it take one of 580. A workman in this branch in full employment has frequently been known to earn his 5s. to 6s. a week. It is a very common practice in many of the branches for a workman to employ several assistants, whether working in the factory of his employer or as an out-worker. Such men, while paying those under them at the rate of 5s. to 10s. for boys, and adults 15s. to 25s. per week, will take for their own share several pounds. A workman is held to be an inferior hand who in any of the skilled branches cannot earn single-handed, when work is at all brisk, 30s. per week. The Birmingham gunmakers have long been aware that a more extensive use must be made of the advantages which they possess, and this has led to the erection in Birmingham of an establishment for the manufacture of guns by machinery on the interchangeable principle. We must give America credit for the introduction of this system. It was at once that it was brought into this country. The factory of the Birmingham Small Arms Company is now in working operation. The system is there carried out in its full integrity. It has been planned on a scale to produce 1,000 guns per week. There are upwards of 300 machines at work, but at present it has not reached its full power. The number of guns now made there is about 500 per week. From a return published of the number of barrels made for the Government in the years 1804 to 1815 the total was 3,037,644, or an average number of 2,531,137 annually. In 1804 the number produced was 80,000. It steadily increased up to 1813, when it reached 490,000 in that one year made for the Board of Ordnance alone. During this period Birmingham produced barrels and other materials for the India Company, amounting to a million. This makes the total number of arms made in the 12 years somewhat over four millions, or 1,074 per working day. A large number of these materials, manufactured in Birmingham, were made up into guns by the London gunmakers. To verify the traditional "gun a minute," said to have been the production of Birmingham during this war, we require 1,440 guns per day, or 525,000 per year. For this we must confine ourselves to the two highest years, 1812 and 1813, which produced respectively, including the India Company's supply, 381,682 and 654,450. It will be instructive to compare with the results now given the production of the French Government during the same period. The information is obtained from returns published in 1822 by M. Dupin, a field officer in the French service. During the years 1802 and 1814, a period of 13 years, the arms manufactured by France numbered 2,456,257, or about 200,000 annually. This number gives us

for every working day 604 guns. The number made in England, it will be recollected, being 1,074 per working day. At this time, it must be borne in mind that France had at her command the resources of Liege and Turin, in addition to her own. St. Etienne, the most important seat of the arms manufacture in France, supplied 754,000, while Liege produced 279,900, and Turin 107,000. Seven other towns supplied the remainder. The total number of guns proved in the period from 1859 to 1864 was 6,116,305. Of this number there were proved at the Birmingham trade proof house, 3,277,815; at the Government proof house at Birmingham, 978,249 (these last represent military guns made for the English service); at the London proof house, 1,325,139; and at the Enfield factory, 505,102. The Enfield factory has only been in operation seven years. The average annual production will thus be:—Birmingham trade proof house, 327,781; Birmingham Government proof house, 97,824; London trade proof house, 135,513; Enfield proof house, 72,154; making a total annual production for the whole of England of 633,272. From the returns I have in my possession, I have drawn out as accurately as I possibly can the number of arms manufactured in Birmingham and elsewhere for the Americans during the last four years. The first shot was fired at Fort Sumter on the 12th of September, 1861. On the 9th May following five purchasers of arms, some commissioned by different Northern States, others private speculators, arrived in Birmingham. Each had so well kept secret the object of his mission that when they found themselves all engaged in Birmingham on the same errand they suspected each other purchasing for the enemy, and their anxiety was increased accordingly, to secure the few thousand arms that were then in store in Birmingham. The few in hand were at once shipped off, and large orders were given, which continued to occupy the trade at their full power with one interval till March, 1863. The interval I allude to was on the occurrence of the Trent affair, in November, 1861, which led to an embargo being laid on the export of arms on December 4, 1861. This embargo was removed early in 1862. On the removal of the embargo one steamer took out from Southampton no less than about 40,000 rifles to New York. The trade worked at its full power, straining every nerve till, I find by the return of the Birmingham proof house, that in one month, the month of October, 1863, 60,343 rifle barrels were proved, being very few short of 2,000 per day from Birmingham alone, a number altogether unprecedented in the history of the trade. At that time the supplies produced in America at the Springfield Armoury, and elsewhere, began to tell upon the demand. We still find, however, that the numbers were 40,000 to 50,000 per month till March, 1863. They then fell to 14,000 per month, till in September, 1863, the Northern demand ceased altogether. Without notice the orders were suspended, and guns that had been sent over were even returned to this country. The United States Government found at that time their factories were equal to supply the whole demand. From the proof-house returns I obtain the following numbers, showing the extent of the supply of arms from this country to America:—Birmingham supplied 682,534; London, 344,802; making a total number of Enfield rifles sent to America of 1,027,336. The price of the arms manufactured by the English trade for Government use he estimated at £3. Data were given of the number of guns made in Belgium and England, and as to the future the paper said:—"It is manifest that the Birmingham gun trade must be on the alert if it is to maintain its ground. To contend against the cheap labour of Liege is not an easy task. The establishment of the machine factory, we hope, is a step in the right direction. It will secure for the town the trade in the highest class of military work, which otherwise would have gone to our competitors. Excessive prices for labour are still paid in certain branches of the work, particularly when sudden pressure comes upon the trade. A more uniform rate of wages would benefit all parties, and the master would feel more confidence in tendering for contracts at moderate rates, and the workmen would secure more regular employment. I hope the facts now produced, and which will subsequently be given more in detail, will serve to call the attention of the trade to points so closely affecting its future progress and well doing."

DR. DRAPER, of New York, has succeeded in taking a photograph of the moon 40 in. in diameter.

THE magnesium light is found to be sufficiently active to determine the combination of hydrogen and chlorine.

THE COAL FIELDS OF THE MIDLAND COUNTIES.*

Both the extension and duration of the coal-field are questions open to a very great difference of opinion. If the extent was limited to the at present explored portion of the district the duration might be tolerably accurately calculated, as all the coals that can be possibly reckoned upon in a descending order in this coal-field have long since been discovered. It is to the confines of the present coal-field, then, that any hopes for fresh supplies can be looked for, and it is a very interesting fact that on all roes of the coal-field explorations are being most successfully carried on, with, perhaps, the exception of the eastern boundary on Birmingham side. But the coal depth at which the thick coal has been worked in the neighbourhood of West Bromwich is about 400 yards in depth. The result of operations now going on in other portions of the coal-field is, however, being looked forward to with great interest, as affording sufficient evidence to warrant an attempt to reach the coal in the neighbourhood of Smethwick and Harborne. During the last ten years, more especially the last five years, a great number of new winning have been made on north end or Cannock Chase district, as also on the north-east at Aldridge, and at Hanley and other places; but probably the most important recent trial sinkings are those on the south end of the coal-field in the neighbourhood of Halesowen, Congreaves, Cradley Park, and Waseel-grove. In the event of the one at Halesowen and that of Waseel-grove discovering the thick coal, both of which look very promising, and are now sunk to about half-way to the coal, more than 4,000 acres of the thick seam may be considered proved, and this assurance will no doubt give a fresh impetus to additional research even further south than those now in operation. Very rapid strides are now being made in developing the thin seams over several thousand acres of previously unexplored ground on Cannock Chase, which is now being intersected by canals and railways in every direction. These thin seams are, however, exhausted as compared with the thick coal seam. To attempt to estimate the probable duration of the Staffordshire coal-field, whilst these somewhat important recent additions are being added to it, would be impossible; but it may be observed that such additions are not keeping pace with the enormous consumption and consequent rapid destruction of the parent portion of the coal-field. In a very valuable paper read by Mr. Matthews, in August, 1860, after obtaining the best evidence upon the subject, he estimated the duration of all parts of the coal-field at an average of about forty years from that period. There can be no doubt but that in one-half that number of years a very large portion of the earlier developed part of the coal-field will be totally and for ever exhausted; as, for instance, the mines in the neighbourhood of Bilston, Coseley, Tipton, Wednesbury, Oldbury, Westbromwich, Breckmore, and Brierley-hill are being fast worked out, and in twenty years hence will be well-nigh totally exhausted.

THE TIN AND JAPAN TRADES AT BILSTON.

Bilston is distinguished for the production of japanned and tin ware, similar in kind, but rather lower in quality, than that manufactured in Wolverhampton. Trays and waiters are made in great quantities, one firm making 600 sets of trays (three forming a set) every month, and not less than 100 gross of waiters per week. These articles are all stamped, and are of a great variety of shapes, there being about 2,000 distinct patterns, either in shape or ornament. The most prevailing shapes, however, are convex, Gothic, and oval, the former having perhaps the greatest sale. They are japanned, and afterwards ornamented either with paint or gold leaf. Those for export trade are embellished in accordance with the prevailing taste of different markets, and it is a curious and interesting study to notice the varied styles of art most popular. For Brazil the most saleable ornament is a shield, surmounted by a crown, and encircled with coffee berries. For South America bright gaudy colours are mostly in demand. In Spain the most favourite ornament is the representation of a bird. It is not necessary that the artist should study the rules of natural history, so that the bird have brilliant coloured feathers. Red, blue, and yellow, are the most esteemed by the Spaniards, and the Bilston artists present them with more extraordinary specimens of ornithology than Buffon or Goldsmith ever dreamt of.

NEW CHUCK FOR WOOD OR METAL.

Messrs. Editors (writes a correspondent of the *Scientific American*). Several kinds of chucks are employed for holding work between two centres; for wood, prong chucks or square hold are the most common; for metal, dogs are usually employed; the disadvantage of the above-named chucks for wood is, that the work frequently gets out of centre, when any pressure is used, and it cannot be taken on and off for examination without a risk of missing the centre, when replaced.

The disadvantage in using dogs, when turning metal, is the necessity of turning the work end for end, which requires the dogs to be shifted—when you wish to turn a cylinder, for instance, or when you wish to file a cylinder on the lathe; and another nuisance of dogs is, the catching of the tool or fingers against the projecting points of the dogs.

To obviate these inconveniences, I invented a very simple contrivance for holding work between two centres, which is equally applicable to wood or any kind of metal, and the same chuck will hold as firm as a vice a piece of wood or metal half an inch or even twelve inches in diameter. It, moreover, enables the tool of the slide rest, or the hand tool, to pass over the whole length of the work, without turning it end for end; and you can take the work off fifty times and replace it with perfect accuracy.

This chuck is merely a short cylinder of brass or of iron, which screws on to the lathe head with a steel point projecting from the centre of the other end, and three steel points at a short distance from this centre point, but not projecting quite as far out. These three points are equidistant from each other and from the centre point. The projection is about one-quarter of an inch, more or less, according to the nature of the work.

Fig. 1 show the face of the chuck with four points projecting. Fig. 2 shows a side view of the chuck.

FIG. 1.

FIG. 2.

To make this chuck I drill four holes in the face of it, each about half an inch deep, with a drill corresponding with any size of Stubb's steel wire—one of my chucks is drilled to No. 15, another to 22. I then cut off three pieces of Stubb's steel wire of one size smaller than the holes drilled, and point each one on the lathe, and dip the blunt ends into melted tin after dipping them into muriate of zinc. I heat the chuck on a stove, drop into each hole a little muriate of zinc, and then, with a pair of pincers, put in the steel wires, with the points outward; and when cold the chuck is finished. To use it, drill a centre hole in each end of the work to be turned, with the same drill employed to make the four holes; put the centre point of the chuck into the centre hole of the work, give it a tap with a mallet, and you will have three marks which will enable you to drill the other three holes in the work, with the same drill.

These four points, when inserted into the piece to be turned, and when the other end of the piece is held by the point of the puppet head of the lathe, will keep it as firm as if held by a vice, and it can be taken off and replaced without regard to which of the three outer points is inserted—for if drilled equidistant, all will fit the work.

A bar of metal, in which the four holes have been drilled, can be used up until within one-fourth of an inch of the end, and once the chucks are made and the proper drill at hand, it will be found as easy to mark and drill the four holes in the work as to adjust and screw up a pair of dogs, especially if you have several pieces of metal or hard wood to turn.

BUFFON combined plane glass mirrors only 6in. by 8in., and with 40 set on fire a tarred beech plank, 66ft. distant; with 98 at 126ft., with 112 at 138ft., with 168 at 200ft.; and he melted metals at 30ft. or 40ft.

MEERORS and falling stars have been found by eminent astronomers to be minute planetary bodies. When visible they pass at a height of from fifty-two to seventy-three miles above the surface of the earth.

RICE AND EVERED'S TUBE SHEET CUTTER.

This tool is intended to bore the holes for flues or tubes, in the tube plates of locomotive or tubular boilers. It is designed to do extra good work, and is especially valuable where the tubes are close together, since, in plates that have a hole punched or drilled in them to guide the end of the old tool commonly used, there is great danger of the drill running out, or the holes being badly punched by careless persons. With this tool the work must always be first-class. The hole will be true with the centre, and, if the marker lays the sheet off properly, the tube plate will be a fac-simile of the draughtman's projection in the drawing room.

In detail, this tool is simply a steel shank, A, with a sleeve, B. This sleeve slides, but does not turn on the spindle, being held by the feather, C. There is a thread on the sleeve which fits the hollow shank of

FIG. 1.

FIG. 2.

the hand wheel, D; when the wheel is turned, therefore, the sleeve is drawn up or down.

The lowest end of the sleeve is formed into a socket, E, in which the cutters, F, are held, and there is a centre, G, in the spindle, which works in the centre punch mark in the work. The hand wheel rest on a collar, H, and is kept from rising by a nut, I, with a left-handed thread. There is a bracket, J, on the table which supports the sheet to be drilled. These are the details.

The inventors and manufacturers say:

"The object of this tool is to save time in drilling tube sheets, by not having to drill the centre hole, which is now either drilled or punched previously to cutting out the full-sized hole, thus saving one handling of the plates. There is also a saving of scrap iron, as thinner cutters can be used, and the centre hole is not cut out, but all left in a solid piece. This is no small item where much of this work is done; the difference in scrap iron would soon pay for the tool.

It also takes less power to cut than with thick cutters. Another important item is the saving of cutters; these cutters are not half so liable to be broken as those in common use. The reason that these cutters are not so liable to break is, that there is no slack motion to the cutters; they cannot go through or draw themselves into the sheet any faster than the natural feed. All the holes must be, with this tool, cut exactly true with the centre punch mark; there is no chance for the drill to run; and where holes are drilled pretty close together, this is also a very important object—locomotive builders, especially, would find this a great help to them in doing good work. It is necessary to have a good solid drilling machine, in using this tool, in order to give the best results. We have used this tool for nearly a year, and are better satisfied with it every day, and have often cut at the rate of 600 holes two inches diameter in five-sixteenths iron, per day of ten hours. The patent for whole States is for sale. We can also manufacture the tools for sale, and have some on hand."

This invention was patented through the Scientific American Patent Agency on May 30, 1865, by D. E. Rice and William Evered, of Detroit, Michigan.

ELECTRICITY.

THE SPECTRUM OF THE ELECTRIC SPARK.—The indefatigable Abbe Laborde has made some important observations upon the spectrum of lightning, which are reported in our contemporary, *The Reader*. When the flash appears directly before the spectro-scope, as he has been fortunate enough to see it three or four times, the bright lines of which the spectrum is composed are very numerous and well marked. More often the lightning is seen reflected from the clouds in its spectrum, the bright lines are still visible, and increase in number as the flash is more vivid. They are all of a dull white or lead colour, but one among them is always more apparent than the others, and is sometimes seen alone. This line is not far from Fraunhofer's line E. When, however, the flash appears at a great distance, or is seen through a thickness of cloud, almost all the bright lines disappear, and the spectrum is nearly continuous. The appearance is similar to that observed when several unpolished pieces of glass are placed between a source of light and the spectro-scope. The Abbe remarks that, when lightning is observed by the spectro-scope, it is therefore important to note the degree of visibility of the bright lines it gives, for the thickness and opacity of clouds can vary them greatly.

NEW MODE OF EMPLOYING BUNSEN'S BATTERY.—M. Duchemin not long since announced to the Academy of Sciences that in Bunsen's battery the nitric acid could be replaced by perchloride of iron, and the sulphuric acid by a solution of common salt. He has now stated that by substituting crude chloride of potassium for the common salt, the electro-motive force of this battery is increased, and its caloric effects intensified; the electric light being easily produced when the chloride of potassium is employed, instead of chloride of sodium.

HOW TO MAKE AN INTERMITTENT FOUNTAIN.—M. l'Abbe Laborde, writing to *Les Mondes*, describes a simple apparatus for producing an intermittent fountain. It consists of an inverted flask fitted with a cork, through which pass two tubes of unequal length. The longer reaches nearly to the bottom of the flask, and outside has a length of some twenty inches. The shorter tube merely pierces the cork, and does not extend to any length inside, and outside it ends immediately in a jet, which can be curved round. The flask is filled with water, fitted with the two tubes, and then, with the finger on the shorter tube, is inverted, plunging the end of the longer tube in a vessel of water. The instrument may now be fixed in this position, as an intermittent jet of water begins to flow at once, continuing until the flask is empty. The column of water in the longer tube will be seen to be alternately rising and falling, from which phenomena an explanation has been given of the cause of the intermittent flow.

A POWERFUL THERMO-ELECTRIC BATTERY.—At a meeting of the Royal Institution, held some time ago, Mr. Ladd exhibited in the library a powerful thermo-electric battery, made in the manner invented by Marcus, of Vienna. Although the instrument consisted of only ten pairs, and the means of heating it by a row of gas jets had been hastily devised, yet, on making and breaking the circuit, a spark was readily obtained. The current from this thermo-electric battery was sent round an electro-magnet, and lifted a very considerable weight.

EXPLOSION OF STEAM BOILERS.

A correspondent, in furnishing us with drawings illustrative of his panacea for prevention, states his reasons as follows:—

The principal causes of boiler explosions are: defective building, furrowing, and a few from miscellaneous causes. Boilers made with lapjoints are inferior in strength, as those joints have a tendency to weaken, one plate acting as a lever to tear asunder the other, the lower edges of the plates on the one side of the boiler and the upper on the other acting as fulcrums, in other cases the whole of the strain is thrown on the rivetting. Boilers made on this principle are never true circles, in which case the strain is unequal and is thrown on the joints, which have already been strained in bending. I believe furrows to originate from chemical agents acting on the edges of the plates, which combine with the bending of the plate and the sudden strains thrown on the boiler in forming furrows. In bending the plates the fibres of the inner edges become compressed, and in rivetting and caulking the concussion of the blows shakes and loosens the compressed fibres. When steam of any high pressure is in the boiler it throws a heavy tensile strain on the com-

these difficulties. The boiler must be made of any number of equal plates, two feet broad, and one-fourth of the circumference in length to make it the given size; these plates are arranged in such a manner that there will be but two longitudinal seams under water, as seen in Fig. 2, and are rivetted to flange-plates, the arrangement of which will be hereafter described, encircled; over these (Fig. 1) is a shrunk steel strap held in its position by a number of bolts. The arrangement of the flange plates will be seen in fig 5. A, A, are the plates encircling the boiler; B, B, the longitudinal plates, the seams being shown in the dotted lines. The plates B, B, are tongued at their ends to enable them to receive the wedges cut on the plates A, A; over these the strap, D, D, is shrunk, and the plate C, which is forged on the strap, is fastened by bolts of the same size as the rivets, (fig 3).

Fig 1 is a longitudinal elevation; fig 2 is a longitudinal section; fig 3 is a plan of the strap and flange plates; fig 4 is a section of the same on the line A, B, and fig 5 is a plan of the flange plates with the strap removed. The drawings 1 and 2 are on the scale of 1 inch to the foot, and the drawings 3, 4, and 5, are made on the scale of 12-8ths to the foot. The same letters represent the same parts in

fore equal. Further, only two long and regular longitudinal seams are exposed, which present no surface for the lodgment of chemicals. In most boilers of modern make, if one side of a plate becomes furrowed and gives way, an explosion is inevitable, but according to my plan it would not be so, for the boiler cannot explode unless the flange plates give way; this will be easily understood by reference to figs 1, 3, 4, from whence it will be seen that a plate may be completely furrowed at all its edges or cracked through its centre, but that it cannot give way without the flange plates and strap giving way likewise, or the plate completely bulging out, which is next to an impossibility. The strap and flange plates being subject only to external injury, they are not likely to be much damaged, and the joints will always leak when serious damage occurs, thereby giving due warning. The flues of the boilers must be made on the same principle, reversed.

ADRIAN NEISON.

EMERY AND ITS PREPARATION.

Several correspondents having solicited information on this subject, we give them what we have to hand. In the ordinary preparation of emery the

EXPLOSION OF STEAM BOILERS.

pressed fibres of the plate, which are released and again compressed as the boiler is worked. This continued action greatly assists the furrowing by forming cracks. Having been in use some time chemical agents, derived from the feed water, are lodged on the edges of the plates, at the already weakened joints: these agents gradually eat into the cracks, destroying the fibre and thereby throwing a greater strain on the remainder. These two actions, it will be seen, "play into one another," as I may express it, and thence follows the rapid production of furrows.

To illustrate this I will take the case of the boiler that exploded at Overton Station on the 30th of May, 1864, an account of which will be found in No. 8 of THE ENGLISH MECHANIC in the article entitled "Wear and Tear of Boilers." It will be seen from the illustrations that the plate was furrowed principally on the top of the inside lap, and that "The boiler exploded just before leaving the station," when there was necessarily a greater strain on the plate from the steam being shut off. I attribute two-fifths of the damage to the chemical agents, for in boilers that have their plates cut at angles the plates have been found to last much longer, and to be nearly free from furrowing. It is obvious, then, that lap joints should not be used.

I here propose a form of boiler that would obviate

all the figures. The advantages of this kind of boiler are: 1. there are no weakened joints, &c., from the bending of the plates. 2. The boiler being a true circle, the strain is equal and thrown on the flange plates, as will be hereafter described. 3. There are but two longitudinal seams under water, and therefore liable to chemical action. 4. The edges of the plates not being exposed, there is no space for the chemicals to rest upon. 5. If one side of a plate was furrowed, that plate could not give way, by reason of the flange plate and strap.

When the boilers expand from heat and pressure, a heavy tensile strain is thrown on the flange plates encircling the boiler, which tends to draw the wedges cut on their ends out of their sockets, thereby compressing the longitudinal plates as though they were strong springs. This strain is opposed, and thereby prevented from going beyond limits by the elasticity of the steel straps encircling the boilers; and is therefore divided equally on the steel strap, flange plates, and rivetting. Some boilers have their circumferences formed of a series of plates arranged in such a manner, that the greater number of their seams form irregular and disjointed lines beneath the surface of the water, which expose a large surface for the lodgment of deleterious chemicals. I therefore consider my arrangement better, for it is a true circle, and the strain is there-

lumps of emery stone are broken up as if for macadamising. These broken lumps are then crushed under "stampers"—they being considered to leave the particles angular, which the "runners" do not. The coarse powder is then sifted through sieves of wire cloth, and the following are the numbers of wires usually contained in the sieves, and the kinds respectively produced by them:—16, corn emery; 24, coarse grinding do.; 36, grinding do.; 46, fine grinding do.; 53, super-grinding do.; 60, coarse flour do.; 70, flour do.; 80, fine flour do.; 90, superfine flour do. No. 16 gives emery about the size of mustard seed. The sieves have sometimes 120 wires to the inch; the very fine sizes are more commonly sifted through lawn sieves; but the finest obtained is that which floats in the atmosphere, and is collected on shelves, &c., whence it is often gathered. Manufacturers rarely wash the emery, which is mostly done by the glass workers, and such as require a greater degree of precision than can be had by sifting.

In washing emery by hand, washing-over is a valuable application of the law of gravity. A portion of emery powder of uncertain size is thoroughly well mixed in a large quantity of water—as in a wash-hand basin, and in 10 seconds the liquid is poured off from the sediment which in that time has fallen. The bulk is again stirred and poured off at 10

seconds, and this second sediment is added to the first—the process being repeated until no further sediment is deposited in 10 seconds. A fresh deposit is similarly collected from the residue after, say, 20 seconds, until the whole quantity of emery is divided into grains of so many sizes as may be required. The process requires a ready and steady hand. The following relates to twelve degrees of fineness in emery for the construction of machinery. No. 1, corn emery of commerce, prepared by sifting; No. 2, grinding, do.; No. 3, fine grinding, do.; No. 4, superfine grinding, do.; No. 5, deposited at the end of 2 seconds; No. 6, 5 seconds; No. 7, 10 seconds; No. 8, 20 seconds; No. 9, 1 minute; No. 10, 3 minutes; No. 11, 15 minutes; No. 12, 1 hour. Sizes 5 to 12 should be kept in glass bottles, to keep foreign substances therefrom.

For emery for optical purposes, Mr. Ross mixed 4lbs. of the flour emery of commerce with 1 oz. of powdered gum arabic, which was placed in 2 gallons of clean water. The deposit was collected, as described, at the end of 10 seconds, 30 seconds, 2, 10, 20, and 60 minutes; and that not deposited at one hour's subsidence was rejected as useless for lens grinding. The gum arabic was recommended by Dr. Green for preparing red oxide of iron, for polishing specula.

In washing emery in the large way, the following method is adopted:—Twelve or more cylinders of sheet copper, 2 feet in height, and varying from 3, 5, 8, to 30 or 40 inches diameter, are placed exactly level, and communicating at their edges to each other by small channels, the largest vessel having a waste pipe at top. At the beginning of the operation, these cylinders are filled to the brim with clean water; the pulverized emery is then churned up with abundance of water in another vessel and run into the smallest (3 inch) cylinder, through a tube opposite to the gutter leading to the second cylinder. The water, in its passage across the 3 inch cylinder, deposits in that vessel such of the coarse emery as will not bear suspension for that limited time; the particles next in fineness are deposited in the second (5 inch) cylinder during the somewhat longer time the mixed stream takes in passing the brim of that vessel, and so on. Eventually, according to Holtzapffel, the water forms a languid eddy in the largest cylinder, and deposits the fine particles, till then remaining in suspension; and, lastly, the water escapes by the waste pipe very nearly free from emery.

The paper is prepared like glass-paper, and of about six degrees of coarseness. The powders sifted through the sieves with 30 and 90 meshes to the inch being, in general, the coarsest and finest sizes employed. The cloth only differs from the paper in the employment of thin cloth instead of paper, as the material on which the emery is fixed by means of glue.

Emery paper is an article in which fine emery and glass are mixed with the paper pulp, and made into sheets as in ordinary paper. The emery and glass form about 60 per cent of the weight of the paper, which resembles drawing paper except that it has a delicate fawn colour. This paper is to be pasted or glued on a piece of wood, and, when rubbed with a little oil, to be used as a razor strop.

Emery cake consists of emery mixed with a little suet chopped small, rendered down, and mixed with a very little bees' wax, so as to constitute a solid lump, with which to dress the edge of buff and glaze wheels. The ingredients should be thoroughly incorporated by stirring the mixture whilst fluid; after which it is frequently poured into water, and thoroughly kneaded with the hand, and rolled into lumps before cooling. The emery cake is sometimes applied to the wheel while revolving; the more usual course is to stop the wheel, rub in the emery by hand—it is afterwards smoothed down by the thumb.

Emery sticks—more economical than paper wrapped round a file—are rods from 8 to 12 inches long, planed up square, or with one side rounded like the half-round file. Nails are driven into each end of the stick as tempering handles; it is then rubbed over with thin glue, and dabbed in all parts in a heap of emery powder, and knocked at one end to shake off the excess. Two coats of glue and emery are generally given.

(To be continued.)

In the year 1325 a vessel is recorded to have brought corn from France to Newcastle and to have returned laden with coal.

In 1740, the quantity of pig iron produced in Great Britain was 17,350 tons; in 1840, 1,248,781 tons; in 1863, 4,510,040 tons.

CHEMISTRY.

PREPARATION OF OXYGEN.—Mr. R. W. Artlett, writing to the *British Journal of Photography*, says:—“Having experimented on the valuable process for obtaining oxygen by the action of peroxide of cobalt on solution of hypochlorite of lime, with the view, among other things, of ascertaining what other substances might be possessed of the curious powers of the peroxide of cobalt. I have found that moist peroxide of iron or oxide of copper will answer the purpose. These substances, in the repeated trials I have made, have caused the evolution of a volume of oxygen equal to that obtained by means of the oxide of cobalt, and, like it, they lose none of their efficiency by use. The only difference I have observed is that, perhaps, the oxide of iron requires rather the highest heat to cause an equally rapid disengagement of gas. The oxide of copper answers perfectly, and if the oxide be not at hand, a few drops of nitrate of copper may be added to the hypochlorite of lime solution, and the gas will be given off abundantly immediately on the application of heat. I have also tried peroxide of manganese, but have not yet sufficiently investigated its action. I may, however, state that it does not accomplish the end in view so well as the other substances. The quantity of oxygen liberated is smaller, and permanganic acid is formed.”

DR. HOFMANN'S "INTRODUCTION TO CHEMISTRY."—The new "Introduction to Chemistry, Experimental and Theoretic," which was announced last spring as in preparation by Dr. Hofmann will, we are informed, be issued in a few days. We hear that Dr. Hofmann has again availed himself of the collaboration of Mr. F. O. Ward, and in this work we may look for a scientific pendant to the admirable treatise on Applied Chemistry published by the same author as the "Report on Class II., Section A., of the International Exhibition." The lectures Dr. Hofmann delivered last spring at the Royal Institution constitute the framework of the book, which, in its expanded form, will present a full exposition of the new system of notation, and the modern doctrines of atomic and molecular construction. The subject is confessedly one full of obscurity, and to many the new doctrines are quite a sealed book. It is, therefore, a matter of congratulation that a profound chemist like Dr. Hofmann, and a luminous writer like Mr. F. O. Ward, have been engaged conjointly in the elucidation of the difficulties. We look forward to the publication of this treatise with great interest. By the kind permission of Dr. Hofmann, we shall shortly be enabled to give our readers a chapter or two of the contents, illustrated with the original woodcuts.

OUR WEIGHTS AND MEASURES.*

The committee appointed at the meeting of the British Association in 1863, to consider the best means of providing for a uniformity of weights and measures, with reference to the interests of science, has finished and printed its report, which was read at Birmingham.

In this report the committee observe, that they "have learnt that the metric system is already in use in many great establishments. Those especially who supply machinery to the continent of Europe are under the necessity of using the metric measurement in fulfilling their orders, and it does not appear that the workmen in such establishments have any difficulty in understanding the system, and in using it with as much readiness as the imperial scale." They also remark,—"Nowhere could we see more clearly the need of altering the present practice than in the practical routine work in railway management. With the enormous traffic of our railway companies, the inconvenience of the present subdivision of weights produces a decided appreciable loss to the income of the shareholders."

It is calculated that on an average the clerks commit one error in every 500 items; and the consequence is that the London and North Western Company are under the necessity of nearly doubling the number of clerks. For every 100 clerks employed in weighing or measuring, and taxing packages, nearly another 100 are wanted to correct the errors committed. But with a decimal and metric system this liability to error is immensely reduced, and therefore a practical economic benefit would certainly arise from the adoption of that system in railway traffic. As a practical mode for diffusing information on the metric system, it has been suggested to fix the metric standards in one or more frequented places in the leading commercial cities of the empire." In conclusion the committee recommend "the reapp-

pointment of this committee, with power to use such measures as they may deem expedient for promoting the extensive use of the metric system in scientific and official documents in the Custom-house and Post-office, as well as the teaching of the system in schools and colleges; with instructions also as regards the coinage, to represent to Her Majesty's Government the expediency of the early adoption of such a system of decimalisation as will the more effectively facilitate the social and commercial transactions of the country, and at the same time advance the great purpose of international exchanges, and especially to urge upon Her Majesty's Government the great benefit that would arise from the early assembling of an international monetary convention, as recommended at the last meeting of the International Statistic Congress, held in Berlin."

Mr. F. P. Fellows read a paper "On the practical advantages of the metric system of weights and measures." The paper commenced by showing that the saving of figures to be written, and therefore of time, by the metric system of weights and measures over that of England is as six to one, and this merely in consequence of the decimalization of each unit of the metric system. Calculations were given to prove this. It next showed the great advantage this system offers, in consequence of its weight, measures of capacity, square, and cubic measure, being directly and decimally related to the measures of length and consequently to each other, giving practical examples to illustrate this. It then pointed out that the universally received English equivalent of the metre is incorrect, and gave the correct equivalent, and indicated how this error must prevent the adoption of the system in England for scientific investigations requiring great accuracy. Mr. Fellows next drew attention to certain errors in the Government schedule or table of metric weights and measures attached to the Metric Weights and Measures Act, showing how those errors must prevent its safe use for trading purposes. He concluded by recommending the correction of the equivalent and the errors in the Government schedule before any further legal steps are taken to advance the system.

In connection with this subject, Professor Rogers said he did not desire that the working classes should be compelled by law to adopt it, but that it should be taught in all the National Schools, and that instruction in it should be included in the Oxford and Cambridge Middle Class School Examinations.

Lord Stanley, who presided over the section, wound up with a lot of second-hand matter, which amounted to this, that the advocates of the metrical method must not be in a hurry. They had a long job before them. They must first get people to consider the subject, and the more people did that they would see the necessity of some change in our present weights and measures, and that, if there must be a change, it could only be made in that direction. That reform would take time, but it would succeed in the end.

A PLAIN glass mirror reflects 5352 of 1,000 rays—the quicksilver reflects two-thirds.

SWEET tan is sometimes substituted, with excellent results, for charcoal in blasting powder.

A new rudder on Lumley's patent is being constructed for the screw troopship "Orontes," at Portsmouth dockyard, and will be fitted to that vessel on her return to England from her present China voyage. The Lumley rudder, which is fitted to Her Majesty's ships "Columbine," "Scotia," and six other vessels in the navy, is one of the most simple yet efficient, forms of steering that can be applied to single screw ships, yet, strange to say, none of our large ironclads have yet been fitted with it.

We understand that there never was, more than now, a larger consumption of tin plates. Not only are most of the tin-plate workers who produce wares in common use very busy, but, on every hand, there is an extension of the use of this material for packing purposes. The large quantity of goods, of an edible kind in particular, which are now sent from the manufactories in canisters and boxes made of tin plates is something astonishing.

GLUE FOR CABINET-MAKING.—Common glue, as used by cabinet-makers, is not always sufficiently strong to resist the strain to which the pieces joined together with it may happen to be exposed; sometimes even it is required to make metal, glass, or stone adhere strongly to the wood, in which case a mixture of glue and ashes will be found greatly preferable to glue in its ordinary state. The latter should first be reduced to the proper consistency required for wood, and a sufficient quantity of ashes added to give it the tenacity of a varnish. It must be applied hot.

* Proceeding in Section for Economic Science and Statistics, British Association.

RECENT AMERICAN PATENTS.

DEVICE FOR REELING CORD.—This invention relates more particularly to an arrangement of mechanical devices to be applied to the handle portion of a fishing pole, either upon its inside or outside, for reeling the line, and consists principally in imparting to the spool or reel upon which the line is wound a reciprocating rectilinear movement, while at the same time it is revolved, whereby the line can be evenly wound, and with dispatch and facility. The operating devices for the spool are also so arranged that, when desired to unreel the line, they can be thrown out of gear, as it were, with the spool, leaving it independent of them, and free to revolve on its axis or shaft. The arrangement of this reeling device is simple and ingenious in many respects, and its operation quite free and accurate; and for the purpose for which it is especially intended it possesses many important advantages over the ordinary reeling devices now in common use for fishing poles. William M. Stuart, of New Jersey, is the inventor.

FIRE ALARM.—This invention relates to an apparatus the operation of which is based upon the expansion and contraction of a spring composed of two different metals or other materials. The outer end of this spring is connected to an elbow lever, which is secured to a vertical arbor bearing an index, which traverses over an adjustable scale, and when the temperature rises beyond the desired point, said index, by coming in contact with the end of a lever, releases a tilting weight, and, by the action of this tilting weight, another similar weight is released, and thereby the escapement of a clock movement is freed, and said movement being driven by a weight or spring, causes a hammer to strike repeated and rapid blows on a bell, so that the attention of persons in the room, building, or other structure is called to the fact that the temperature has reached its maximum. The scale and spring are situated on a common bed-plate, and by adjusting this bed-plate the point, when the alarm is released, can be adjusted at pleasure. Charles Dion, Montreal, Canada, is the inventor.

GREASE CUP.—This invention consists in the application of two valves, connected together by a jointed stem, which can be easily lengthened or shortened, in combination with two seats, one above and the other below the bulb or reservoir of the grease cup, in such a manner that, by turning the handle attached to the valve stem in one direction, the lower valve is closed and the upper valve opened ready to admit the lubricating material from the receiving cup into the bulb, and by turning said handle in the opposite direction, the upper valve is closed and the lower valve opened, and the interior of the bulb brought in communication with the steam cylinder or other device to be oiled. In order to allow the steam and air contained in the bulb to escape, when it is desired to introduce the lubricating material into the same, it is provided with a spring valve which will open by a slight pressure of the hand, and when released, close by the action of a spring combined with that of the steam in the interior of the bulb. Gebhard Hagenmeyer, of Big River, Cal., is the inventor.

JAR FOR WELL-BORING TOOLS.—In boring deep wells, such for instance as oil wells, a device is connected with the drill or drill rod to admit of the drill, in case of the latter becoming fast, being subjected to a series of blows or concussions in order to loosen it. This device, commonly termed a "jar," is indispensable in boring deep wells, owing to the great difficulty which would be otherwise experienced in withdrawing or loosening the auger. The ordinary jar in use is attended with some disadvantages. It is liable to get fast itself, and is subjected to considerable wear in consequence of being in contact with the grit in the wall of the well. It is also liable to break or give way when worn, and the withdrawing it from the well is attended with considerable difficulty; these advantages, it is believed, are fully obviated by this invention. Miles Joy, of West Greenville, Pa., is the inventor.

It might be supposed there was now little danger of the explosion of shells fired at the siege of Sebastopol and which had remained exposed ever since to the rains and snows of the Crimea; but the *Odessa Courier* says that accidents continue to occur from the bursting of such shells, and states a case of recent occurrence. Some boys found a shell in the neighbourhood of Bastion No. 4, and began to roll it in the direction of the town. It struck against a stone and instantly burst. Luckily no one was hurt, although one of the boys was so near the shell that his clothes were set on fire by the explosion.

NEW COAL-CUTTING MACHINERY.

Heretofore, when getting coal or other minerals by means of picks or cutters actuated by machinery, the cutters have been usually carried by trucks running on rails laid on the floor of the mine, along the front of the face of coal upon which the cutters are to be made to operate, and difficulty has been experienced in laying the rails securely, to prevent their shifting when the machine is at work. To improve upon this, Mr. G. Donisthorpe has patented an invention, according to which he employs posts and pillars, wedged or held between the floor or roof of the mine, to hold the rails in position, and prevent them shifting sideways away from the face of the work. The posts may be constructed in various ways to accomplish this object, but he prefers to make them capable of being elongated by means of a screw, and when using them holes are bored in the floor and roof to receive their upper and lower ends. In fixing such posts in holes previously bored to receive them, the lower end of the post would first be stepped into the hole in the floor, and the post then elongated, to cause its upper end to enter the hole in the roof; collars are placed on the posts near their upper and lower ends, and the screw is turned until these collars bear firmly against the floor and roof respectively; by these means the posts will be firmly held; the rails are by preference carried by transverse iron sleepers, having the chairs to receive the rails formed in one piece with them, and a post, such as above described, is placed opposite each sleeper at the end that is furthest from the work. The end of the sleeper is connected to the post at the requisite height from the floor, to bring the rails to the desired level, the post and sleeper being for this purpose suitably constructed to allow of the sleeper being connected to the post at any desired height. The end of the sleeper nearest to the work is packed or blocked up from the floor of the mine, to bring the inner rail to the correct level.

ORDNANCE AND TARGETS.

The Admiralty having erected a new target, representing a portion of the side of the *Hercules*, experiments were made at Shoeburyness which proved that a thickness of armour casing had been attained which afforded perfect security against even the largest guns recently constructed. The target has a facing of 9-inch armour-plates, and contains altogether 11 inches thickness of iron. Against this, three 12-ton shunt guns were fired, at a distance of only 200 yards, with charges varying from 45lb. to 60lb. of powder. One steel shot, of 300lb. weight, 10½ inches in diameter, fired with 60lb. of powder, at a velocity of 1,450 feet per second, barely broke through the armour, without injuring the backing. Sir William Armstrong has expressed his conviction, in the *Times*, that the 600-pounder gun will be unable to penetrate this target, and that it will, in fact require a gun carrying 120lb. of powder and steel shot to pierce this massive shield. Mr. W. C. Unwin has pointed out, in a letter to the *Engineer*, that for similar guns, with shot of similar form, and charges in a constant ratio to the weight of the shot, the velocity is nearly constant. Then, assuming the resistance of the plates to be as the squares of their thicknesses, it follows that when the diameter of the shot increases, as well as the thickness of the armour, the maximum thickness perforated will (by theory) vary as the cube root of the weight of the shot, or, in other words, as the calibre of the gun; and the weight of the shot necessary to penetrate different thicknesses of armour will be as the cubes of those thicknesses. The ratio deduced from the Shoeburyness experiments is somewhat less than this, being as the two-fifths power and the five-second power respectively. Practical formulae deduced from experiments are given, which agree with Sir William Armstrong's conclusion, and prove that a gun which can effectively burn a charge of at least 100lb. of powder will be required to effectually penetrate the side of the *Hercules*.

FORCE EXERTED BY VEGETABLE GROWTH.—Some idea may be formed of the force exerted by vegetable growth from the fact stated in reference to an enormous specimen, *Agaricus cartilagineus* (mushroom), which was sent to the British Museum. It was found growing below the pavement in the Goswell-road, and its mycelium, or filamentous body, from which this fungus growth is developed, which, in this case, was developed into an enormous spongy mass, had, in pushing up its many-headed pileus, raised a stone weighing two hundred weight, and measuring four feet square.

RANDOM NOTES.

M. JEANNEL has discovered a new way of easily ascertaining whether there exists any lead in the tin used for tinning culinary vessels in hospitals. His method consists in this:—Take about five decigrams of scrapings of the metal to be tested, and boil it in an excess of nitric acid diluted with one-third of its weight of water. When the solution is complete, filter and then put in a crystal of iodide of potassium. If the liquid contains but a ten-thousandth part of lead, a yellow precipitate will be formed, which will not disappear by the addition of an excess of ammonia.

EXPERIMENTS on the N. Y. Central railroad with peat show that 2,800lbs of peat will run an engine about 175 miles.

COLOURS ON INDIA-RUBBER.—The *Druggist's Circular* says:—"The surface of the object is covered over with a thick solution of caoutchouc in turpentine rubbed up with white zinc, and when this is thoroughly dried, the colour which it is desired to apply is put on mixed with turpentine.

ALUM BAY SAND.—We are pleased to observe that the Alum Bay pits, from which the famous white sand for making glass is obtained, are once more in full work. A very large trade was formerly carried on with it by Messrs. Squire, who held the agency, but owing to various circumstances the demand fell off, and has been of late years almost nominal. An enterprising firm have now, however, taken a lease in it, and by the aid of tramroads laid down in the pits, and other modern improvements, a very large quantity can now be shipped in a short space of time. —*Hampshire Advertiser*.

ONE grain of gold will cover 52 square inches, or be 1,500 times thinner than writing paper.

SOLID carbonic acid sinks the spirit thermometer to 162 deg. Fah. below zero in two minutes.

THE German Ocean is 3 deg. colder in winter and 5 deg. warmer in summer than the Atlantic.

BOTH eyes make an object appear one-thirteenth brighter than when looked at with one eye.

THE ascending power of a balloon with hydrogen gas to one filled with coal gas is as 15 to 11 nearly.

GOLD leaf can be reduced to the 300-thousandth part of an inch; silver leaf to the 170-thousandth.

GUNPOWDER was first used in England for blasting in 1665, in Germany it was used as early as 1613.

THE proportion of sulphur in the human hair is as follows:—Brown, 4.98; black, 4.85; red, 5.02; grey, 4.03. It is stated by some that the colouration of hair is due to the different proportions of sulphur it contains, by others to the presence of iron.

EULER determined the direct light of the sun to be equal to 6,500 candles, a foot distant; that of the moon to one candle 7½ ft.; that of Jupiter, 1 at 1,320 ft.; and Venus, 1 at 42 ft.

THE middle of the centre arch of Southwark Bridge rises one inch in the heat of summer, and the effects of a gleam of sunshine on the Britannia Bridge is immediately perceptible.

THE manufacture of clasp knives was introduced into Sheffield in 1650, such knives having been previously known as jockeys, from Jacques de Liege, a celebrated foreign cutler.

It is not generally known that lead is frequently attacked by a species of insects, the larvae of which excavate circular passages in it. The insects do not eat the lead, but simply bore it out.

Or 10,000 rays of light only 8,123 reach the earth when the sun is vertical. 8,000 at 70 deg. high 7,624 at 50 deg., 7,237 at 40 deg., 5,474 at 20 deg. 3,149 at 10 deg., 1,201 at 5 deg., and 47 at 1 deg.

INDUSTRY AT WEDNESBURY.

Wednesbury is the principal seat of the manufacture of railway plant. Axles, wheels, and other descriptions of rolling stock, are made here in enormous quantities, one firm alone employing over 3,000 workpeople, and paying some £5,000 per fortnight in the shape of wages. Tubing is also an important department of manufacture here, being made most extensively for gas and water companies, and also for marine purposes. Wrought heavy ironwork, such as girders, boilers, tanks, and kindred articles, are produced in great quantities, as also is iron fencing. We have heard of a single order for the latter amounting to 600 miles for a railway abroad. India is becoming a vast and important market for these articles, and, great as the production now is, there is every promise of a still greater development of industry here. The miscellaneous branches of manufacture include foundry ware, wagon arms, engine fittings, and gun locks. Formerly pottery was one of the productions of Wednesbury, but that industry has altogether died out. About 10,000 persons are employed in the various manufacturing trades of the parish.

THE ANGLO-FRENCH EXHIBITION.

The calls upon our space have been, and are such as to prevent our entering into detail concerning the great mass of objects on view; but we still have room to notice anything turning up of a character deserving of extra attention. We have now to notice a fine piece of wrought iron work by an English mechanic, named Lethwen, of Cheltenham. It is a bracket composed partly from one of the 16th century, and partly of the worker's design, and each piece is *welded* together, there being no brazing or soldering of any kind, nor is it much filed. He also exhibits another object—ivy leaves and berries. These latter are all forged, and their separate stems welded on to the stalks. The wonder is, how it could be done without burning them off. Our readers will do well to pay a visit to the Exhibition; with the thousands of other objects on view in the building the fare is low.

PATENT LIST.

(From the Commissioners of Patents' Journal.)

LIST OF SPECIFICATIONS, &c. PUBLISHED DURING THE WEEK ENDING 30TH SEPTEMBER, 1865.

2741. Breech-loading fire-arms, J. Bulder, jun.—8d.
 2742. Embossing or indenting paper, J. R. Crompton—8d.
 2743. Weaving figured fabric, D. Ellis and M. Hulas—1s. 4d.
 2744. Sprigging liquids over wool, cloth, &c., M. J. Roberts—10d.
 2745. Cotton gins, H. V. Scattergood—10d.
 2746. Securing rivets and sheathing, G. Haselton, 8d.
 2747. Railway bars, girders, beams, joists, and angle irons, J. D. Young—4d.
 2748. Non-conducting composition for preventing radiation A. Etourneau and L. Beauchamps—4d.
 2749. Distilling apparatus, L. H. Bickes—4d.
 2750. Printing machines, G. Duncan—4d.
 2751. Rotary engine pump or blast, M. Thrift—1s.
 2752. Manufacture of oakum, D. Cullen—4d.
 2753. Buffers, G. Simpson—8d.
 2754. Hydraulic press, A. Steven—4d.
 2755. Cleansing grain, W. E. Gedge—4d.
 2756. Packing, R. A. Brooman—6d.
 2757. Filters, J. Black—4d.
 2758. Blowing cupolas, blast-furnaces, &c., J. M. Stanley and J. Stanley—4d.
 2759. Breech-loading fire-arms and cartridges, W. R. Newton and R. C. Shepard—1s. 6d.
 2760. Hooped skirt, A. V. Newton—8d.
 2761. Portable centrifugal pumps, C. T. Burgess—10d.
 2762. Night lights, A. Field—6d.
 2763. Guns and fire-arms, G. P. Harding, and T. Lynall—6d.
 2764. Locomotive engines, &c., W. B. Adams—1s.
 2765. Rack for holding blind cord, R. M. Adams—1s.
 2766. Apparatus for drawing off liquids, R. Kinner—8d.
 2767. Signalling on railways, J. Henshaw—4d.
 2768. Grinding corn, J. Hurd and H. Tonge—4d.
 2769. Stamping machine, L. C. Meville—1s.
 2770. Obtaining power from liquids, C. Garton—8d.
 2771. Raising screw propeller, W. K. Hall—6d.
 2772. Rolling metals, A. Becham and H. Wedekind—1s. 2d.
 2773. Treating yarns or threads and textile fabrics, J. H. Johnson—8d.
 2774. Boots and shoes, J. Okey—4d.
 2775. Chimney pots, J. Bell—4d.
 2776. Extracting silver from lead, A. Moreau—4d.
 2777. Breech-loading fire-arms and cartridges, S. Rydbeck—10d.
 2778. Straw hats, J. D. Welch and A. P. Welch—4d.
 2779. Motive power, G. B. Galloway—4d.
 2780. Bill file, S. Dixon—1s. 4d.
 2781. Construction of ships and vessels, J. Robinson—4d.
 2782. Traps for drains, S. C. Reed—4d.
 2783. Conveying sea water, J. Rae—4d.
 2784. Gun barrels and ordnance, J. Thompson—4d.
 2785. Colouring matters, J. Dale, H. Caro, and C. A. Martins—4d.
 2786. Filter or press, W. E. Newton—10d.
 2787. Cap or stopper for bottles, F. Lane—4d.
 2788. Collecting and treating night soil, J. A. Manning—4d.
 2789. Injection for steam boilers, J. Robinson and J. Graham—2s. 6d.
 2790. Hats, caps, and bonnets, R. B. Cooley—4d.
 2791. Lamp globe or shade, M. A. F. Mannons—4d.
 2792. Steering apparatus, M. W. Butler—6d.
 2793. Shaping and sharpening saws, E. J. W. Parnock—1s. 4d.
 2794. Preserving fresh meat, &c., J. McCall and B. G. Sloper—4d.
 2795. Manufacture of pottery, &c., T. L. Boots and E. Boots—4d.
 2796. Steam engines, &c., J. Simes—4d.
 2797. Railways, H. Brockwell—1s. 8d.
 2798. Paper, L. Cooke—4d.
 2799. Torpedo rams, G. A. Henry—4d.
 2800. Copying drawings, &c., W. Willis—4d.
 2801. Cement, W. L. Lees—4d.
 2802. Mills for crushing sugar, G. Dixon—4d.
 2803. Generating motive power, W. Clark—1s. 10d.
 2804. Looms, W. Clark—10d.
 2805. Cleaning forks and spoons, J. Cockshott—4d.
 2806. Densitizing, G. Smith—10d.
 2807. Moulds, J. Kinniburgh—10d.
 2808. Sanitary toilet apparatus, W. E. Gedge—4d.
 2809. Softening or deadening sound, F. Fearon—6d.
 2810. Moulds, W. E. Gedge—4d.
 2811. Developing heat, W. C. Thurgar and R. A. Ward—8d.
 2812. Cages, C. Mohr and S. E. Smith—6d.
 2813. Fog signals, E. Richardson—4d.
 2814. Working ship pumps, C. W. Hecforth—4d.
 2815. Washing machines, J. Thorne—8d.
 2816. Compressing gunpowder for blasting, &c., H. Sutherland and E. Sutherland—8d.
 2817. Sewing machines, J. Keats and W. S. Clark—1s.
 2818. Knapsack supporter, G. Davies—4d.
 2819. Carriage heads, C. Martin—1s.
 2820. Closing envelopes and affixing stamps, W. Fisher—4d.
 2821. Tonic malt liquors, F. A. Paps—4d.
 2822. Sewing machines, J. McCloskey—4d.
 2823. Whips, umbrellas, &c., C. S. Cowman—4d.
 2824. Feeding millstones, E. F. Woods and J. S. Cocke—4d.
 2825. Preparing or dyeing wool and hair, H. W. Ripley—4d.
 2826. Signalling in railway trains, C. Cotton and W. Nunn—4d.
 2827. Regulating the supply of gas, C. Kaplan—4d.

THE METAL MARKETS.

RAILS continue in great demand, and higher rates are not improbable; the makers are very full of orders, and each mail from America brings fresh business.

COPPER.—More business doing; BUTTS £90, tough Cakes, £85. Tin in better request; Banca, £92, Fine Straits, £88 per ton. Tin PLATES on the advance; Coke, 23s. 6d., and Charcoal, 29s. per box.

LEAD, more business. English £10, and soft Spanish £18 15s. per ton. SPLITTER is quoted at £21 5s. on the spot, and £21 10s. to arrive.

FOR SALE, A Self-acting, Turning, and Screw-cutting Lathe. 10 inch centres, with bed 16 feet long; also a second-hand planing machine, to plane 4 feet by 2 feet. Apply to W. Blackett, Hope Iron Works, 106, Southwark-bridge-road, London.

THE IMPROVED LEATHER DRIVING STRAPS FOR MACHINERY are stronger for a given weight, more effective, more durable, and cost considerably less than any other kind of Driving Belt. Special Straps for Portable Engines. Price Lists free.

Turner's Patent Strap and Hose Company. Manufactory, Armit Works, Greenfield, Manchester. Warehouse, 81, Mark-lane, London, E.C. Mr. H. FERRABEE, Agent.

JOSEPH STANLEY,

(Late Foreman at David Hart's.)

ENGINEER AND BUILDERS' PATTERN MAKER.

33, FIELDGATE-STREET, WHITECHAPEL-ROAD, E. Patterns designed and arranged from instruction according to requirement.

MODELS AND PATTERNS

for INVENTORS, MACHINISTS, AND ENGINEERS,

Made in all their branches by G. TAYLOR.

140, St. John-street, West Smithfield.

NATIONAL BOILER INSURANCE COMPANY (LIMITED),

27, LEADENHALL-STREET, LONDON.

JOHN SMITH & Co., ENGINEERS AND BOILER MAKERS,

Sole London Agents.

All Boilers supplied by this firm insured the First Twelve Months Free of Charge.

T. R. TAYLOR.

MODELLER OF NEW INVENTIONS,

LATHE, TOOL MAKER,

AND GENERAL MACHINIST,

110, FETTER-LANE, FLEET-STREET, LONDON, E.C. Patterns made to drawing.

W. SPEECHLEY,

ENGINEER, MACHINIST, AND LATHE MAKER,

No. 118, RAILWAY ARCH, VAUXHALL-WALK, S.

JAMES LEWIS.

(Late Lewis & Son),

ENGINEER, MACHINIST, LATHE & TOOL MAKER, and Modeller of New Inventions.

41, GREAT QUEEN-STREET, LINCOLN'S INN-FIELDS.

(Late of 5, Wych-street, Strand.)

Machinery made to Drawings or Patterns, and Worked out to Scale.

W. & A. GLOVER,

ENGINEERS, MACHINISTS, LATHE, AND TOOL MAKERS,

191, OLD KENT ROAD.

SCREW CUTTING, TURNING, AND PLANING.

"THE ARTIZAN."

PATENT OFFICE & DESIGNS REGISTRY,

(Office of "The Artizan" for Scotland.)

W. R. M. THOMPSON & Co., 20, Buchanan-street, Glasgow,

Consulting Engineers and Patent Agents.

WILLIAM SMITH, Esq., C.E., Director of the Artizan Patent Office, London, Proprietor and Editor of the "Artizan," a Monthly Record of Engineering and the Industrial Arts, TRANSMIT ALL BUSINESS RELATING TO BRITISH AND FOREIGN PATENTS FOR INVENTIONS, AND THE REGISTRATION OF DEVICES, AND EXECUTE PLANS AND SPECIFICATIONS OF ALL KINDS OF MACHINERY IN THE MOST CORRECT MANNER, AT THE LOWEST POSSIBLE CHARGE. Provisional Protection, £3 5s. Ordinary Charges for Complete Patent, £42.

All general information in reference to Patents given free on personal application, or by letter, when an addressed stamped envelope is enclosed.

The "Artizan" supplied, and all business for it in Scotland may be transacted at the above Office, 20, Buchanan-street, Glasgow.

In case, folded for the pocket, or on roller, price 5s.

DR. REHRHST'S ENGINEER'S, Manufacturer's, and Miner's VADE-MECUM; giving in five languages, 300 technical terms in common use among Engineers, Manufacturers, Miners, &c. London: F. Pittman, 20, Paternoster-row, E.C.

SCREW CUTTER'S GUIDE,

Containing 115 Pages and nearly 2,000 Tables of Wheels, all different threads and pitches.

Tables for Tap making for Engineers, 1 to 6 inches, Gas Tape 1/16 to 1/2 inches, Mr. Whitworth's thread and make.

A lithograph showing a new radius gear invented by the author of this work.

May be had at James Martin, 19, Wilson-street, New Cross-road, Deptford, Kent.

Just published, 32mo., cloth, 6d.

ROAD LOCOMOTIVES, an Epitome of the New Road Locomotive Acts for the use of Owners and Drivers, with an introductory preface, by Thomas Aveling, London,

E. and F. N. Spon, 16, Bucklersbury.

NEW WORKS PUBLISHED

BY

E. & F. N. SPON,
16, BUCKLERSBURY.

Just published, 8vo. cloth, price 18s.

PRACTICAL SPECIFICATIONS OF WORKS executed in ARCHITECTURE, CIVIL and MECHANICAL ENGINEERING, and in ROAD-MAKING and SEWERING: to which are added a Series of practically useful Agreements and Reports. By JOHN BLENKARN, Civil Engineer and Architect. London: E. and F. N. Spon, 16, Bucklersbury.

Royal 8mo. roan, price 5s.

A HANDBOOK FOR ARCHITECTURAL SURVEYORS, and Others Engaged in Building. By JOHN THOMAS HURST, C.E.

CONTENTS. Formulae useful in Designing Builders' Work. Tables of the Weights of Materials used in Building. Memoranda connected with Builders' Work. Architectural Mensuration. Constants of Labour. Valuation of Property. Summary of the Practice in Dilapidations. Scale of Professional Charges, for Architects and Surveyors, with various useful Tables and Memoranda. London: E. and F. N. Spon, 16, Bucklersbury.

Just published, elephant folio, cloth, price £3 3s.

Kept also in Limp Binding at the same price (can be rolled up in a small compass without injury to the plates).

PRACTICAL ILLUSTRATIONS of LAND and MARINE ENGINES, showing in Detail the Modern Improvements in High and Low Pressure, Surface Condensation, Superheating, together with Land and Marine Boilers. By N. P. BURGH, Engineer.

London: E. and F. N. Spon, 16, Bucklersbury.

Royal 8mo. roan, 4s. 6d., post free.

RULES for DESIGNING, CONSTRUCTING, and ERECTING LAND and MARINE ENGINES and BOILERS.

By N. P. BURGH, Engineer.

London: E. and F. N. Spon, 16, Bucklersbury.

Eighth Edition, in royal 8mo. roan, price 4s. 6d., post free.

A POCKET BOOK of USEFUL FORMULAE and MEMORANDA, for Civil and Mechanical Engineers. By GUILDFORD L. MOLESWORTH, Memb. Inst. C.E.

London: E. and F. N. Spon, 16, Bucklersbury.

Just published, on a Sheet, price 1s.

DELANEY and OKE'S WAGE TABLES for ENGINEERS, SHIP-BUILDERS, CONTRACTORS, BUILDERS, &c., from a quarter of an hour, in regular progression, to nine hours and three-quarters, and from one day to ten days, at 1s. to 8s. per day.

London: E. and F. N. Spon, 16, Bucklersbury.

Just published, royal 8vo., price 7s. 6d.

THE SEWING MACHINE: Its History, Construction, and Application. Translated from the German of Dr. HERZBERG, by UPFIELD GREEN. Illustrated by Seven large folding Plates.

London: E. and F. N. Spon, 16, Bucklersbury.

600 pages, crown vo., price 10s. 6d.

PERPETUAL MOTION. Its History during Three Centuries: with ample Descriptions and Illustrations. By HENRY DIRCKS, Civil Engineer.

London: E. and F. N. Spon, 16, Bucklersbury.

Royal 8vo., cloth, illustrated with 41 Plates, price 18s.

A PRACTICAL TREATISE on the SCIENCE of LAND and ENGINEERING SURVEYING, LEVELLING, ESTIMATING QUANTITIES, &c., with a General Description of the several Instruments required for Surveying, Levelling, Plotting, &c. By M. S. MERRITT.

London: E. and F. N. Spon, 16, Bucklersbury.

Just Published, royal 4to., half-bound, illustrated by 64 Plates of Furnaces and Machinery, price £2 2s.

THE IRON MANUFACTURE of GREAT

BRITAIN, Theoretically and Practically Considered; including Descriptive Details of the Ores, Fuels, and Fluxes employed; the Preliminary Operation of Calcination; the Blast, Refining, and Puddling Furnaces, Engines and Machinery, and the various Processes in Union, &c. By WILLIAM THURAN, C.E., formerly Engineer at the Dowlais Iron Works, under the late Sir John Guest, Bart., subsequently at the Herwall and Forests Works, under Mr. Crawshaw. Third Edition revised from the Manuscript of the late Mr. Thurau. By J. Arthur Phillips, Author of "A Manual of Metallurgy," "Records of Mining," &c., and W. H. Dorman, C.E.

London: E. and F. N. Spon, 16, Bucklersbury.

Just Published, post 8vo. cloth, 3s. 6d.

MEMOIRS of the DISTINGUISHED MEN OF SCIENCE of GREAT BRITAIN, LIVING A.D. 1847-4. By W. WALKER, Jun., with an Introduction by Robert Hunt, F.R.S. Second Edition, revised and enlarged.

Containing the lives of Watt, Rennie, Telford, Mylne, Jessop, Chapman, Murdoch, the first to introduce gas into practical use; Rumford, Haidart, Boulton, Brunel, Wainwright, Benthams, Maudslays, Daltons, Cavendish, Sir Humphry Davy, Wollaston, Hatchett, Henry, Allen, Howard, Smith, the father of English geology; Crompton, inventor of the Spinning Mule; Cartwright, Tennant, Ronalds, the first to successfully pass an electric telegraph message through a long distance; Charles Earl Stanhope, Trevithick, Nasmyth, Miller, of Dalwinton, and Symington, the inventors and constructors of the first practical Steamboat; Professor Thomson, of Glasgow; Troughton, Donkin, Congreve, Herschel, Macskelney, Baily, Fodsham, Leslie, Playfair, Rutherford, Dollond, Brown, the Botanist; Gilbert and Banks, the Presidents of the Royal Society at that epoch of time; Capt. Kater, celebrated for his pendulum experiments; Dr. Thomas Young, and Jenner, the benefactor of mankind; Jas. Ivory, Dr. Priestly and Cort, the father of the iron trade.

London: E. and F. N. Spon, 16, Bucklersbury.

JOINERS' HALL BUILDINGS, 79, UPPER THAMES STREET, E.C.,
LITHOGRAPHER, PRINTER, ARTIST, AND DESIGNER,**

PLANS, DESIGNS, SPECIFICATIONS, AND EVERY DESCRIPTION OF ENGINEERING DRAWINGS EXECUTED WITH RAPIDITY AND ECONOMY.

Estimates forwarded for All kinds of Turret Clocks.

Estimates forwarded for All kinds of Turret Clocks.

GOLD FROM 8 GUINEAS. SILVER FROM 5 GUINEAS.

C. SUFFELL, MATHEMATICAL INSTRUMENT MAKER, 11, BRIDGE-STREET, WESTMINSTER, begs to call attention to his improved Levels and Theodolites, as manufactured for Her Majesty's Government. The pocket sets of instruments, from 16s. to 42s.; Telescopes, 5 miles range, from 6s. 6d.; 10 miles ditto, 8s. 6d. and 10s. 6d.; Boxwood scales, engine divided, 2s. 6d.; T squares, 1s. to 5s.; Measures and Rules of all nations. Post-office orders payable at Charing Cross branch. Lists of prices forwarded on application.

SMITH'S PATENT WIRE ROPE AND CABLE MACHINE, guaranteed to produce Four times the usual quantity of Work, of Superior Quality, at One-Third the Cost for Labour. REFERENCES TO ALL THE PRINCIPAL ROPEMAKERS IN THE KINGDOM AND ON THE CONTINENT. Every description of Machinery and Repairs at Reasonable Prices. **ARCHIBALD SMITH, 69, PRINCES-STREET, LEICESTER-SQUARE, W.**

TUCK'S PATENT STEAM PACKING.
TUCK'S PATENT ELASTIC PACKING AND METALLIC LININGS FOR STEAM-ENGINES, PUMPS, &c.
ADVANTAGES.—A more perfect vacuum is obtained. Friction reduced, great saving in oil and tallow, and the Packing is gradually and completely worn away without becoming hard, thus obviating the necessity of drawing the Old Packing.

J. H. TUCK & CO., 35, CANNON STREET, E.C.

VULCANISED INDIA RUBBER GOODS. VALVES, WASHERS, HOSE, MILL BANDS, &c.
J. H. TUCK and CO., 35, CANNON STREET, E.C.

W. LANGTON'S PATENT SELF GENERATING GAS STOVE
BOILS or Frys by Methylated Spirits generated into Gas, free from smoke or smell, and is the most useful and economical invention ever offered to the public.
Said by all Ironmongers, and at the Manufactory.
36, CHARLES-STREET, HATTON-GARDEN.

To Electricians.
GAS CARBON (not compressed) Cut in Plates or Blocks for Batteries
Price Lists, on application with stamped envelope.
F. HENDERSON, 3, Park-hill, Clapham, Surrey.

CIRCULAR SAW BENCHES FOR FOOT OR STEAM POWER.
Suitable for Cutting Brass, Ivory, Hard-woods, Picture-frame Work, &c.
All kinds of Machinery made to order.
HUMPHREY and HASLER, 69, Old-street, St. Luke's, London, E.C.

WHEEL, RACK, AND SCREW CUTTING.
SPUR, BEVEL, RATCHET, WORM AND INTERNAL WHEELS cut to any size or number of teeth; also racks of any length or pitch. Dividing plates drilled or lined. Screws cut to any size or pitch. **J. Wilkinson, Engineer, St. George's Works, 33, St. George's-road, S. London.**

"EXCELSIOR," "EXCELSIOR"
Family Sewing & Embroidering Machine

WITH ALL THE LATEST IMPROVEMENTS.

IS easy to operate, simple to learn, quiet in action, and not liable to derangement. It will TUCK, HEM, FELL, GATHER, CORD, QUILT, BRAID, and sews from two ordinary reels, requires no re-winding, and the seam, if cut at every inch, will not rip. Price from £6 6s.

WHIGHT AND MANN, 143, HOLBORN BARS, LONDON.
MANUFACTORY—GIPPING WORKS, IPSWICH.
PRICE LISTS FREE.

GEORGE CUTLER, Junr., MANUFACTURING ENGINEER, LONDON GAS-HOLDER AND BOILER WORKS, 8, WHARF, WENLOCK ROAD, CITY ROAD, N., LONDON. Contractor for Tanks, Gas-holders, Roofs, Purifiers, and all descriptions of Gas Apparatus executed on the most reasonable terms. Steam and Range Boilers of the best material and workmanship on the shortest notice. **MAKER AND PATENTEE OF THE GAS HEATED STEAM BOILER.** Slide and Bypass Valves for Gas or Water Works, Bolts, Rivets, Retort Screws and Doors kept in Stock. Gas Works supplied and erected complete with main and service laying.

**RAMSBOTTOM'S
PATENT DISPLACEMENT LUBRICATOR**

FOR LUBRICATING THE PISTONS, CYLINDERS, AND VALVE FACES OF STEAM ENGINES.

THIS Lubricator is very simple, efficacious, requires little attention, has no mechanism to be deranged, effects a great saving of the Lubricant, and a reduction of friction, and consequently of the working faces exposed to the steam. It is applicable to every form of Steam Engines, Marine, Stationary, Locomotive, and Agricultural, Steam Hammers, and other Machines actuated directly by Steam. Prices, 26s. 6d., 35s. 6d., 45s. 6d. Particulars to be had of the Manufacturer, **J. CASARTELLI, 43, Market-street, Manchester.**

No Fitter or Turner should be without a Straight-edge.

The most reliable tool of this kind, graduated to the Standard Measure of the Realm, and manufactured with MARVELLOUS ACCURACY, may be obtained of

**RICHARD LLOYD,
MILL AND MACHINE IRONMONGER
135, STEELHOUSE LANE, BIRMINGHAM.**

Clubs of Workmen supplied at reduced prices. No equal tool is sold under FOUR TIMES THE PRICE.

CHANGE WHEELS FOR SCREW-CUTTING LATHES.

NOTICE TO INVENTORS.—Office for Patents, 4, Trafalgar-square, Charing-cross. Printed instructions (gratis) as to the Cost of PATENTS, for Great Britain or foreign countries. Advice and assistance in disposing of or working inventions. Branch offices and agencies in every Continental State and in America. Established 30 years. Full information as to expired or existing Patents at home or abroad. Apply personally or by letter to Messrs. PRINCE and Co. Patent Office, 4, TRAFALGAR-SQUARE, CHARING-CROSS, W.C.

TO INVENTORS.—GENERAL PATENT OFFICES.—L. de FONTAINEMOREAU, 4, South-street, Finsbury, London; 16, Rue de la Middelité, Paris; 32, Rue des Minimes, Bruxelles. Provisional protection, 27; to complete patent, £30; French patent, £2 10s.; Belgium, £2 10s. Circular gratis on application.

INVENTIONS PROTECTED BY PATENT OR REGISTRATION, at fixed and most moderate charges. The Inventors' Manual free by post, or gratis on application.—Apply to Mr. BREWER (late Barlow and Co.), 89, Chancery-lane, London, W.C. Established 21 years.

INVENTORS ASSISTED IN Securing, Carrying Out, and Disposing of their Inventions.—Apply to Messrs. B. BROWN and Co., British and Foreign Patent Office, 49, King William-street, London-bridge.
A Pamphlet gratis, on Cost of Patents, may be had on application.

INVENTIONS secured by Patent or Registration, on moderate terms, by application to Mr. WILLIAM BROOKES (of upwards of 25 years' experience in such matters), British and Foreign Patent Agency, 63, Chancery-lane, London, W.C.

PATENTS FOR INVENTIONS.—Full instructions may be obtained by applying to Mr. W. T. RAWLW, Office of British and Foreign Patents, 3, Small street, Bristol.

THE LONDON DRAWING ASSOCIATION for supplying Engineering, Mechanical, Architectural, and General Drawing, Designs, Maps, Plans, Tracings, Wood Engraving, Electrotyping, 7, Duke-street, Adelphi, London. Enclose stamp for prospectus.

NOTICE.—Removing to No. 122, from 132, LONG ACRE, LONDON, W.C.—C. SUFFELL, Manufacturer of Improved Engineering, Surveying, and Drawing Instruments for Home or Foreign service. Every instrument of the finest quality at very reduced prices. Standard Measures of all Nations. Post-free Catalogues. Forwarded to all parts on remittance or London reference.

JOHN SHEPPARD, of 10, Maresden-square, Manchester, has specially adapted himself for the supply of **ENGINE-CLEANING WASTE**, at the following prices: White at 2s. per ton; gray, £35 per ton; coloured, £41 per ton. Wadding Material, for wedding manufacturers, at equally low prices, in bleached, crimson, grey, and black. Liberal terms to shippers.

THE LENOIR GAS ENGINE.—A number of these useful and economical engines to be seen in actual work in town and country. Being free from all danger, they can be used where steam power is totally inadmissible. Exhibition, and every information supplied at 40, Cranbourn-street, Leicester-square, W.C.

COPY YOUR LETTERS.—HENDRY'S GUINEA COPIING PRESS, with force, the cheapest and best ever offered, to be had from W. T. HENDRY and Co., Engineers 73, Queen-street, Chancery-lane.

HOLLOWAY'S PILLS.—NERVOUS DEBILITY.—Persons who feel weak, low, and nervous, may rest assured some serious ailment is looming in the distance, against which immediate action should be taken. Holloway's Pills present the ready means of existing energetic action on the liver, liberating accumulated bile, and lifting at once a load from the spirits, and expelling a poison from the body. This simple and natural method of remedying the first tendency to disease gives present ease and ensures future safety. The pills and all those who are losing flesh should try these pills, which are especially useful when the digestive, and other functions are imperfectly performed, and demand immediate correction, or in after years neither mind nor body will be well developed.

PATENT HOLLOW STEAM PACKING.

THE great and peculiar advantages of this packing consist in its remaining perfectly elastic, and is so constructed and applied that the pressure of the steam itself makes the joint by entering the packing from the cylinder; thus the many objections to packing previously existing are effectually removed. Vulcanised India-rubber Sheet Washers, Valves, Springs, Hose, Glazed and Solid Tubing for Gas, Speaking Tubes, Diving Dresses, Gas Bags, Air-proof Goods, or any description of India-rubber articles made to order.

Price list or circular, with full description of packing, to be had of the only Manufacturers and Patentees of Hollow Steam Packing.

FOSTER and WILLIAMS, India-rubber Works, Cowper-street, City-road.

EAST TEMPLE CHAMBERS, WHITE-

FRIARS STREET, LONDON, E.C.

THE EVAPORATER SURFACE CONDENSER (PERKINS'S PATENT).—This simple apparatus, having now been in use for some years, can be strongly recommended as very effective and economical.

A vacuum of 26 in. can be readily obtained by evaporation alone, and all the water now required for the ordinary condenser is dispensed with entirely, and pure water is returned to the boiler, thus voiding all sediment, &c. In non-condensing engines the water is returned to the boilers at a temperature of 212 deg.; and, by the addition of a donkey air-pump, all the advantages of a condensing engine is obtained.

References and estimates given on application to the Manufacturer and Patentee, A. M. PERKINS, 6, Seaford-street, Regent's-square, London, W.C.

PRIZE MEDALS.

INTERNATIONAL EXHIBITION, CLASS I. AND II.

PATENT PLUMBAGO CRUCIBLES.—

The Crucibles manufactured by the PATENT PLUMBAGO CRUCIBLE COMPANY are the ONLY kind for which a MEDAL has been AWARDED, and are now used exclusively by the English, Australian, and Indian Mints; the French, Russian, and other Continental Mints; the Royal Arsenal of Woolwich, Brest, and Toulon, &c. &c.; and have been adopted by most of the large Engineers, Brass Founders, and Refiners in this country and abroad. The great superiority of these Melting Pots consists in their capability of melting on an average Forty Pourings of the most difficult metals, and a still greater number of those of an ordinary character, some of them having actually reached the extraordinary number of 96 meltings.

They are unaffected by change of temperature, never crack, and become heated much more rapidly than any other crucibles. In consequence of their great durability the saving of waste is also very considerable.

The Company have recently introduced Crucibles especially adapted for the following purposes, viz.:—MALLEABLE IRON MELTING, the average working of which has proved to be about SEVEN DAYS; STEEL MELTING, which are found to SAVE NEARLY A TON AND A HALF OF FUEL TO EVERY TON OF STEEL FUSED; and for ZINC MELTING, lasting much longer than the ordinary Iron pots, and saving the great loss which arises from mixture with iron.

The Patent Plumbago Crucible Company likewise manufacture and import Clay Crucibles, Muffles, Portable Furnaces, &c., Stove Backs, all descriptions of Fire Standing goods, and every requisite for the Assayer and Dentist. For Lists, Testimonials, &c., apply to **THE PATENT PLUMBAGO CRUCIBLE COMPANY, BATTERSEA WORKS, LONDON S.W.**

LLEWELLINS & JAMES,

COPPERSMITHS, AND ENGINEERS,

BRISTOL

Sole Makers of Clements'

ECONOMIC LUBRICATOR,

FOR MARINE, LOCO, AND FIXED STEAM-ENGINES.

(As supplied to the Admiralty, and many Engineering and Steamship Companies.)

This Lubricator offers a perfect method of lubricating all the internal parts of the steam-engine, by the vaporisation of the lubricant, saving, at least, half of the oil or tallow generally used, and lessening the "wear and tear" consequent upon imperfect lubrication.

PRICES, COMPLETE, WITH GUN-METAL FITTINGS:—

2 Pints, 62s. 6d.; 3 Pints, 67s. 6d.; 4 Pints, 75s.

BRIGHT GUN-METAL BODIES, EXTRA.

As they are fixed on the steam-pipe, the diameter of this should be given; and it should also be stated whether horizontal or vertical.

BRITISH AND FOREIGN PATENTS AND THE REGISTRATION OF DESIGNS.

Mr. H. H. MURDOCH having succeeded to the business of his late Father, which has been established upwards of Thirty Years, offers his professional services to inventors. A circular, containing full information respecting the various modes of securing protection for inventions at home and abroad, may be had, Gratis, by applying (personally or by letter), at his OFFICE FOR PATENTS, 7, STAPLE INN, LONDON.

PATENTS.

FIG. 3.

IMPROVEMENTS IN TELEGRAPH CABLES.

OUR attention having been directed to Mulholland's improvements in the construction of deep-sea telegraph cables, and method of laying same, and knowing the vast amount of interest attaching to the subject, we this week take the opportunity of calling attention to the matter.

To briefly, yet distinctly, point out the main characteristics of Mr. Mulholland's invention, it is necessary to refer to the engraving, in which Fig. 1 is a full size transverse section of a 5-core cable: A, representing one of the insulated conductors; B, the fibrous or green hide, serving or braiding over same; and C, the wire sheathing or external protective envelope. This diagram explains the arrangement of the several parts and method of construction, the patentee's object being to combine any number of conductors in a flat rope, the selection of form being governed by the admitted superiority of that shape for mining purposes, both as regards the additional strength gained and great saving of expense in manufacture, combined with durability, superior lightness, and capability of withstanding strains. Hence, it appears that by preferentially adopting the form of a flat instead of round rope, it is practi-

cable to construct a cable which it is claimed is superior, both mechanically and electrically, to that recently lost, and admitting the cost of laying to be the same (although such would not be the case, as no brake machinery is required, and the method of paying out or hauling in essentially different to those hitherto practised in submerging cables in deep water *without injury to the insulation*), claim that sixty instead of twelve words can be signalled per minute, must unquestionably interest intending shareholders, in any scheme of transatlantic telegraphic communication. Fig. 2 shows a single conductor in section *enlarged five times*. A is a chemically pure copper wire, varying from 12 to 16 B.W.G. (according to circumstances), the surface being carefully de-oxidised before coating with an insulating compound; B, pure india-rubber tape, immersed in phosphorised composition, wound tightly round the wire and passed through shaping rollers to ensure uniformity of size and homogeneity of the several parts (this process of manufacture causing the layers of caoutchouc to adhere to the already insulated conductor); C, two or more coatings of composition laid on at intervals to ensure perfect insulation; D,

special compound of non-conducting material uniting the several cores; E, protective braiding of hemp or green hide, saturated with the composition, and shaped in rollers prior to receiving the wire sheathing. The cable, on completion, and previous to being stowed for service, is passed slowly through troughs of the composition to prevent oxidation of the wires, and (as the compound acts in a few minutes) it receives a final coating immediately prior to immersion. Fig. 3 is a longitudinal section of the after part of a vessel assumed to be specially fitted for telegraphic purposes; A, centre of gravity; B, a water-tight sheath or tube over an opening cut through the bottom of the ship, as near the keelson as possible; C, C, C, the cable; D, a drum or whimsey on the upper deck, being the point of contact upon which the cable impinges on its road to the delivery tube; E, E, guide rollers, fitted with lever nippers (not shown) to retard the delivery of cable if necessary while paying out; F, engine room; G, coal bunkers; H, boiler room; J, upper deck; and K, line of keel when vessel is pitching by the head. Fig. 4, represents the midship section of a ship rolling to port or starboard in a heavy

seaway, showing the centre of gravity at A and the cable B, B, paying itself out under any circumstances in still water, while the vessel is running at full speed under sail or steam, or both combined.

It is admittedly sometimes a more fatal mistake to underrate than to over estimate the merits of any particular invention, and finding as noticed by us in No. 10, Vol I., that a patent has recently been taken out in Paris, (and the discovery highly eulogised by the continental press) for the application of phosphorus as a preservative "from the attacks of those agents that ordinarily effect the destruction of iron," we must in this particular instance admit our countryman's claim to priority of invention, his patent being dated September 1863. It appears that in the South Atlantic and Pacific Oceans vast submarine forests of the "Fucus maximus" are met with growing from insignificantly sized rootlets at depths of 70 and even 100 fathoms with straight smooth stems 1 to 1½ in. in diameter until they reach the surface, and these are invariably so strong and pliant that they resist with impunity the action of the mightiest breakers in the world. Observation revealing the fact that neither Remora Crustacea or animalcula of any kind penetrate or even adhere to the polished exteriors of these singular vegetable ropes, and subsequent analysis proving inconceivably the richness of the fucus in question, to be composed of rich in phosphoric acid. The patentee claims to have discovered a chemical agent not subject to decomposition by organic or inorganic matter, therefore a true preservative from the action of sea water. Hence the origin of the compounds, the application of which the inventor advocates as protectives to metal and timber from marine or atmospheric action, and consequently from the amount of constituent phosphorus they contain to be peculiarly adaptable for submarine telegraphic purposes generally, when combined with carefully selected materials to insure homogeneity and durability, objects of paramount importance and consideration evidenced by the case bestowed upon the drawing of the patent specification.

AMERICAN PATENTS.

COMBINED FRICTION WHEEL AND OIL CHAMBER.—This invention is more especially intended for railroad car brakes, but is also applicable to other machinery to which power is transmitted through the medium of a friction wheel. It consists in combining with a friction wheel an oil chamber arranged in such a manner that the former will always be kept in a perfect state of lubrication, the importance of which, in connection with a friction wheel for transmitting power, may be easily imagined. A. I. Ambler, of Chicago, Ill., is the inventor.

STEAM TRAP.—The object of this invention has been to make a steam-trap for the discharge of the water of condensation from steam pipes and vessels, automatic under all circumstances and of the utmost simplicity in its construction. The water received in a metallic casing through the bottom of which is passed a pipe closed at its top, and perforated with a series of holes at a small distance above the bottom of the casing. An open vessel, in shape like an ordinary pail, but having a collar fitting around and extending a short distance above an opening through the centre of its bottom, fits over the pipe, and its collar acts as a moveable seat, to the perforation in the pipe. This collar or valve seat covers the valves when the float is at rest, and uncovers them when it is in motion, so as to discharge the water. Peter Hogg, of New York City, is the inventor.

OIL EJECTOR.—This invention consists in closing the bottom of a well tube in which an oil ejector is used, and placing a valve therein below the embouchure of the ejector. The effect of this construction is to prevent the pressure of the currents of fluid or liquid delivered into the tube from the ejector from acting upon the gaseous or liquid contents of the well, and so to relieve the packing and also the gases and liquids in the surrounding rock from such pressure. By means of this invention the whole energy of the currents which pass through the ejector is used directly to lift the columns of gases and liquids in the well tube, and none of it is allowed to react against the packing or against the incoming oil and gases. F. S. Pease, of Buffalo, N. Y., is the inventor.

BARON SQUIER has discovered that if a glass cylinder be plunged vertically into a vessel of water in such a way that a part of it will be in and a part above the water, and a ball of lead is allowed to fall within it, along its axis, the glass will be cut horizontally on a level with the surface of the water, the part below being broken in pieces longitudinally. The effect is due to the incompressibility of the water.

ANSWERS TO CORRESPONDENTS.

B. O. E. (Dowlais).—Send for Spon's catalogue, and you can select therefrom to suit your pocket.
GEORGIOUS.—Yes, you can get all in, easily—but be careful. (2) Not wanted in Provisional, but mechanical drawings required with Complete: must, in your case. We wish you every success.
G. F. W. (Liverpool).—Notice partially withdrawn.
R. B.—We will try what we can to oblige you.
INDICATOR.—Spon publishes a book at 4s., by Main and Brown, on the "Indicator and Dynamometer, with their Practical Application to the Steam Engine." Also, one by O. T. Porter, price 2s.
T. HOLROYD.—There is no special work that we know of, but we have inserted your query elsewhere. (2) "Heat," by Colburn, 2s.; Spon; Scott Russell, on the "Nature, Properties, and Application of Steam," 2s., Spon. Also, a work in two vols, by C. W. Williams, on "Steam and its Production," which Spon could furnish you with, doubtless.
A. W. FORBES (Edinburgh).—Received. Best thanks; the subject is pretty well known, and we believe there are several patents out for it.
P. P.—Received. Would advise you not to waste your time. Wait till the circle is squared.
SHEFFIELD.—Your complaint of not having received the "Guide" has been forwarded to the address of the writer.
S. J. B.—We think the invention a very good one—especially the grip and leverage. Try the one or two makers of cables—whose address in London Directory; if that will not do, try and get an opinion from one or two men of science, and with them in hand, advertise a little for a capitalist to purchase the patent.
TELEGRAPHIC.—You will readily find it in the Post-office Directory at your own shop. We think he may be found at the works at Greenwich.
JAMES BROWN.—Many thanks for your kind letter. The title cannot now be altered, as you say—but what's in a name? We have kept a "query" in for you, in its place. Perpetual motion is a fudge, and we have stopped communications; any communications after it simply wastes brain, tissue, and time. Send us up your wood-cutting scheme.

*. We have to ask our correspondents to so sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them by the thousand; the same with "Well-Wisher," &c. If they don't like to see their own names paraded, use those of an ancient or any other man.
 Several letters remain over till next week for answer.
 Letters applying for information to be furnished by post cannot be attended to.
 Correspondents are requested to keep copies of their drawings and manuscripts, as the Editor cannot undertake to return such as may be rejected.

THE WILSON FURNACE.

The object of this furnace is a saving of fuel and the consumption of smoke; and it is attained by—contrary to the usual practice—burning the fuel downwards or inwards, instead of from the lower surface upwards. For this purpose furnace-bars are dispensed with; and instead of the usual feed door, there is an aperture at the top of the furnace, through which alone both the fuel and air are supplied, and which can be easily opened or closed, as may be found requisite. The coal, which is in small pieces, falls from the opening along a curved inclined plane, descending according as the lower portion is consumed. The volatile products given off by the heated coal are carried down, along with the oxygen required for their combustion, by the draft, through that portion of the fuel which is in a state of intense ignition, and consumed; thus greatly augmenting the heat and economising the fuel. As the furnace is self-feeding, it is only necessary to keep the hopper at the top supplied. The invention seems applicable, at a small cost, to existing furnaces, &c.

TIN PLATE POISONOUS.—It is usually believed that the tin with which the sheet iron used in saucepans and other domestic utensils are covered is harmless; and that what is employed as a coating for copper vessels is not only an absolute protection against the dangerous properties of the copper, but is itself a perfectly harmless addition. Such was the case formerly, but to suppose it so at present would be a dangerous mistake. In this time of violent competition among manufacturers, and unbounded desire of gain, no mode of adulteration, however mischievous to the consumer, is considered culpable, provided it increases the profit of the seller. Lead, as is well known, is capable of giving rise to the most deleterious compounds; and, unfortunately, cases of lead poisoning have frequently occurred of late from the use of tinned tea-kettles and saucepans. This arises from the tin used in coating the sheet iron having been largely mixed with lead, a far cheaper metal—an adulteration of tin which is extremely common. The fact will, when generally known, lead to the more general use of enamelled articles; especially when substances containing constituents likely to act on metals are to be heated in them.

NOTICE TO ADVERTISERS.

ADVERTISERS in this journal are respectfully informed that the Collector from the office, 162, Fleet-street, will call upon them for a settlement of the amounts due for the insertion of advertisements. The Collector will in every instance hand in a printed receipt for the sum paid to him. Advertisers are particularly cautioned against paying money without receiving the printed receipt.

THE ENGLISH MECHANIC!

Just Ready, and now Publishing, the
FIRST VOLUME

of
THE ENGLISH MECHANIC,
A Record of Mechanical Invention, Scientific, and Industrial Progress.

UPWARDS OF ONE HUNDRED
ILLUSTRATIONS.

Handsomely bound, only 4s. 6d.; post free, 5s.
GEORGE MADDICK, 162, FLEET-STREET, LONDON,
and all Booksellers.

THE ENGLISH MECHANIC.

Every Tuesday, One Penny. Monthly Parts, 5d.
Now Publishing, complete, the First Volume.
. Title Page and Index, One Penny. Cases for binding, One Shilling and Sixpence.
It is solicited that all back Numbers be ordered at once.

All the early Numbers have been reprinted. It is therefore necessary that sets be made up at once, as there will be no further reprints owing to the great expense they entail.

162, FLEET-STREET, LONDON, and all Booksellers.

TO ADVERTISERS AND CORRESPONDENTS.

. In future all Advertisements and Communications for the Editor to be sent to
162, FLEET-STREET.

OUR MONTHLY PARTS.

Part 6 of THE ENGLISH MECHANIC, in coloured wrapper, is now ready.

Price 6d. only! Post free, 7d.

All back Nos. have been reprinted, and can be had direct from our Office, or through any bookseller.

TO ADVERTISERS.

As the ENGLISH MECHANIC addresses itself to the largest and most intelligent portion of the community, and is the only Paper of the kind established, it offers unusual advantages as an advertising medium.

SCALE FOR ADVERTISEMENTS:

	£	s.	d.
Five Lines	...	0	8
Every additional Line (Nine Words)	...	0	6
Whole Page	...	8	0
Half Page	...	4	0
One column	...	3	0
Post-office Orders to be made payable to GEORGE MADDICK, Fleet Street Branch.			
All Advertisements should be sent to us not later than Friday.			

The English Mechanic.

FRIDAY, OCTOBER 20TH, 1865.

TRADES UNIONS AT THE SOCIAL SCIENCE CONGRESS.

AS might have been expected, the subject of trades unions and strikes occupied no inconsiderable share of attention in Sheffield during the recent Congress, and it was led off in the Department of Economy and Trade by Mr. Wilson, a pen-grinder, with a paper entitled, "On Tradesmen's Strikes and Lock-outs, and Courts of Arbitration and Conciliation." He commenced by pointing out that close combinations maintained a high rate of wages, and because this was done on a limited scale the unionists believed that it could be accomplished universally; but the unionists only succeeded by restricting their number; and this view was taken by Mr. Stuart Mill. He argued that the system of restricting employers from taking more than a certain number of apprentices prevented a father from putting his son to a trade better than his own. Some trades were better suited for successful combinations than others, and high wages were obtained; but if the men were not allowed to compete

in the best paid trades they were driven to the worst, in which trades consequently wages remained at starvation point. After quoting extensively from Mr. Stuart Mill, Mr. Wilson went on to point out that labour was an operation, a power directed by a design, and perfected by moral culture and intellectual study. No one wanted to purchase the labour, but its product; and after selling the "product" a man retained his labour. He then reviewed recent strikes and their causes, and said that in all those cases the men were met by lockouts, and the capitalists were successful and the men suffered. To obviate this state of chronic antagonism between different trades, he believed courts of arbitration were impracticable. He believed trades unions and strikes would work their own cure. He did not remember two strikes in any one trade, as, by suffering, men learned wisdom. The men were in favour of arbitration courts; but surely if a man could sell a pig, or the produce of his garden, or had the choice of a wife, he could sell his labour without the interference of third parties. The right of buyers and sellers was to be free, and what could compulsory arbitration do unless they could compel men to employ their capital in a particular way? No court could be as successful as a settlement between the masters and men themselves. A strike and lock-out placed both parties in a false position, as neither party could act without consulting the executive committee, which frequently prevented a settlement between the master and men; and the doctrine of non-intervention proved the true one. Men had a perfect right to combine, but not to coerce those who did not join the combination.

Mr. Wilson made one or two good "points," but did not seem to carry his audience well with him.

Mr. Frederick Hill said that whatever faults might have been committed by the working classes they were not alone in the matter, for all concerned in the legislation of the country must take upon themselves no inconsiderable share of the fault which had led to such disastrous consequences as those which had taken place.

Mr. Dronfield, an operative, expressed his belief that, as it was very easy to throw dirt, so abuse had been heaped pell-mell on Unions, and their members. He called attention to the state of the law which made it an offence punishable by imprisonment for a man to break his contract, whereas, if the employer broke his, he was only liable to a civil action. Trades unions, he said, did not devote all their energies to stirring up disturbances and keeping up strikes, and instanced the many benefits accruing to their members in libraries, unemployed money, and funds to meet sickness and death. It was seldom, he said, that a member of a trades union had to seek parochial relief. Professor Fawcett, M.P., thought working men had a most undisputed right to combine, if they could support that combination without practising coercion. In consequence of the existing economic relations between the labourer and the employer not being satisfactory, these combinations were necessary, presuming there was no coercion, in order to give the labourer the greatest possible price which he could obtain for his labour. By joining and combining, artisans were more likely to get a satisfactory bargain than they would if they did not combine. But let not labourers make any mistake about what they could obtain by these combinations. Unjust demands had been made upon the masters in some cases, but whatever injury was thereby inflicted upon the masters the injury falling on the working men was greater. Therefore the justice of the cause should be well ascertained before combinations were organised.

Amongst other gentlemen who took part in the discussion were Mr. David Chadwick, Mr. Edwin Chadwick, Mr. Channing, and others. Mr. Thomas Hughes, M.P., was to have taken part in the discussion in this department, but he was unable from some cause to be present.

At the working men's gathering on Thursday evening three of the speeches were of special interest, from the fact that the speakers were all young members of the Parliament just elected, owing their election in some measure to the favour of working men. Their remarks, therefore, might fairly be regarded as indicating by anticipation the course which, on particular questions, they were likely to adopt in the House of Commons. Mr. Chambers spoke with the earnestness and fluency which secure for his remarks a favourable hearing from public assemblies, and, insisting on the advantages of education, he so adapted his arguments and illustrations to the audience he was addressing that at every few sentences he was interrupted by their acclamations. Mr. Hughes marked out for himself a different line, running *contrà* to the feelings of his auditory in a very remarkable manner, and to an extent that re-

quired, even from him, no ordinary amount of daring. Speaking in the very central district and stronghold of trades unions, he did not shrink from using such language as the following:—

"The difficulty which had stood in his way was that this had been constantly thrown in his teeth—'Oh, have you heard of the last trade outrage in Sheffield? Have you heard that a house has been blown up with gunpowder, and that another man's wife and child had been attacked because he did not—'. Did not what? 'Because he did not obey the laws of a union of which he was not even a member?' If trades unions were to fight the battle of the working men they must set their faces against practices such as this. Let them say, 'These outrages are things of the past; in the future you shall hear no more of them; we shall fight our battles henceforth in an honourable, straightforward, and Christian manner.' He had heard a few things of Sheffield. The men of this town lived in the very heart, in the midst of the intelligence of England, and as working men they received the highest rate of wages, and yet he was told they were opposed to the introduction of machinery, whereby they were driving away from the town a large branch of industry for which they had been celebrated for hundreds of years. (General cries of 'No, no,' and 'Order.') Well, he was brought up in an agricultural district, and was just old enough to remember the machine breaking which took place in that part of the country. Those acts of folly produced a sad amount of destitution and misery; but by-and-bye the men found out their mistake, and now there were reaping machines and threshing-machines working all through the district, and what was the result? That wages had risen 50 per cent. since the introduction of machinery. He would warn the men of Sheffield, if they were opposed to machinery, that there could be only one result—that they would drive the industry of the town into towns where the men were not so short-sighted.

"He heard that there were rests used, the use of which was enforced by the trade, but the effect of which was to double up the man's arm and make it useless after a few years, while they had a rest which produced no such results, and which, if used, would enable a man to work ten, fifteen, or twenty years longer. If that were not true, let them contradict it. To his mind it was necessary that he should in this great centre of trades unions, where they had it nearly all their own way, tell them the plain truth; and in so doing he repeated, with regard to machinery, that if what he had heard were true, they had adopted a course by which they would gradually lose the confidence of the best part of their fellow-countrymen, and by which they would not hold their own in the great industrial race of the country, unless the men confined trades unions to laying down laws for their own members, and did not meddle with those outside."

The delivery of these sentences coming, above all, from the quarter from which they proceeded, exercised an effect upon the body of the assembly very much as if a live shell had dropped into their midst.

The speech immediately following that of Mr. Hughes was in very different tone and temper. This was delivered by Professor Fawcett, who apparently thinking that the working men required some soothing words after what had just been said in their presence, entered upon a glowing description of what the condition of the workman should be as distinguished from what it is. The speech was able, fluent, adapted in most respects to the taste and peculiarly to the prejudices of the class to whom it was intended, but it is doing no injustice to Professor Fawcett to add that in the opinion of warm friends of the Association, even of his own, the power for good of Social Science Congresses would soon be at an end if such harangues to the operative classes were habitually indulged in from these annual platforms.

Mr. J. CHUBB has just invented a method of securing safe doors from the application of the professional burglar's wedge. The frame, in place of being made flush as hitherto, projects beyond the door, so that the door will be recessed; and further, to protect the door and the keyhole or holes through the door of a strong room or iron safe, a hardened steel bar is applied externally to the door, and from side to side thereof, the bar being fitted within a groove across the door. This bar is of a curved convex form externally, and flat on the side where it comes next the door. At each side of the framing of the door a projecting socket is formed, into which the bar slides after the door has been shut and fastened or locked. In order better to insure that no thin steel wedges shall be introduced, the sides of the groove across the door in which the bar is fitted are under cut.

LETTERS TO THE EDITOR

[We do not hold ourselves responsible for the opinions of our correspondents.]

EXPLOSIONS IN STEAM BOILERS.

Sir,—A subscriber from the first I have been, and hope still to be, delighted with my weekly pennyworth—*THE ENGLISH MECHANIC*. I am only a stoker, but I can understand a great deal of what is set before me in your paper, by yourself and your correspondents, whom I have had to thank for information once or twice. There is one correspondent who signs himself "F. M." a new member of the "Correspondence Club," who, in my opinion—if that is worth anything—had better leave off writing on boilers until he knows something about them. His writing is "one of the things no fellow (in my line) understand;" and I don't think he's too sure about it himself.

I always notice that the less a man knows about a thing, in which he would like to dabble, the more he goes "supposing" and "guessing," and making what he is pleased to call "theory" do duty for "practice." I don't say "F. M." does this; but what he does is very like it. He says that the majority of explosions are shrouded in mystery. Well, if he writes of the appearances their particulars present to himself I am not qualified to doubt, but if he thinks to express my opinion in his declaration, I can tell him he is—well, he is utterly wrong. I am no better informed, perhaps, than many other stokers, and yet I don't remember ever having heard of an explosion which could not be accounted for, if the parties "interested" would only speak out. Now, down here, we have the Steam Boiler Association, and Mr. Fletcher never experiences any difficulty in giving a "why" or a "wherefore" in every case submitted to him; and that being the case, it is evident to any thinking man that such explosions are preventable; consequently, that what they are shrouded in at the time of an explosion is not mystery by a long chalk.

More than that, it is shown by the officers of the Association, and by the boilers they look after, that there is no mystery in the matter, and that care and attention are the only things necessary to keep a boiler in long life.

If "F. M." will get hold of the reports of this Association he will find everything very clearly accounted for; and he ought to know that a coroner's inquest is scarcely the place in which to find light thrown on a subject, constituted as some of these assemblies are. "F. M." has not asked for any information on the subject, but in case he should, I would ask him to canvass among the shops here for the opinions of stokers and engineers. I am sure he would think twice after that before he thought of asking you for more room, and to be put in big type.

I can't say I've studied the growth of steam over a fire; and perhaps "Mr. F. M." is right in what he says about that. I have heard before that perhaps gas from the exterior could penetrate the boiler shell, and give fits to its contents; this I should imagine could be done by subjecting it to a terrific pressure; but as this is not done in daily practice, I fancy that any gas which may penetrate to the outside of a boiler is rapidly driven away again, up aloft, or drawn by draught under the bars, through the fire, and turned into the air as something else. But, there, I'm almost getting as—as shrouded in mystery as "F. M." who takes longer in working to a point than did another "F. M."—"The Duke," and therefore I will leave off, as my "turn" at stoking begins shortly. And I'm only repeating what my mate and the other "shift" say, when I express to you the hope that the next correspondent who lays hold of a boiler for a subject will be careful what he is about, and not subject himself to a "blow up," though, mayhap, he might see a "flash of lightning" during the operation.

H. REYNOLDS.

Manchester, October 7, 1865.

[Our correspondent will observe that we have struck out a considerable portion of his letter, including the "personal" matter. Such cannot be allowed entry into our columns; and has never yet advanced a discussion one step in the right direction.—Ed. E. M.]

BOOKS ON TURNING.

Sir,—Allow me to express the gratification I have derived from perusing the list of "Books on Turning," by "H. H." in your paper of Oct. 6th, a list I have long sought for in vain. I heartily wish that some competent person would take the hint dropped by "H. H." and compile a work on Turning "worthy of being reckoned as the continuation of Holtzapffel's great work." It is a reproach to a country like England where the mechanical arts have attained unrivalled perfection, that at the present time we are positively without a good English book on plain and fancy turning. From my knowledge of the English works on turning, I am able fully to endorse the strictures which "H. H." makes regarding most of them. Some of the French works are far superior to anything published in this country, but it is evident that the language in which they are written will be an effectual barrier to their general use in England.

I sincerely hope that among your numerous and talented contributors there may be some gentlemen able and willing to compile a work on turning, such as Charles Holtzapffel would have written had his valuable life been spared. Perhaps "H. H." himself would undertake the task, but by whomsoever undertaken it should be regarded as a "labour of love."

A book worthy of the subject would be hailed with delight by thousands of turners, and especially so by S. H. P. E. Will "H. H." kindly furnish me with the price of Captain James Ash's work on turning, numbered 26 in the list, and also the address of L. Booth, the publisher.

ECCENTRIC CHUCK.

Sir,—I observe that some of your correspondent amateurs want to make an eccentric chuck. Some years ago when making amateurs apparatus I made an improved chuck that would either do for an oval or eccentric one.

A tracing of the drawing of this chuck I will present to any mechanical amateur, or you may insert it in your magazine if you think it worth your while.

WM. MUM.

[We shall feel greatly obliged if our correspondent will forward the tracing to us.—ED. E. M.]

OUR SUBSCRIBERS' NOTES AND QUERRIES.

SAWING TIMBER.—Where can I, in London, or close to it, see a machine for sawing timber driven by horse-power?—M. WILLIAMS.

ELECTRIC LIGHT.—Will any one tell me how I can get a steady light of this character?—MILLWALL.

OIL GILDING.—Wanted to know, the best method of oil gilding on wood and iron.—J. S. G.

BLACKING SHEET TIN.—How can I best bronze or varnish sheet tin black so it won't rub off?—V. V. E.

LATHES FOR NAILS.—Wanted: a description of a lathe for making small screw nails for iron?—MECHANIC.

FLUXES.—I want to make a zinc pan 18 inches deep, 3 feet over at top, 8 inches at bottom, to be made in three pieces—wanted, the rule for cutting it.—HAND CHISEL.

SPOILING TOOLS.—How is it that, when repairing cast-steel tools, if heated above a dull red heat, they are spoilt, though they have previously been exposed to almost a melting heat?—H. C.

OIL FOR CLOCKS.—Which is the best, and how is it refined?—E. FEATHER.

COILS, &c.—The best place to buy copper wire, also the silk used in constructing electrical machines? What conditions must be observed in covering the wire, and why it must be covered? Must secondary coils as well as primary ones be covered? This for a guide in constructing a covering machine.—T. PARKER.

PERSPECTIVE.—The best method of finding the point of sight and the perspective plane, or plane of delineation in perspective, and also the best position for the point of sight on the drawing?—A. SUB.

"SPIRITUAL" MECHANICS.—J. B. (Glasgow), wishes information respecting the *modus operandi* of the so-called spirit-rappers, including the Davenport and Mr. Home. He thinks a diffusion of knowledge on this subject would tend to good.

MAGNESIUM.—Can any one tell me of a book on magnesium, its nature, properties, and appliances?—T. HOLROYD.

WATER POWER.—Can any one inform me by what mechanical means a fall of water, seven feet, running at fifteen gallons per minute, can be made to raise a column of water in a $\frac{1}{2}$ -inch pipe to a height of twenty yards?—FRED.

FRICTION GEARING.—Can any one inform me of a good plan of friction gear to wind both ways with engine running—the gear to be put in and out as required?—O. E. A. (Sheffield).

[We think a Glasgow firm supplies this on their own patent.—Robertson and Company, we think, but are not sure.]

PUMP.—The cheapest way of making a force pump for an ordinary-sized garden engine—length of stroke and diameters of cylinder and valve.—C. R. FISCH.

DENSITY OF EARTH.—Can any one give me the formula for finding the mean density of the earth by means of the number of vibrations which a pendulum makes in a given time.—W. H. E. RICHARDS, (of the Round Head).

[Here let me thank Mr. Parkinson for his kind offer. Mr. Hart, of Edinburgh, has kindly supplied my wants.]

BALTING.—Where can I get machine belting $\frac{1}{4}$ inch wide that will remain flexible, and the cost?—PNEUMATIC.

SCREW THREADS.—Is there any difference as to power in screws of one thread only, and those of same diameter and pitch, but with two or more threads?—TWO.

FALLING FORCE.—A steam hammer weighing 5 cwt. falls through 20 inches its own weight; what is the amount of force or weight impacted on the object operated on, and what amount of dead weight pressure would do the same?—T. Y.

NAILS.—Who makes machines for making iron wire nails, such as made and used on the Continent?—E. O.

MICROSCOPE LENS.—Will any of your readers inform me how microscope lens are ground, polished, and centered?—D. K.

SPECTULUM.—I have a 4 inch Gregorian speculum, whose figure I fear I injured by attempting to polish it in a common turner's lathe. Its focal length is about 23 inches, with its ordinary little speculum. Can you guide me to a practical workman who could restore its figure and polish?—G. B. G.

I should be extremely obliged if your correspondent "H. H." would inform me through the medium of your valuable paper, the price of the two volumes and atlas of "Bergerson's Manuel de Tournement," and also what English book-seller would supply it?—J. F.

PENDULUM.

Sir,—In No. 26, "J. Newton" enquires what keeps the pendulum of an electric clock in motion. In answer to which, I wish to say that the pendulum bob being made of a reel of insulated copper wire, and the electricity in going through it, it forms an electro-magnet, which is attracted by the permanent bar magnets, which are placed with their similar poles to each other; but a little before the pendulum gets to the end of its stroke, the circuit is broken, and the magnetism of the bob is gone, and the pendulum falls by its own weight. After it has passed the centre of gravity, the circuit is made, and is again attracted by the magnets in the tube, and set at liberty, as before.

Can any reader inform me how the tips of bagatelle cues are put on, and what they are made of?

J. W. MOORE.

POWER OF STEAM.

Sir,—Will you kindly inform me what will be the relative power steam will have upon the various forms of piston surface annexed? They will be pushed forward in the cylinder with varying degrees of force proportionate to the effective area—not superficial extent—offered to the power of the steam; but according to what mechanical law or rule can the force of steam upon a convex or concave surface, for instance, be resolved and compared with its force upon a plain flat surface?

Pressure in every case considered from below.

Taking the upward pressure on a to be the most powerful, and giving it 10 as a standard, in what order would you arrange them with corresponding numbers? From this I wish to gain the principle.

If steam of equal densities be placed above and below E and F, will the pressure on the sides m, n, or m' affect the downward force acting on g, g.

J. E. M.

PRESSURE ON BOILER.

Sir,—In answer to "R. E. Mellor," I beg to present the following formula, as given by W. Fairbairn, Esq.:—

$$C = \frac{DP}{2T}$$

Where C = Thickness of plate.
D = Diameter in inches.
P = Pressure in pounds.
T = Tensile strength of riveted joints.

The working pressure of your boiler being 80 lbs. to the square inch, the bursting pressure should be 400, then 400×12 , and divided by $2 \times 34,000$, the strength of riveted joints would stand thus:—

$$12 \times 400 = 4800$$

$$34,000 \times 2 = 68,000$$

giving .07 inches as bursting power. Hoping this will convey the information required.

ASPIRANT.

BORING AND TURNING CYLINDERS.

Sir,—In answer to "J. H. J'a" inquiry how to bore small brass cylinders; turn a brass chuck to fit the hole already bored out in the cylinder; set it on the chuck about 1-32 in., then tin the chuck and the end of the cylinder, and apply heat to them till they are soldered. Then you can bore and turn the cylinder with one chucking—thus:—

(A is the screw mandril; B, the cylinder, and C, the chuck.)

The boring bit must be flat, 3-16 in. thick, and diameter of holes $\frac{1}{16}$ in. The shank may be of any length of steel. The bit must be packed on each side with wood, with two screws through to hold the wood while being turned the size of the bit. Turn the cylinder out to bit point of boring bit.

GLENLUCK.

PISTON VELOCITY.

Sir,—According to Bourns, the speed of a piston increases as the cube root of the length of the stroke. Supposing a piston, 16 in. dia., 2 feet 6 in. stroke, working at 20 lbs. pressure per square inch, to maintain a velocity of 220 feet per minute; then, by increasing the length of stroke to 5 feet (pressure, diameter of piston, and load, remaining the same), we get by the above rule 277 feet per minute as the increased velocity, due to increased length of stroke, for $\sqrt[3]{2.5} = 1.357$, and $\sqrt[3]{5} = 1.71$, and $1.71 \div 1.357 = 1.26 \times 220 \text{ feet} = 277 \text{ feet}$.

But if "J. T. M." reduces the piston to 8 in. diameter, or only $\frac{1}{2}$ the former area (instead of $\frac{1}{4}$, as he erroneously supposes); then (velocity being directly as the pressure, and inversely as the load) he must either increase the pressure to four times the amount, or 80 lbs. per square inch, to get the same quantity of work done, or reduce the load to one-fourth the amount, to maintain the increased velocity.

JAMES LOTT (Engine Driver).
P.S.—Bourns gives the velocities of ordinary engines at 128 times the cube root of the stroke in feet; but have charge of an engine two feet stroke working 240 feet per minute.

GAS PURIFIER.

Sir,—In answer to "Vesta," his gas purifier having too much pressure, I should recommend him to first examine the dip and syphon of the inlet pipe below the purifier and gas holder, and if these show no more dip than two inches, then he may come to the conclusion that the pipes are partly made up, and require a blast of steam driving through them to remove the tar, &c.; then pump the syphon mentioned above, to make sure, and if that does not eradicate the evil, apply again through the columns of THE ENGLISH MECHANIC.

THOMAS JACKSON.

FALLING BODIES.

Sir,—If the attraction of gravity on two different masses is in proportion to the density or specific gravity of such masses (which I do not dispute), how comes it that a guinea and a feather, the former being, say, 500 times the specific gravity of the latter, let fall from the top of an exhausted receiver, both reach the bottom in the same time? The guinea being impelled, or attracted by, say, 500 times the force acting on the feather?—ought not its velocity to be proportionately increased? An explanation from some of your philosophical readers would greatly oblige

J. L.

LATHES CENTRES.

Sir,—I think there must be some mistake in that given—70°, 80°, and 90°—for lathe centres, 45° being rather the best of the four. I think about 35° is very good, and any one in practice must know that a very long tapered centre is constantly boring into the work, and making it untrue. I beg to offer a sketch of the best working centre. This angle will bear a great weight, without destroying the centre in the work. All centres in work to be turned should be drilled up to keep the work true. It is very often thought that a long tapered centre carries the weight best in turning lathes; and so it would, if the work did not turn on it.

To harden centres: make the tapered part a very red red heat, and cool it in clean water.

Taking the cold chill off water prevents many tools from splitting, and breaking when being hardened.

KILMARNOCK.

COPPER WIRE.

Sir,—I certainly am surprised to see a note from Mr. G. Taylor upon this subject in your last issue and in reply to him; I have had the naked wire gauged by a very delicate pinion gauge, which, by calculation shows the wire to be of the diameter of about .006 of an inch. The gauge by which the number 35 is arrived at is the B.W. gauge.

As to Mr. Scrase being a friend of mine, I desire to inform "G. T." that I never yet saw Mr. Scrase in my life. He is to me as much of a friend as the tailor or bootmaker who undertakes to supply me with a good article at a reasonable price, and it was the desire to enable others to get similarly served that induced me ever to give Mr. Scrase's name.

Now let me interrogate "G. T." a little. May I enquire where he gets his data for the length and weights of copper wire. Mr. W. H. Preece (no mean authority on such matters), in his tables, gives No. 35 copper wire, diameter = .006 inches, weight of one mile = 4012 lbs. Therefore, I would like to know how G. T. finds that 1 lb. of No. 35 only measures 1,500 yards? Perhaps G. T. would like to know how I found about one mile in the pound. It was this:—

I weighed one ounce exactly, and on stretching it out, and measuring, I found about 109 yards in an ounce. I may mention that the Liverpool agent of Messrs. Silver and Co. quoted me No. 35 silk-covered wire at the same price, —12s. 6d. per lb.

Now, if G. T. wishes to split hairs with me, let him say so, and I shall then be compelled again to trespass upon the patience of the Editor, if he will permit it; but I cannot see the necessity of haggling about a point which G. T. might have decided for himself by simple experiment, or by consulting the tables of any recognised authority upon electrical matters.

T. F. WILLIAMS.

LAP AND LEAD.

Str.—In answer to "Eccentric," the following may prove useful:—Let him draw a centre line A, C, across the sheave, through both centres; set off B, D, parallel and equal to the lap+lead of the slide valve (called the lever advance) from centre G, with radius equal to the throw of the valve; describe a radius cutting D, B, in I; draw a straight line from centre G, through T to the circumference F; set G, I, F, at right angles to the crank. The line G, I, F—the angular advance of sheave.

The following is a rule to find the lap and lead of slide valve:—

W = width of one steam port in inches; L = lap in inches; I = lead in inches; S = stroke in inches; T = travel of slide; X, the distance travelled by the piston before the steam is cut off.

$$X = S \left[1 - \left(\frac{2L + I}{T} \right)^2 \right]$$

$$L = \left(\frac{\sqrt{S - X}}{T} \right) - \frac{I}{2}$$

$$T = 2L + 2W.$$

Newcastle, Oct., 1865. JAS. MORRISON.

HARDENING DRILLS.

In reply to "A Watchmaker," (No. 26), I beg to inform him of the method I adopt in hardening small drills for tempered steel. I take a lighted candle and hold the point of the drill in the flame until it is a dull red, and then dip it into the melted tallow. Care must be taken not to bend the drill in dipping. I find this method very successful for cutting anything hard, using turpentine to the drill instead of oil. Perhaps "A Watchmaker" is not aware that as much depends upon the form of the drill as the tempering of it.

When the article is very hard, the hole should be begun with the drill, formed as in No. 1; then after it is entered the face as in No. 2, and then as in No. 3; when with a good chisel face it will cut its way beautifully.

JOHN MCKAY.

ECCENTRIC CHUCK.

Sir.—"W. G. P."—To cut the screw in the dividing wheel of an eccentric chuck:—

Divide the same with the number of teeth required; then take a small cold chisel ground to the form of the V thread of your tangent screw; then, with two or three blows of a light hammer, drive the chisel into each mark, then mill it up with a screw hob in the lathe.

WM. SMITH.

MARINE GLUE.

Sir.—In reply to "J. Bunney," I send the following:—In half gallon of mineral naphtha, dissolve two ounces India-rubber. When the rubber is dissolved add more than twice the quantity of shellac than naphtha; then put the whole in an iron vessel, apply heat, and stir till mixed. Then pour out on slab to cool, and cut in pieces. This glue is to be melted like common glue, and applied with a brush. When dry, it is perfectly insoluble, besides being elastic.

F. H. COLLINS.

If the light emitted from a heated platinum wire be examined by means of a prism, it will be found that as the heat increases in intensity, so the various colours of the spectrum are emitted until it reaches a white heat, when all the colours will be found to be correctly and simultaneously displayed.

THE mineral statistics for last year show that the quantity of coal produced from 3,268 collieries amounted to 92,787,973 tons, which is valued at the pit's mouth at £23,176,968. Of this the foreign exports were 8,500,000 tons, an increase of 500,000 tons in comparison with the returns of 1863.

THE Liverpool Corporation, under the powers of a new local act, are about to provide a series of lectures on art and science, to which the public will be admitted gratis.

WELDLESS TYRES, CIRCULAR ROLLING, AND RAILWAY WHEELS.*

In this paper an account is given of the mode of making tyre hoops for railway wheels prior to the invention of weldless tyres, and that such mode consisted in bending a straight tyre bar into a hooped form, the ends of the bar having been previously prepared if the weld to be made were any other than a "butt" weld, and then in uniting the ends together by welding in one of the methods known as the "scarf" weld, or the "double V," or the "bird's mouth," or the "single V" weld, that each one of these welds required the operation to be performed when the tyre was removed from the fire, and that they were all of them objectionable. The writer believed the butt to be the best weld of all, but that nevertheless even this best of welds was from the risk of unsoundness a source of danger. He then briefly describes the process of "blocking" the welded tyres for the purpose of stretching them to uniform sizes, and also with the view of ascertaining the soundness of the weld, and then alludes to the operation of shrinking the tyre on to the wheel centre, either preceded or not by a boring process, and then speaks of the fastening on of the tyre, and of the completion of the wheel by the turning of the exterior of that tyre.

A description follows of the mode in which in the year 1844 Mr. Bramwell proposed to make tyres without a joint weld, now known as "weldless tyres." This mode consisted in winding a long bar of iron into a helical coil of very nearly the size and shape of the required finished tyre hoop, and then in placing this coil in a circular furnace having an opening or "gash" of the form of a sector of a circle when seen on plan, such sector subtending about 60 deg. or 90 deg., and having placed within it a quick-going mechanical hammer, provided with tools of nearly the shape of the finished tyre, and adapted to operate on that portion of the hoop that lay out of the furnace and in the sector. By this means the writer proposed to weld the whole circumference of the coil by bringing welding hot portions successively out of the interior of the furnace into the sector-shaped "gash." He proposed to finish off the ring forging thus made by means of the circular or rolling machine which had been invented by Mr. Bodmer in the year 1839, by which the continuous rolling of a ring could be effected. Mr. Bodmer, he said, did not propose to make a weldless ring, but, on the contrary, intended to make that ring by welding together the ends of the bar, and that the object of his invention was to finish tyres by rolling instead of by turning them in a lathe. The writer then states that, although between the years 1844 and 1845 some few persons brought forward propositions for making weldless tyres, nothing really was done, as far as the writer knows, in the way of manufacturing; that in the latter year the writer proposed the subject to Mr. William Owen, of Rotherham, who commenced to make weldless tyres in the year 1860; that prior to this, viz., about the year 1856, the manufacture of such tyres was begun by Jackson, Patin, and Gaudet, in France; that Mr. Owen, and the limited company who have succeeded him, have carried out the making of weldless tyres to a very large extent, using machinery nearly the whole of which has been designed by the writer, and that they are now increasing their works. The writer then gives a description of the process then pursued by the Owen's Company, which consists in making a helical coil of about half the diameter, and three times the width of the intended tyre, the heating of this coil in a furnace, and then putting it into a mould on the anvil of a steam hammer, and by the action of the top tool uniting it into a block of about half the diameter, and twice the thickness of the finished tyre; the removal of this block to a circular rolling machine on Bodmer's principle, but combined with hydraulic power of such character as to be capable of rolling out the tyre to its proper decreased thickness and increased diameter.

The writer then goes on to show that not only is the manufacture of weldless hoops completed by circular rolling one that insures soundness and safety, but that also in consequence of dispensing with the "crop ends," and of passing backwards and forwards of the bar being rolled, both of which accompany, and are drawbacks to ordinary rolling; such manufacture of weldless hoops is really an economical mode, and might be advantageously employed for the manufacture of all heavy straight bars, rails, and plates. The writer then alludes to the making of steel tyres by the various processes used by Krupp, Bessemer, Vickers, and Owen, and points out how

* Read by E. J. Bramwell, C.E., before the British Institution.

beneficial the use of weldless rings would be for boiler work, as they would dispense with the longitudinal seams which are the source of weakness in boilers. He next describes the improvement in manufacturing solid wrought-iron wheel centres invented by M. Arbel, of France, and practised by the Owen's Company (Limited), which consists in putting together the various parts forming the rim, spokes, and boss, and heating the same in a furnace from which they are removed into a die, where, by the action of a powerful hammer, having, when its moving parts are fitted so as to make the centres of engine wheels, a weight of more than 25 tons, and a maximum drop of 6 feet. A common kind of wheel centre in very general use, wherein wrought spokes are combined with a cast-iron boss, is next described, and the objection to this mode pointed out; he then states the improvement of Mr. Lahousse, of Belgium, as practised by the Owen's Company, by which the advantage of a wrought boss can be obtained at a rate as economical as that of a cast-iron boss, and shows that is done by enveloping cold or moderately heated wrought-iron spokes in the highly plastic halves of a welding hot wrought boss, by which the spokes are firmly embraced and held fast.

THE SOUTH STAFFORDSHIRE AND WORCESTERSHIRE COAL-FIELDS.

The first public lecture in connection with the recent meeting of the British Association was delivered by Mr. Jukes, on the subject of the probable extent of the coal measures beneath the red rocks of the Midland Counties. Mr. Jukes, after giving a history of the South Staffordshire and Worcestershire coal-fields, and showing from the rapid consumption of fuel that new and more difficult ground would have to be opened, proceeded to notice some of the difficulties in the way of satisfactorily reaching the untouched strata. Should additional coal be found in Staffordshire and its vicinity, it would have to be sought beneath the red sandstone, which careful surveys proved to exist to a considerable extent, and the practical problem for solution was under which part of the red sandstone did coal measures, with workable coals, exist. How thick was that new red covering in those parts? and did the permian rocks also occur between the sandstone and the coal? were most important questions, and difficult to answer. The problem was one which might fairly be put before her Majesty's geological survey, under Sir R. I. Murchison, with the expectation that some approximation to its solution would be authoritatively stated. As regarded the thickness of the red sandstone, it was probable that such of the two sub-groups into which it was divisible attained a maximum thickness of 1,000 or 1,500 feet, though it was doubtful whether they ever both had that maximum at any one locality. In sinking for coal, then, anywhere in the red marl, it would be only prudent to allow 600 yards, or 1,800 feet, for the thickness of the sandstone, and three or four hundred yards additional for possible permian rock. A possible thickness, then, of 1,000 yards, would have to be passed before arriving at that point at which the occurrence of coal measures would be possible. If they did occur, a still further depth of 300, or perhaps 400 yards, might have to be reached before a good workable bed of coal could be found. At the Duke of Newcastle's pits, near Worksop, after piercing the permians they sank 1,280 feet before reaching a good workable coal. Anyone intending to try for coal beneath the red rock must be prepared to sink boldly 1,000 yards before he had a chance of meeting with the coal measure. It was quite possible that the red rock covering (taking trias and permian together) might have that thickness at any spot selected. There was then a chance, and only a chance, of the speculator finding himself in the coal measures with good beds of workable coal still beneath him. But there was only a chance of finding coal measures destitute of valuable beds, or of not finding any coal measures at all, but coming down into millstone, grit, or carboniferous limestone, or some lower palaeozoic rock, the coal measures having been removed by denudation before the red rocks were deposited. In such a hazardous speculation they could not expect private individuals to engage. The work would either have to be undertaken by a combination of proprietors, or it would have to be undertaken at the expense of the nation. Mr. Jukes declared his opinion to be, that the national importance of determining the extent and position of the coal fields beneath the red rocks of the Midland counties was so vast that the exploration must be made at the national expense, with of course every fair provision for its repayment by those most immediately benefited by it.

WINTER'S ELECTRICAL MACHINE.

In number 27, we expressed our determination to close our columns for the present to the subject of electricity, but the flood of letters which have come to hand has induced us to keep open for a week or two longer. To satisfy a crowd of correspondents, who seem altogether to have forgotten that what they have asked for has been published at length, and to enlighten several on a few new points of interest, we give an illustration and description of the machine invented by Herr Carl Winter, of Vienna. It was first introduced into this country by Dr. R. M. Ferguson, of Edinburgh, in 1857. The Doctor had seen one in Vienna and different cities in Germany before he had one made. The largest he saw was in the Vienna Polytechnic School; it had a plate 5 feet in diameter which gave off sparks 4 feet long. How-

ever, a very good size is a 2 feet plate. At first the pillars were made of glass, but Mr. Varley, of London, made his large sized one of vulcanite, and found the insulation improved. The machine is essentially a plate friction machine, and with a 2 feet plate will give 11 inch sparks. If made in the ordinary way such a machine would be considered very successful if it gave, in the most favourable circumstances, a spark of 5 or at most 6 inches. All who have had to do with electrical machines know how extremely difficult it is, even with the requisite means of drying, to keep them in a state favourable to ready action for any length of time; though Winter's machine he left in a room for months where, during that time, there has been no fire, yet by the first turn of the plate it will give sparks 10 inches long. The cause of this efficiency may principally be attributed to the rubbers he employs, the perfection of insulation, and to the contrivance for lengthening the spark. The accompanying illustration represents one of these instruments. It will be seen that the plate is fixed into an axle which revolves in two upright supports. One of these in which the shorter wooden end of the axle revolves is made of glass, and the other, in which the longer glass end of the axle revolves, is of wood. Thus the electricity formed upon the plate cannot reach the ground on either side, for on the one side the insulating glass pillar, and on the other the insulating glass axle, prevents it. The friction, as usual, is caused by pressing on the plate of glass a flat surface of leather covered with an amalgam of mercury, zinc, and tin, which is put on with the aid of a little grease. The frame standing on the low glass support to the right of the figure is the wooden rubber frame, into the notches of which fit two flat pieces of wood covered in front or on the side next the plate with leather, and a very little stuffing, and provided on the other side with springs, which, acting against the frame, keep the front surface uniformly pressing against the plate. There is only one pair of rubbers, not two, as in ordinary machines, and this enables them to be placed at a greater distance from the prime conductor of the machine.

The brass ball on the tall glass support to the left is the prime conductor. For more perfect insulation this ball is fitted on to the support by means of a trumpet-shaped opening made in it, thereby preventing the dispersion of electricity that would arise from the sharp edge of a hole exactly large enough for the rod. There are three other openings in this ball, one on each side, and one at the top. The two

small rings which are seen projecting upon the plate fit into one of these by means of a T-shaped piece of brass. They are made of wood, and have a groove cut in them on the side turned towards the plate, into which a row of fine pin points is fixed for collecting the electricity formed upon it. These points are connected with the prime conductor by means of a strip of tinfoil which lines the bottom of the groove. Two wings of oil silk, attached to the rubbers, stretch between them and these rings, so as to prevent the electricity from dispersing itself before reaching them. The opening in the top of the ball is made to receive the stalk of the wooden ring, which is seen surmounting it, and which forms the most peculiar feature of the instrument. The function performed by this remarkable appendage is to lengthen the sparks given by the machine.

WINTER'S ELECTRICAL MACHINE.

It is a wooden ring, and may be from 32 to 36 in. diameter, with a thin iron wire inside to form a core, which also passes down the wooden stalk, and is in metallic connection with the brass ball or prime conductor. This ring can be removed at pleasure; when removed, it is an ordinary plate machine of the best construction. The sparks then are straight and thick, and not more than two or three inches long; whenever the ring is put on they are at once lengthened to 10 or 12 inches. It would seem that the electricity accumulates with great intensity on the thin wire which forms the core above noted, the wooden covering preventing dispersion. Dr. Ferguson tried different rings; he had one of polished iron wire, and got 6 in. sparks; covered with gutta serena he obtained 12 in. sparks; puncturing the covering the length of spark fell to 6 in. Other kinds of rings were tried, but none proved so good as that described. This is probably owing to its semi-conducting power, or superior

elasticity, or in that it cannot be permanently punctured like gutta serena. To the left of the figure is the spark drawer, for receiving the sparks from the machine. The length of the spark is the test of the construction of a machine, and it would appear that in this respect Winter's holds first rank. Indeed, it is something quite novel in the history of electrical apparatus; concerning which, Mr. W. Hart, of No. 7, North College-street, Edinburgh, has expressed his willingness to answer correspondents by letter.

TURNED, &c., WORKS IN IVORY.

According to the nature of the work done in this useful and ornamental substance, so is the mode of polishing; and the remarks on the subject applicable to the tusks of the elephant and other animals apply

also to vegetable ivory and bone, when applied to similar uses.

Plain surfaced turned works may be left so smooth from the tool as to require no polishing, and this point is always aimed at by a good workman, who will provide himself with the sharpest of tools. In polishing very fine glass or emery paper is first used, and the work is rendered still smoother by rubbing the faces of two pieces together; next, whiting and water, as thick as cream, is applied on wash leather, linen, or cotton rag, which should, moreover, be so thin that the fingers may readily feel and avoid the edges of the work to be left keen. 3rdly. When the work hangs less to the rag than at first, it is washed with clean water on a rag, and finally, is rubbed with a clean rag with a clean dry cloth until all the moisture is absorbed, and a very minute quantity of oil or tallow is put on with a rag to give a gloss. Scarce any oil remains behind, and the apprehension that the ivory will absorb it and be thus disposed to turn yellow may be discarded; the quantity of oil used is very small, and its main object is so to lubricate the surface that the rag may not hang and so wear rings or groove marks. Putty powder is frequently used for polishing ivory work, but it is not more suited for the work than is whiting, and is more expensive.

The turned works consisting of many parts should be polished separately, as they are then more manageable, and the whiting and water have not the chance of penetrating and clogging the joinings, and so preventing their easy separation. The best workmen frequently polish screw

threads, to ensure easy movement, and to make them live longer without wearing loose. The practice is to be commended. Those turned works ornamented with the eccentric chuck, revolving cutters, &c., also require to be cut with very sharp tools, to save polishing.

Irregular surfaces are generally polished with a moderately hard nail brush, supplied with whiting and water, lightly applied in all directions, so as to penetrate every interstice; after a period the work is brushed with plain water and a clean brush to remove every trace of whiting. The ivory is dried by wiping and dabbing with a clean rag, and is afterwards allowed to dry in the air, or at a good distance from the fire. When dry, a gloss is given with a clean brush, on which a minute drop of oil is first applied.

"It is better to do too little polishing at first," says Mr. Holtzappel, "so as to need a repetition of the process, rather than, by injudicious activity,

to round and obliterate all the delicate points and edges of the works, upon the preservation of which their beauty mainly depends."

Superior flat work is accurately filed and scraped, then cleaned with fine glass paper, folded round a square stick; afterwards with whiting placed on a flat square stick used as a file. This naked polisher produces a more exact and better defined edge than when covered with cloth. Common filed and carved works are finished, first, with Trent sand and water on a flannel or brush; 2nd, scraped Flanders brick similarly applied; and 3rd, a wet rag with powdered chalk, which soon rules down smooth. Razors and knife handles are finished sometimes by shaving or scraping, or by buffing them on the wheel; some prefer the following methods:—(1.) common razor handles are first sawn out and filed, then scraped with the shaving blade: two razor handles or scales are then held at the one end in a pair of clamps in the vice, and rubbed lengthways, first with chalk and water on felt or cloth, and then with whiting and water for the finish. (2.) In the case of best razor handles, two scales are slightly rivetted together and buffed—first, on a buff wheel fed with Trent sand; next, buffed with rottenstone; and lastly, they are polished with the naked hand and rottenstone. Other workers omit the rottenstone, which requires oil, using chalk and whiting, which require only water. (3.) Umbrella and parasol handles, and many similar pieces are polished, first, with sand, and then with whiting, on cloth wheels (several circles of cloth or felt clamped between two discs of wood); the cloth projecting about an inch around the margin to make a soft elastic edge.

With these simple means is produced the beautiful polish on ivory surfaces.

CHEMICAL AND MECHANICAL OIL-TESTS.

(Concluded from page 27.)

Fish oils may also be detected by passing chlorine gas through suspected oil, whereupon a black coloration ensues. Mr. Tomlinson determines the quality of some oils by letting a drop fall from a chemically clean glass rod held just above the surface of a glass vessel containing perfectly clean and undisturbed water. The peculiar form and general appearance of the drop indicates very distinctly the nature and quality of the oil. This process enables one not only to detect common adulterations, such as of olive oil, for instance, with poppy or sesame oil, but even to distinguish the respective oleines of beef tallow and mutton tallow. Engravings of the appearance of drops of various oils, and other particulars, are to be found in the paper read by Mr. Tomlinson before the Society of Arts, and published in their Journal, Vol. XII., 1863-64, page 246.

There are several varieties of mechanical tests for lubricants. M'Naught's oil-test has had the longest reputation. This well-known contrivance consists essentially of two revolving discs, between which the lubricant is introduced. The centre of the upper disc rests upon a pivot in the centre of the lower one, the latter being driven by a cord-pulley on its spindle. The film of the oil to be tested is interposed, and, as the upper disc is carried round by reason of the tenacity of the oil on the lower revolving one, it presses, by means of a pin, upon the end of a lever in connection with a steelyard lever carrying an adjustable weight. The tenacity of the oil, or, in other words, the want of lubricating qualities, is thus indicated and measured by the weight which the pressure of the pin of the upper disc will raise on the steelyard. The oil-test of Desbordes, of Paris, is identically the same. Hirn's oil-test is also similar in principle to M'Naught's—a hollow revolving drum taking the place of the lower disc, whilst the upper one is represented by a bearing resting freely on the drum, and carrying a long steelyard, to the one end of which a scale-pan is hung, whilst to the other a weight is attached as counterbalance. The oil is introduced between the bearing and the drum by allowing the lower part of the latter to revolve in a vessel containing the lubricant, and its tenacity is measured by the weight that is required to counteract the raising of the scale-end of the steelyard, caused by the friction of the drum upon the bearing whilst revolving in the opposite direction. The heat created by the friction is estimated by one thermometer, which measures the temperature of water injected into the hollow drum, and also by another thermometer placed in a suitable part of the bearing. The speed of working is likewise determined by a little contrivance, and the combined results indicate, with considerable accuracy, the nature and value of the lubricant. The chief objection against it is the considerable oscillation of the steelyard. Waitelli's oil-

test is constructed on the same principle as Hirn's, but is so complicated as to require three or four woodcuts to describe it properly. It is used a good deal in Germany.

Sinclair's oil-test is simple and cheap. A short horizontal spindle has end journals carefully turned upon it, to run in brass bearings fixed in the tops of two brackets or pedestals. The central portion of this spindle is increased in thickness, and is turned with a spiral groove to receive a length of 3-16ths of $\frac{1}{2}$ inch gut or cord. One end of this cord is looped on a pin in the spindle, whilst to the opposite end a weight is hung. The shaft carries at one end a fly-wheel to give it impetus when in motion. The oil to be tried is laid on the two journals, the weight is wound up, and then allowed to descend freely, the cord of course falling off the pin when run off. The quality of the oil is determined by the length of time the shaft revolves, which is easily ascertained by a seconds watch. Thomas's oil-test is very much the same, a disc taking the place of the barrel of the spindle and giving sufficient impetus to enable the fly-wheel to be dispensed with.

Nasmyth's oil-test determines the quality of a lubricant by finding how long the oil takes to flow down an inclined plane. A plate of iron, six feet long, provided with a number of longitudinal grooves of equal size, is placed so that one end is an inch higher than the other. Equal samples of each of the oils to be compared are then poured simultaneously into the upper end of these grooves, and are then left to flow towards the lower end. Some oils which for the first two or three days appear to be most fluid and make the furthest progress begin to thicken, and are then passed by the better oils, some of which continue the race eight or ten days. In Mr. Nasmyth's trials, for instance, linseed oil flowed most freely for one day, but stopped within 18 inches of the top, whereas sperm oil flowed nine days to within two inches of the bottom. C.O.P.

PHOTOGRAPHY.

TRANSFERRING PHOTOGRAPHS TO METAL FOR PRINTING.—Same months since we called attention to some very promising experiments in this direction, conducted by Mr. Woodbury, of Manchester. These have resulted in a process recently patented, which is likely to assume a very important position in the arts. Mr. Fox Talbot has the merit of first pointing out the facts upon which it is based. This gentleman, to whom photographers too often forget how much they owe, discovered in connection with one of his photo-engraving processes that gelatine when dissolved in hot water, if mixed with bichromate of potash or ammonia, dried and exposed to the action of light, would become insoluble. A result due to the decomposition of the alkaline bichromate and the liberation of chromic acid. It will at once, therefore, be seen that a coat of the bichromated gelatine on a glass or metal plate placed under a negative and exposed to light, would, when subjected to the action of hot water, be dissolved away in some parts, and in other parts unaffected, thus producing a photographic positive in relief. Acting on these facts, Mr. Woodbury takes the image in relief so produced, and either by mechanical pressure with some soft metal, such as type metal, or by the usual process of electrotyping, produces an *intaglio* impression therefrom. A properly prepared ink, formed with gelatine and some black or other coloured pigment, is then passed over the plate, with which the impression is filled up even to the surface. Of course the gradations of relief in the bichromatic gelatine print, form gradations of *depth* in the metal *intaglio*, in which again the ink, being transparent, forms gradations of blackness proportioned to its varying thicknesses.

A NEW DEVELOPER.—A very valuable suggestion emanating from Mr. Carey Lea, has brought forward a new and superior developer, the best formula for which, perhaps, is one given by a clerical correspondent writing to the *British Journal of Photography*, who says:—"Dissolve ten grains of Nelson's gelatine in an ounce of Beaufoy's acetic acid (that at 10d. per lb.). Make your new developer of the strength you are accustomed to use—of course without any acid; and to each ounce of it add one drachm of the gelatinised acetic acid. You will be pleased with the result, and with its cleanliness and ease of preparation." This developer will be found to bring out the images with unusual vigour and brilliancy, and may be retained on the plate for a long time without "fogging." Where from unavoidable difficulties under-exposure has arisen, this quality alone will render it invaluable.

PROGRESS OF INVENTION.

STEREOMETAL.—This important alloy possesses some valuable properties which make it well deserving of attention. It may, in many cases, be substituted for bronze, iron, or steel, with great advantage, and is likely to prove valuable to the makers of various kinds of instruments and machinery. It is formed by fusing together from 55 to 57 per cent. copper, from 40 to 42 per cent. zinc, 1·8 per cent. iron, and from 0·15 to 0·8 per cent. tin. The colour of this compound is very similar to that of gold. The cast metal is rendered malleable and ductile by hammering or pressure, at a red heat—a higher heat would produce brittleness, and a lower would injure the texture. The tenacity of the cast metal is equal to the support of 42·29 kilogrammes the square millimetre; of the malleable, to the support of 53·99 kilos.; and of the ductile, to the support of 59·72 kilos. It takes a fine polish.

BLACK PHOSPHORUS.—Hitherto we have been accustomed to consider white as the colour of perfectly pure phosphorus, or red when the phosphorus is in the amorphous state. There is now, however, good reasons to believe that its normal colour is black. Long ago, Thenard obtained black phosphorus; but the process he used was more or less uncertain, and it was never repeated with success by other chemists. M. Blondlot has, however, discovered an infallible process for obtaining black phosphorus. He purifies phosphorus of the ordinary kind by repeated distillations in a sand-bath and in a current of hydrogen; the yellow or impure portion, which is volatile—and therefore not separable by distillation—being changed into red amorphous phosphorus, which is fixed, by exposure for several days to insolation, previous to each repetition of the process of distillation, and the product being received into distilled water, kept at 90° Cent. When the phosphorus is becoming thoroughly pure, if slowly cooled, it will on falling to 42° be a white mass, which, when, 8° or 10° are reached, suddenly changes to black. Black phosphorus becomes colourless again by fusion, but recovers its blackness if slowly—and sometimes if suddenly—cooled. It is like common phosphorus, except that it is more stable, softer, and more flexible. It becomes coated with white, in water; and with red, in the atmosphere: but a single distillation renders it, in each case, again black. Very old phosphorus—it is supposed by some kind of spontaneous purification, depending on a change in its molecular condition—is very often changed to black throughout its whole mass, except the outside, which is red.

A SIMPLE METHOD OF PRODUCING ICE ON A LARGE SCALE.—Refrigeration is now used extensively for industrial and other purposes. Solid matters dissolved in fluids are thoroughly separated from them by freezing; and the principle has been applied with great success to the obtaining of the sugar from syrups, &c. A simple and economic method of producing a freezing temperature is therefore of considerable importance. A new method of effecting this has recently been tried in Paris, with very successful results. It depends on the circulation of ether; but unlike the other processes in which this is used, it requires no pump. The amyletic ether which is employed is obtained and purified in the usual way. Its vapour is transmitted at a pressure of from five to seven atmospheres into a vessel, in which it becomes liquified. When a cock is opened for the purpose, it passes from this vessel into spiral ducts which surround the reservoir filled with the water, &c., which is to be frozen, and immersed in a solution of salt, which is not frozen even by a very low temperature. After having been vaporized in the spirals, the ether vapour passes into three large cylinders containing sulphuric acid, by which it is absorbed. A portion of the ether is always ready to be driven from the saturated solution containing it, by means of the heat which is supplied by superheated steam, into the vessel in which it is again liquified, preparatory to its being again used for the production of cold by evaporation. A machine calculated to form in this way 200 kilogrammes of ice in an hour has been constructed for the separation of the salts contained in sea-water.

A GOOD MARKING INK.—An excellent marking ink may be made by dissolving fused nitrate of silver in water, saturating the solution with ammonia, and adding pulverised gum-arabic, to prevent the writing from spreading on the linen. Before using this mixture, the place which is to be written upon is to be moistened with a solution of pyrogallie acid in alcohol and water, and then dried. The writing must be made with a quill pen; it will be of a deep black, and not removable by the method used ordinarily for washing clothes.

EMERY AND ITS PREPARATION.

(Continued from page 32.)

It will not be out of place to supplement the matter appearing in our last with a description of the invention of Mr. Henry Barclay, which consists in combining powdered emery into discs and laps of different kinds, suited for polishing, grinding, and cutting glass, enamel, metals, &c. The process of manufacture is as follows:—

Coarse emery powder is mixed with half its weight of Stourbridge loam, pulverised to a thick paste, with a little water. This is pressed into an iron mould by means of the screw press, and, after being thoroughly dried, is baked or burned in a crucible, or, otherwise, in a furnace, at a temperature considerably above red, but below full white heat. The clay serves as a bond to unite the particles in a solid "artificial emery stone," which, while it cuts well, does not readily show wear. Superfine grinding emery is formed into wheels, as is the previous kind; but the loam is only one fourth instead of one half of the proportion. The stones so made cut more smoothly, but not so quickly as the first.

When flour emery is made into artificial stones, it alone, moistened, is forced into the mould and fired. These fine wheels render the articles on which they operate exceedingly smooth: but they do not produce a high polish.

Slate, Yorkshire gritstone, crocus, &c., may be used in uniting the particles of emery as well as the loam; and thus the hardness and cut of the emery stone may be varied.

Emery-stone grinders are made with central holes, so as to admit of being attached on appropriate chucks or spindles, to the lathe; and the substance is so porous as to absorb much water, which is gradually thrown to the surface, so as to keep the edge conveniently moist—or, with excessive velocity, the water is "trundled" off as from a mop. Mr. Barclay made discs from $\frac{1}{2}$ inch to 8 or 10 inches diameter; but the difficulty increases with the size, the larger ones being liable to warp and crack during firing.

When the emery stone laps are required to have plane surfaces, angular or convex edges, &c., not readily moulded, the composition is fired at a low heat, turned in a lathe to the form required; and, firing at a nearly white heat, finishes the job.

Coarse emery stone has been tried in glass-cutting, and is stated to be able to take the place of the iron disc fed with sand used in roughing, of the Lancashire fine grit stone used in smoothing; and when of a proper consistence, cuts as quickly as the former, smoothly as the latter, and has the advantage, also, of maintaining its form. Fragments of these discs, spoiled in firing, have been successfully used in scrubbing off the rough sand of door plates, mouldings, &c., cast in brass.

Necessity compelled Mr. Barclay to take up the subject of artificial emery stone, as in his business, of making artificial teeth and gums, of a kind of hard porcelain, he found the small Yorkshire-stone grindstones wear out very rapidly, even when assisted by coarse sand and water. Some of the small artificial stones, made as above noted, have been in constant use for three or four years.

STEAM BOILER EXPLOSIONS.

At a recent meeting of the Executive Committee for Prevention of Steam Boiler Explosions, the following appeared in the Chief Engineer's report:—

"No. 29 explosion, which is the only one reported during the past two months, occurred at a marine engine and iron shipbuilder's work, at about twenty minutes before six on the morning of Monday, July 31st. Two persons were killed, and a third injured by the explosion. The boiler was not under the charge of this Association.

"I had no opportunity of making a personal investigation of this explosion, but have been favoured with a report thereon, accompanied with sketches from an engineer who examined the boiler officially at the request of the coroner, and gave evidence thereon at the inquest. From this it appears that the boiler was of plain Cornish construction, having a single flue, and being internally fired. Its length was 17 feet, its diameter in the shell 6 feet, and in the furnace tube 2 feet 10 $\frac{1}{2}$ inches, while the thickness of the plates was 7-16 of an inch, and the load on the safety valve about 55lb.

"The boiler failed from collapse of the furnace crown, which gave way at about 6 feet from the front end or furnace mouth, rending transversely in two places close to the seams of rivets, and also rending longitudinally for half the length of the furnace tube at a seam of rivets running along the crown

towards the back end of the boiler. The boiler was not removed from its seating; but from the rush of steam and water that ensued upon the collapse, the three men already referred to as injured were scalded, two of whom died several days after.

"The collapse was attributed at the inquest to overheating of the furnace crown in consequence of shortness of water, combined with an injudicious introduction of the feed water. This was admitted near to the hottest part of the fire, which was just where the collapse assumed the greatest amount of depression, and where it appears to have commenced.

"Although it is difficult to speak positively, without having made a personal examination, yet there appears ground at least to question the correctness of the above conclusion. The official investigation was not made until a fortnight after the explosion had occurred, since the poor men who died from scalding lingered for some days, and there were then no positive indications of the plates having been red hot. The furnace tube was not strengthened either with flanged seams or with T or angle iron hoops, and it is reported that the crown had been damaged through shortness of water some few months previously when two new plates were put in, and also that the furnace tube was out of shape when the explosion occurred, and had been so for some time: while to this it may be added, that it was at that part of the tube which had been repaired at which the collapse assumed the greatest amount of depression and appears to have commenced. It is thought to be quite possible, therefore, that the distorted shape of the tube, as well as its previous injury and repair, may have been the cause of the explosion rather than shortness of water. But without determining whether the explosion resulted from shortness of water, or from weakness of the furnace tube, it may be pointed out that both of these dangers might have been guarded against. Low water safety valves, which relieve the pressure of the steam on the water's falling below its proper level, are a great safeguard against explosions through overheating of furnace crowns. Many of them are attached to boilers under inspection, and work well. Also the furnace flue, even though somewhat out of shape, would not have collapsed from simple pressure had it been strengthened with encircling hoops so that the explosion might have been prevented had the boiler been better made and more liberally fitted. There should also have been a duplicate glass water gauge.

"It should not be lost sight of that this explosion occurred at a first-class engineering firm, since engineering firms—though by no means those who are first-class only—are too apt to consider themselves above the assistance of an independent system of periodical boiler inspection. The facts, however, are against them. The present explosion is a case in point. The boiler was made on the very works on which it exploded, and two men were killed by it. It is found as a rule that the old proverb that "the cobbler's wife and the blacksmith's horse go worst shod"—is generally applicable to the boilers of engineering firms, which is in some respects due perhaps to over-confidence. Some, however, take a different view, and only a short time since a well-known engineering firm, whose boilers are under our charge, wrote in acknowledgment of our visit of inspection, to state that, careful as they were with their own firemen, and in the management of their boilers, they still found that they derived assistance from our examinations, and felt pleasure in testifying to the value of an independent system of periodical boiler inspection even to engineers."

SALT water freezes at 28.3 deg.

ONLY 45 of 100 rays reach the eye after two reflections.

THE flame of oil lamps contains rays not in the solar light.

IN freezing water the crystals join at an angle of 60 deg.

To facilitate the tedious operation of shelling beans and peas, the *Scientific American* tells us that a Mr. Price has invented a machine. The details are simple enough, being merely a pair of rollers covered with india-rubber, similar to those used in wringing machines, and mounted in a wooden frame, in the same general way. These rollers are connected by gearing with a shaft and crank, so that when the same is turned the rollers will revolve also. In the bottom of the compartment, in which the rollers work, there are holes. These holes let the peas and beans fall into the drawer below. By turning the rollers, the pods are drawn in, and the compression causes them to burst open and deliver the peas on the other side in good order.

SCIENCE GOSSIP.

PROFESSOR GOEPPERT has published a book "On the Organic Nature of the Diamond." The fact that diamonds when exposed to the intense heat of the voltaic arc are turned black—converted indeed into coke—is seized upon to prove that this precious gem cannot have been produced by igneous action. Diamonds are stated by Goepfert to have often on their surface impressions of grains of sand, and sometimes of crystals showing, it is contended, that they must have been in a soft state. It is found that sometimes they enclose other crystals, germs of fungi, and occasionally fragments of vegetation of a higher order. All the facts known, according to Professor Goepfert, appear to prove that the diamond is the result of vegetable change, representing, in fact, the ultimate condition of a series of decompositions.

ARCHDEACON PRATT, of Calcutta, has republished his mathematical treatises, which we have noticed from time to time, the most important being that on the figure of the earth. Taking the law of universal gravitation as the basis, he calculated the resultant force exerted on a point by an assemblage of particles endowed with this attracting power, and held together in the form of a sphere, homogeneous or heterogeneous; next of a spheroid; then of an irregular mass consisting of layers nearly spherical, and thus more and more approximating to the case of the earth. He then calculated the figure of the earth—first, upon the hypothesis of its being a fluid mass, and then on geodetical principles; and he shows that the mass now consists of nearly spherical strata, whatever its former history may have been; that, on the fluid hypothesis, the form of its surface and of all its internal layers must be oblate spheroids; and that the plumbline must be everywhere a normal to its surface. In conclusion, he asserts that no better explanation of the various phenomena can be conceived than that which the fluid hypothesis presents.

M. TRECUL, in a recent contribution to the Academy of Sciences of Paris, describes a transformation which, if correct, will be equally interesting to the chemist and the botanist. While studying the *Lactuca altissima*, he separated, from the bark, by maceration, some beautiful green, needle-like crystals of globular and hemispherical forms, contained in the cellular laminae. On further examination he witnessed the gradual conversion of grains of chlorophyll into crystals. In the same communication he reports certain experiments for which he claims the result, "that organic matter contained in certain cellulose may, during putrefaction, be transformed into living bodies of a different nature from the generating species.

M. BORTOER has published a new method of distinguishing cotton when mixed with linen. A piece of the suspected cloth, about eight or ten centimetres long and four centimetres broad, with the edges unravelled, is plunged into an alcoholic solution of aniline red, consisting of eight grains of crystallised fuchsin and sixty grammes of alcohol. After a few moments the cloth is withdrawn from the bath, and washed till the water remains colourless. The cloth while still moist is placed in a little capsule containing ammonia, for several minutes. In a short time the cotton threads appear perfectly white, but the linen threads retain a beautiful rose colour.

At a recent meeting of the Academy of Sciences at Paris, M. Payen reported the results of his researches on the iodide of potassium, a compound now much employed in medicine, especially to counteract the injurious effects of certain businesses, such as painting and white-lead making. M. Payen shows how important it is that this compound should be free from the carbonate of potash, and not contain iodine in excess, in order that the physician may not be deceived in its action. M. Chevreul added some remarks, supporting M. Payen's views and suggesting inquiry into the purity of the medicines now employed by pharmaceutical chemists.

M. CARLEVARI, of Genoa, in a letter to the Abbe Moigno, editor of the *Compte*, says that he has totally renounced the use of carbonate of magnesia, giving the preference to the chloride of magnesium, which, when combined with small ordinary gas-flames and burnt in common air mixed with one sixth its volume of oxygen, produces the most beautiful light in the world. He states that he has constructed for the purpose lamps of a very simple principle and easy to manage, which he has applied to photography with great success.

In a paper read at the Franklin Institute, Philadelphia, by Mr. Albert Leeds, on the geography and geology of petroleum, he combats the opinion that the flow from the oil wells will eventually cease, and gives a statement of his reasons, based upon facts, for the statement that henceforth petroleum deserves to be ranked with coal and iron as a solid mining interest.

RANDOM NOTES.

In dry air at 32 deg. sound travels 1,099 feet per second, and 1 foot more for every degree of the thermometer.

A FIBRE of silk a mile long weighs but 12 grs., so that there are 583 miles of fibre in a pound avordupois.

MELTED snow produces about one-eighth of its bulk of water, hence snow 2ft. deep produces 3in. of water.

A PHIAL of water, in freezing, parts with as much atomic motion as would make an equal bulk of gold white hot.

THE river Jordan is said to discharge into the Dead Sea as many as six millions and ninety thousand tons daily.

THE amount annually realised from jet ornaments at Whithy, including their gold and silver settings, is £50,000.

THE coasts of England and Wales are officially considered as about 2,030 miles, Scotland 1,100, and Ireland as 1,300.

ACCORDING to the commonly-received chronology the discovery of the silkworm in China was made about the year 2640 B.C.

IN the arctic regions persons can converse at more than a mile distant when the thermometer is below zero, and the air calm.

OXEN require from five to six, and sheep from three to four times as long a period to add a given proportion to the weight of their bodies as pigs.

KOHOES are distinguished when the time between delivering a sound to its return is more than one-twelfth of a second, and there can be no echo in less than 47ft.

THE fall of the Ganges is four inches to the mile, and nine inches in the mile of land; of the Amazon four inches, and the land 675; and of the Nile six inches in 1,000 miles.

THE presence of one hundred-thousandth part of phosphorus may be detected in a body by Mitscherlich's process; and Dr. Herapath has found it perfectly possible to discover the ten-thousandth part of a grain of strychnia in solutions.

WHEN coal-gas is highly heated a compound called acetylene is produced. This is strongly illuminating, and forms an explosive compound with copper; thus explaining the cause of the apparently mysterious explosions of gas when passed through copper tubes.

IRON castings may be hardened, after finishing, by immersing them, when brought to a cherry red heat, in a solution composed of sulphuric and nitric acids and water.

MM. St. Clair Deville, Caron, and Troost, have succeeded in making rubies artificially. The violet red tint of these is said to be exactly like that of the most beautiful natural stones.

INDELIBLE WRITING ON ZINC.—An ink that will afford an indelible writing on zinc may be made by dissolving eight parts of gum-arabic in three hundred parts water, and adding to the solution, in fine powder, thirty parts sal-ammoniac and eight parts lampblack. A quill pen must be used with it.

MANAGEMENT OF GAS FOR ILLUMINATIONS.—The unscientific management of gas for illuminations has given rise to all the evil consequences which arise from over-crowding, since one gas-burner vitiate as much air as five human beings. When, therefore, large quantities of gas are burned, great attention should be paid to ventilation.

PLATING COPPER AND TIN.—Copper, tin, &c., may be plated, or when plated, repaired, by moistening the places which are to be covered with silver with a solution of cyanide of silver and potassium; then applying to the same places finely-powdered zinc, and rubbing them with a brush. Iron after having been covered with copper, by means of a solution of cyanide of copper and potassium, and the application of the finely-powdered zinc, may be silvered with the cyanide of silver and potassium and the zinc, as before.

CHEMICAL SCIENCE IN GERMANY.—Such is the appreciation of chemical science in Germany that, at the present time, two large chemical laboratories on the most complete scale are in course of being erected at Berlin and Bonn, at the expense of the State. They will cost, it is said, about seventy-five thousand pounds.

STRENGTHENING CAST-IRON.—Cast-iron is rendered very strong and tenacious by adding to it, in a state of fusion, from twenty to twenty-five per cent. refuse malleable iron, and stirring the mixture with a wooden rod. Throwing into this, while melted, some of a mixture which has been made by adding from twenty to twenty-five per cent. tin to cast-iron, heated until it begins to melt, affords a tenacious and compact alloy, which takes a fine polish.

ELECTRICITY, in excess or deficiency, is said to disturb the formation of crystals; and a thunderstorm has accelerated tardy crystallization.

ARTIFICIAL WHETSTONE.—A good artificial whetstone may be formed by grinding the refuse fragments of lithographic stone in a mill, thoroughly mixing the resulting fine powder with powdered emery, borax, and nitre. The mass is next formed in the shape of the intended whetstone, then subjected to strong pressure in a hydraulic press, and finally exposed to a high temperature, which imparts to it the tenacity of stone.

IMPORTANT PROPERTY OF POTATO-PEEL.—Hitherto it has been supposed that catalytic action was to be found only in certain organic substances, such as diastase, emulsiue, gluten, saliva, &c.; but it has recently been shown by Schonbein that it is to be discovered very generally in the organic kingdoms. Potato-peel, the root of the dandelion, lettuce, &c., possess it in a very considerable degree. Potato-peel, in the raw state, placed for ten or twelve hours at a temperature of between 111° and 112° Fahr. in contact with starch, changed the starch completely into sugar.

SUBSTITUTE FOR IVORY, BONE, HORN, &c.—Caoutchouc, or gutta-percha, is to be cut into small pieces, and, after having been well washed with water, is to be dissolved in chloroform, sulphuret of carbon, benzine, or turpentine. Chloroform answers best, if the product is intended to be white. The solution is to be effected in a well-closed vessel, and the mass is to be constantly shaken. A stream of chlorine gas is conducted into the solution, by means of a tube which reaches to the bottom of the vessel. As soon as the whole has assumed a uniform bright yellow colour, the transmission of the chlorine is to be discontinued, and the chlorinated product is to be transferred to another vessel, and well washed with alcohol. A solid, light, and white mass, which consists of caoutchouc, or gutta-percha, chemically changed by chlorine, is obtained. This white mass is to be swelled up by means of a little chloroform and constant agitation; and, according as it is desired to have a lighter or heavier material, or a more or less pure white tint, it is to be mixed with a greater or less amount of chalk, oyster-shell, marble, heavy spar, alumina, or sulphate of lead, in fine powder. The mixture is to be properly kneaded, and then formed into blocks, &c., of any required size in a press. This material may be obtained black, or of any colour, by adding a suitable colouring matter. The white, black, or coloured mass will answer well instead of ivory, bone, horn, ebony, &c., for buttons, handles for knives, or walking-canes, billiard balls, keys of pianofortes, &c., and is capable of being cut with a saw, &c., and turned or polished with ease.

CHEMISTRY.

An economic method of employing the magnesium light has been devised by Signor Carlevaris, of Mondovi. He stated, in a recent memoir, that when magnesium wire was ignited in atmospheric air, or pure oxygen, the most luminous effects were not manifest till a certain quantity of oxide had been formed, and was raised by the heat produced to an exceedingly high temperature. The light in this case, as in the combustion of carburetted hydrogen, as in that of hydrogen in contact with platinum, and as in the Drummond arrangement, is derived from the solid particles raised by the flame to a great heat—a heat which dissolves and volatilizes platinum, but leaves the oxide of magnesium solid, fixed, and intact. To raise this oxide to the temperature necessary to give the greatest light, it should be presented to the flame in as small a quantity and as large a volume as possible, which is done by employing a spongy oxide obtained as follows:—A piece of chloride of magnesium is exposed to the flame of the oxyhydrogen blow-pipe, in contact with a piece of carbon. The chloride of magnesium is rapidly decomposed, leaving the spongy oxide, which gives the light in question.

A new modification of gun-cotton has been prepared by M. Blondeau, and described by him in an important paper presented to the French Academy. This new kind of pyroxyline is said to possess a much higher explosive power than the ordinary kind, and, in addition to this, is unalterable, not only at the ordinary temperature, but does not decompose at 212°. To bestow these virtues upon gun-cotton, it is only necessary to take a good specimen of the usual sort, and expose it for about four hours to the action of ammoniacal vapours. The gun-cotton becomes yellow, and a compound formed with the ammonia, having no less a formula than $C^{24}H_{20}O_{20}4(NO_2)(NO_4)(NH_3)$. This body, when dried, forms a powder, having the valuable properties we have enumerated.—Vide *Comptes Rendus*, August.

THOMPSON'S PORTABLE ENGINE.

Almost every day witnesses the advent of some improvement or attempt at improvement in the application of steam power, and especially in the portable form, and the desire for simplicity and a reduction in the number of parts has led to attempts almost without number to construct an engine with a continuous rotary movement instead of a reciprocating one convertible to rotary movement by the action of a crank. It is obvious that a constant stopping and reversing must require greater weight and strength than a continuous movement in one single direction. Among the machines exhibited at the meeting of the British Association at Birmingham was a portable engine by Mr. R. W. Thompson, of Edinburgh, on the rotary principle. The boiler is vertical, having a cylinder of 3ft. in diameter by 6ft. in height, the internal fire surface consisting of a hemispherical bottom, with the heat spreading all over it by leading to a circle of vertical fire-tubes, passing through the water. To one side of this boiler is attached the engine, which shows externally as a horizontal cylinder, about 12in. in diameter by 2ft. in length, within which the pistons revolve, the entrance and exit of the steam being provided for by the action of external elliptical tooth wheels fixed on the revolving shafts, which, causing alternate faster or slower movement of the pistons past each other, opens and closes the passages. A drum-wheel on the axis of the cylinder carries a strap, which will put in motion any required machinery. The whole is supported on one pair of wheels, with a pair of shafts attached, and can be moved by one horse. The machine as shown was stated to be the equivalent of an ordinary eight-horse portable engine, and that the relative weights were, 30cwt. the rotary engine against 55cwt. on the ordinary plan, while the cost price of the former to the latter was in the same proportion. No flywheel is needed to keep up the movement, and there is an absence of all the vibrating motion induced by the reciprocation of ordinary engines. The principle is equally applicable to portable purposes or to boats or locomotive engines. The actual consumption of fuel for work done was not given to the meeting; but, assuming it to be the same per horse power, there is nothing in the wearing parts of the machine that may not easily be replaced, and at little cost. Every improvement of this kind, placing steam more and more within the reach of every one for all the common labour-saving purposes of life, is a gain to the community. It is probable that this engine, worked by a blazing fire of petroleum, will prove the best and simplest, as well as the cleanest, moving power applicable to ship's launches, which is now found to be almost a necessity of modern steamships, economizing the strength of seamen by getting rid of the labour of the oar. Getting rid of weight in this machine is a very important matter, by allowing a larger amount of fuel, as well as facilitating the hoisting in and out.

Mr. R. Williams, late agent to the Penllyn Slate and Slab Company, has had a gold watch and chain, with a purse of sovereigns, presented to him as a testimonial, on his leaving Festiniog for a new appointment at a quarry near Corris.

COMPLETION OF THE PNEUMATIC DESPATCH RAILWAY.—Last Tuesday morning a train of two trucks containing a quantity of goods was driven through the Pneumatic Despatch tubular line of railway from the central station at the Bull and Gate, Holborn, to the terminus on the premises of the London and North Western Railway at Euston.

A FEW months since we noticed the circumstance of pigs being fed on coal. It now appears as if humanity was destined to thrive upon the same kind of food. Dr. Dyes, chief physician to the Regiment of Hussars of the Royal Guard of Hanover, having observed that sea-coal given to pigs made them grow fat, conceived the idea that its therapeutic effects on man might be equally advantageous. He therefore administered some to such of his patients as complained of abdominal affections, and is said to have obtained excellent and speedy results from this treatment. The sort of coal he prescribes, is the Piesberge anthracite, which is found in large quantities near Osnabruck.

WAVY LINES ON THE PLATE.—To obviate the tendency which some collodions have to form wavy lines when the plate is coated, the editor of the *American Journal of Photography* recommends the addition of chloroform, in the proportions of ten drops to the ounce. He says it is effectual, but we cannot say why it should be so.

A meeting has been held in Fermanagh to further the improvement of the drainage and navigation of Lough Erne. The chair was taken by John Madden, Esq. Mr. Hassard produced several maps and plans of the Upper and Lower Lakes, and read a statement which proposed the lowering of the summer level of the Lower Lake 18 inches, and that of the Upper 9 inches, and leaving the rocks at Belleek as a self-acting water-weir.

ANTI-DRY ROT.—One of the best modes of preserving timber seems to be that recently invented at Antwerp. The timber is deprived of its vegetable juices and resins by steam or boiling water, after which, and while still hot, it is immersed in any cold preservative solution or dye, which it absorbs very quickly, and to such an extent as to become dense enough to sink in water. The process depends on the principle that porous bodies, when expanded by heat, absorb liquids while contracting under the influence of cold: and the injection is effected by means of it far more rapidly and more effectually than by any hitherto in use.

A GOVERNMENT PACKING UP.—The Commissioners of Public Works of Canada accepted on the 20th ult. the tender of Craig and Valliere, cabinet-makers of Quebec, to pack and transport to Ottawa the departmental and legislative effects for the sum of 15,800 dollars.

PATENT LIST.

(From the Commissioners of Patents' Journal.)
LIST OF SPECIFICATIONS, &c. PUBLISHED DURING THE WEEK ENDING 7TH OCTOBER, 1865.

- 2841. Manufacture of steel castings, T. E. Vickers—8d.
- 2842. Excluding air in treating bodily injuries, M. Henry—4d.
- 2843. Applying rolling friction to axle boxes and journals, N. Bailly, J. C. Durand, E. G. Monard, and Z. Poirier—8d.
- 2844. Storing grain, A. C. Henderson—4d.
- 2845. Moulds for casting pipes, columns, &c., G. Robinson—4d.
- 2846. Treating hensole, &c., J. J. Moutie—4d.
- 2847. Soarfs, G. C. Attree—8d.
- 2848. Looms, F. Laches—8d.
- 2849. Crinoline skirts, J. M. Smith—4d.
- 2850. Looms, J. Bullough—1s.
- 2851. Hata, C. Vero—8d.
- 2852. Fuel, A. Wall—4d.
- 2853. Manufacture of projectiles, J. P. Nolan—10d.
- 2854. Printer's ink, J. B. B. B. B.—8d.
- 2855. Breech-loading fire-arms, T. Rostell—1s. 10d.
- 2856. Manufacture of iron and steel, S. C. Keefe—4d.
- 2857. Locking the levers of railway signals and points, R. Holiday—4d.
- 2858. Composition for painting, M. Destrem—4d.
- 2859. Grinding and polishing ink blanks, &c., K. Allinson and H. Lee—1s. 6d.
- 2860. Fire saw, J. Gotthard—4d.
- 2861. Preparing jute and other fibres, F. C. Parker—4d.
- 2862. Millstones, J. Aubin—8d.
- 2863. Printing machinery, W. E. Newton—1s. 2d.
- 2864. Manufacture of soda, W. E. Newton—4d.
- 2865. Revolving shutters, H. Grafton—4d.
- 2866. Jacquard cylinders, J. Hughes—4d.
- 2867. Working and cutting wood, H. Grafton—4d.
- 2868. Signalling in railway trains, G. Score and K. W. Slavier—4d.
- 2869. Beer engines, R. G. Grimes—4d.
- 2870. Protecting articles worn on the person, J. Sheppard—4d.
- 2871. Lamps for burning hydrocarbons, T. Rowatt—10d.
- 2872. Drying moulds or packets employed in manufacturing of go leaf, &c., J. M. Johnson—4d.
- 2873. Ornamental chains, G. T. Bonafide—8d.
- 2874. Sewing and adding railway sleepers, H. Wilson—1s. 10d.
- 2875. Moulding and planing wood, H. Wilson—10d.
- 2876. Manufacturing soda and potash, A. G. Hunter—4d.

NEW WORKS PUBLISHED

BY
E. & F. N. SPON,
16, BUCKLESBURY.

Just published, 8vo. cloth, price 18s.

PRACTICAL SPECIFICATIONS OF WORKS
executed in ARCHITECTURE, CIVIL and MECHANICAL
ENGINEERING, and in ROAD-MAKING and SEWERING: to which
are added a Series of practically useful Agreements and Reports.

By JOHN BLENKARN, Civil Engineer and Architect.

London: E. & F. N. Spon, 16, Bucklebury.

Royal 8mo. roan, price 5s.

A HANDBOOK FOR ARCHITECTURAL
SURVEYORS, and Others Engaged in Building.

By JOHN THOMAS HURST, C.E.

CONTAINS.

Formulae useful in Designing Builders' Work.
Tables of the Weights of Materials used in Building.
Measurements connected with Builders' Work.
Architectural Mensuration.
Constants of Labour.
Valuation of Property.
Summary of the Practice in Dilapidations.
Scale of Professional Charges for Architects and Surveyors, with
various useful Tables and Memoranda.

London: E. & F. N. Spon, 16, Bucklebury.

Just published, elephant folio, cloth, price 25 s.

Kept also in Limp Binding at the same price (can be rolled up in a
small compass without injury to the plates).

PRACTICAL ILLUSTRATIONS OF LAND
AND MARINE ENGINEERS, showing in Detail the Modern
Improvements in High and Low Pressure, Surface Condensation,
Superheating, together with Land and Marine Boilers.

By N. P. BURGH, Engineer.

London: E. & F. N. Spon, 16, Bucklebury.

Royal 8mo. roan, 4s. 6d., post free.

RULES FOR DESIGNING, CONSTRUCTING,
AND ERECTING LAND AND MARINE ENGINES and
BOILERS.

By N. P. BURGH, Engineer.

London: E. & F. N. Spon, 16, Bucklebury.

Eighth Edition, in royal 8mo. roan, price 4s. 6d. post free.

A POCKET BOOK OF USEFUL FORMULÆ
AND MEMORANDA, for Civil and Mechanical Engineers. By
GUILDFORD L. MOLESWORTH, Memb. Inst. C.E.

London: E. & F. N. Spon, 16, Bucklebury.

Just published, on a Sheet, price 1s.

DELANY AND OKE'S WAGE TABLES for
ENGINEERS, SHIP BUILDERS, CONTRACTORS, BUILDERS,
&c., from a quarter of an hour, in regular progression, to nine hours
and three-quarters, and from one day to ten days, at 1s. to 8s. per
day.

London: E. & F. N. Spon, 16, Bucklebury.

Just published, royal 8vo., price 7s. 6d.

THE SEWING MACHINE: Its History,
Construction, and Application. Translated from the German
of Dr. HEIZBERG, by UPFIELD GREEN. Illustrated by Seven
large folding Plates.

London: E. & F. N. Spon, 16, Bucklebury.

600 pages, crown vo., price 10s. 6d.

PERPETUAL MOTION. Its History during
Three Centuries: with ample Descriptions and Illustrations.
By HENRY DIRCKX, Civil Engineer.

London: E. & F. N. Spon, 16, Bucklebury.

Royal 8vo., cloth, illustrated with 41 Plates, price 16s.

A PRACTICAL TREATISE ON THE SCIENCE
OF LAND AND ENGINEERING SURVEYING, LEVELLING,
ESTIMATING QUANTITIES, &c., with a General Description of the
several Instruments required for Surveying, Levelling, Plotting, &c.
By H. A. MERRITT.

London: E. & F. N. Spon, 16, Bucklebury.

Just published, 8mo., cloth, 6d.

ROAD LOCOMOTIVES, an Epitome of the
New Road Locomotive Acts for the use of Owners and Drivers.
with an introductory Preface, by Thomas Aveling, London.
E. & F. N. Spon, 16, Bucklebury.

Just Published, royal 4to., half-bound, Illustrated by 84 Plates of
Furnaces and Machinery, price 42 s.

THE IRON MANUFACTURE OF GREAT
BRITAIN, Theoretically and Practically Considered; including
Descriptive Details of the Ores, Fuels, and Fluxes employed; the
Preliminary Operation of Calcination; the Blast, Refining, and
Puddling Furnaces, Engines and Machinery, and the various Pro-
cesses in Union, &c. By WILLIAM TRUBAN, C.E., formerly En-
gineer at the Dewland Iron Works, under the late Sir John Guest,
Bart., subsequently at the Haverhill and Forester Works, under Mr.
Crawshaw. Third Edition revised from the Manuscript of the late Mr.
Truban. By J. Arthur Phillips, Author of "A Manual of Metallurgy,"
"Records of Mining," &c., and W. H. Dorman, C.E.

London: E. & F. N. Spon, 16, Bucklebury.

Just Published, post 8vo. cloth, 3s. 6d.

MEMOIRS OF THE DISTINGUISHED MEN OF
SCIENCE OF GREAT BRITAIN, LIVING A.D. 1807-8. By W.
WALKER, Junr., with an Introduction by Robert Hunt, F.R.S.

Second Edition, revised and enlarged.
Containing the lives of Watt, Rennie, Telford, Mylne, Jessop,
Chapman, Maudslott, the first to introduce gas into practical use;
Rumford, Huddart, Boulton, Brunel, Watson, Beaumont, Maudslott,
Dalton, Cavendish, Sir Humphry Davy, Wollaston, Hatchett, Henry,
Allan, Howard, Smith, the father of English geology; Croxson,
inventor of the spinning mule; Cartwright, Tennant, Ronalds, the
first to successfully pass an electric telegraph message through a long
distance; Charles Babbage, Trevithick, Nasmyth, Miller, of
Dewland, and Syngerton, the inventors and constructors of the
first practical Steamboat; Professor Thomson, of Glasgow; Troughton,
Donkin, Congress, Herschel, Maskelyne, Baily, Frodsham,
Lea, Playfair, Rutherford, Dollond, Brown, the Botanist; Gilbert
and Banks, the Presidents of the Royal Society at that epoch of
time; Capt. Kater, celebrated for his pendulum experiments; Dr.
Thomas Young, and Jenner, the benefactor of mankind; Jas. Ivory,
Dr. Priestly and Cavendish, the fathers of the iron trade.

London: E. & F. N. Spon, 16, Bucklebury.

JOSEPH STANLEY,

(Late Foreman at David Hart's.)
ENGINEER AND BUILDERS' PATTERN
MAKER.

33, FIELDGATE-STREET, WHITECHAPEL-ROAD, E.
Patterns designed and arranged from instruction according to
Requirement.

MODELS AND PATTERNS

for
INVENTORS, MACHINISTS, AND
ENGINEERS,

Made in all their branches by

G. TAYLOR,

140, St. John-street, West Smithfield.

NATIONAL BOILER INSURANCE

COMPANY (LIMITED),

27, LEADENHALL-STREET, LONDON.

JOHN SMITH & Co.,

ENGINEERS AND BOILER MAKERS,

Sole London Agents.

All Boilers supplied by this firm insured the First
Twelve Months Free of Charge.

T. E. TAYLOR.

MODELLER OF NEW INVENTIONS,
LATHE, TOOL MAKER,

AND GENERAL MACHINIST,

110, FETTER-LANE, FLEET-STREET, LONDON, E.C.

Patterns made to drawing.

W. SPEECHLEY,

ENGINEER, MACHINIST.

AND LATHE MAKER,

No. 118, RAILWAY ARCH, VAUXHALL-WALK, S.

JAMES LEWIS.

(Late Lewis & Son),

ENGINEER, MACHINIST, LATHE & TOOL
MAKER, and Modeller of New Inventions.

41, GREAT QUEEN-STREET, LINCOLN'S INN-FIELDS.

(Late of 5, Wych-street, Strand.)

Machinery made to Drawings or Patterns, and Worked
out to Scale.

W. & A. GLOVER,

ENGINEERS, MACHINISTS,

LATHE, AND TOOL MAKERS,

191, OLD KENT ROAD.

SMALL SCREW CUTTING, TURNING, AND PLANING.

Fifth Edition, lately published, 8vo. cloth, now reduced to 12s.

(Postage 8d.)

TREDGOLD'S PRACTICAL ESSAY ON
THE STRENGTH OF CAST IRON, Edited by EATON HOD-
KINSON: together with HODKINSON'S EXPERIMENTAL RE-
SEARCHES. With 8 plates and numerous woodcuts.

LOCKWOOD AND CO., 7, Stationers' Hall Court.

STANDARD GAUGES, Surface Plates, Straight
Edges, Scales of Length, and other Instruments of Precision, of
great accuracy and of all sizes.

H. GARRIDE, 17 Coupland-street, Oxford-street, Manchester.

SCREW CUTTER'S GUIDE,

Price 1s. 6d., or stamps.

Containing 115 Pages and nearly 2,000 Turns of Wheels, all different
threads and pitches.

Tables for Tap making for Engineers, 1 to 6 inches, Gas Taps 1/2 in. to
2 inches, Mr. Whitworth's thread and make.

A lithograph showing a new radius gear invented by the author
of this work.

May be had at James Martin, 19, Wilson-street, New Cross-road,
Deptford, Kent.

UPFIELD GREEN,
JOINERS' HALL BUILDINGS, 79, UPPER THAMES STREET, E.C.,
LITHOGRAPHER, PRINTER, ARTIST, AND DESIGNER,
 PLANS, DESIGNS, SPECIFICATIONS, AND EVERY DESCRIPTION OF ENGINEERING DRAWINGS EXECUTED WITH
 RAPIDITY AND ECONOMY.

Estimates Forwarded for All Kinds of Turf Clocks.

Estimates Forwarded for All Kinds of Turf Clocks.

GOLD FROM 5 GUINEAS.

SILVER FROM 2 GUINEAS.

C. SUFFELL, MATHEMATICAL INSTRUMENT MAKER, 11, BRIDGE-STREET, WESTMINSTER, begs to call attention to his Improved Levels and Theodolites, as manufactured for Her Majesty's Government. The pocket sets of Instruments, from 16s. to 42s.; Telescopes, 5 miles range, from 6s. 6d.; 10 miles ditto, 8s. 6d. and 10s. 6d.; Boxwood scales, engine divided, 2s. 6d.; T squares, 1s. to 5s.; Measures and Rules of all nations. Post-office orders payable at Charing Cross branch. Lists of prices forwarded on application.

TUCK'S PATENT STEAM PACKING.

TUCK'S PATENT ELASTIC PACKING AND METALLIC LININGS FOR STEAM-ENGINES, PUMPS, &c.

ADVANTAGES.—A more perfect vacuum is obtained, Friction reduced, great saving in oil and tallow, and the Packing is gradually and completely worn away without becoming hard, thus obviating the necessity of drawing the Old Packing.

J. H. TUCK & CO., 35, CANNON STREET, E.C.

VULCANISED INDIA RUBBER GOODS.

VALVES, WASHERS, ROSE, MILL BANDS, &c.

J. H. TUCK and CO., 35, CANNON STREET, E.C.

W. LANGTON'S PATENT SELF GENERATING GAS STOVE

BOILS or Frys by Methylated Spirit generated into Gas, free from smoke or smell, and is the most useful and economical invention for the purpose ever offered to the public.

Sold by all Ironmongers, and at the Manufactory.
 36, CHARLES-STREET, HATTON-GARDEN.

WRITING, Grammar, Correspondence, Short-hand, Bookkeeping, Arithmetic, Geometry, Algebra, Chemistry, Electricity, Magnetism, Practical Mechanics, and Mechanical Drawing taught by post by Wm. BROOK, Postal School, Almondsbury, Huddersfield. Lemon, 4 stamps (free).

To Electroplaters.

GAS CARBON (not compressed) Cut in Plates

or Blocks for Batteries
 Price Lists, on application with stamped envelope.
 F. HENDERSON, 3, Park-hill, Clapham, Surrey.

THE IMPROVED LEATHER DRIVING STRAPS FOR MACHINERY

are stronger for a given weight, more durable, and cost considerably less than any other kind of Driving Belt. Special Straps for Portable Engines. Price Lists free.

Turmer's Patent Strap and Hose Company.
 Manufactory, Armit Works, Greenfield, Manchester. Warehouse, 81, Mark-lane, London, E.C. Mr. H. FERRABEE, Agent.

WHEEL, RACK, AND SCREW CUTTING.
 SPUR, BEVEL, RATCHET, WORM AND INTERNAL WHEELS cut to any size or number of teeth; also racks of any length or pitch. Dividing plates drilled or lined. Screws cut to any size or pitch. J. Wilkinson, Engineer, St. George's Works, 52, St. George's-road, S. London.

"EXCELSIOR," "EXCELSIOR" Family Sewing & Embroidering Machine

WITH ALL THE LATEST IMPROVEMENTS.

IS easy to operate, simple to learn, quiet in action, and not liable to derangement. It will TUCK, HEM, FELL, GATHER, CORD, QUILT, BRAID, and sews from two ordinary reels, requires no re-winding, and the seam, if cut at every inch, will not rip. Price from 25 6s.

WHIGHT AND MANN, 142, HOLBORN BARS, LONDON.

MANUFACTORY—GIPPING WORKS, IPSWICH.

PRICE LISTS FREE.

GEORGE CUTLER, Junr., MANUFACTURING ENGINEER, LONDON GAS-HOLDER AND BOILER WORKS, 8, WHARF, WENLOCK ROAD, CITY ROAD, N., LONDON.
 Contractor for Tanks, Gas-holders, Roofs, Purifiers, and all descriptions of Gas Apparatus executed on the most reasonable terms. Steam and Range Boilers of the best material and workmanship on the shortest notice.
MAKER AND PATENTEE OF THE GAS HEATED STEAM BOILER.
 Slide and Bypass Valves for Gas or Water Works, Bolts, Rivets, Retort Screws and Doors kept in Stock. Gas Works supplied and erected complete with main and service laying.

CRICKMER'S PATENT PLASTIC METALLIC PACKING.

FURTHER REDUCTION IN PRICE ON AND AFTER OCTOBER FIRST.

PATENT WIRE GAUZE JOINT PACKING... 1s. 6d. per lb. INDIA-RUBBER CORE PACKING (HEMP)... 1s. 4d. per lb.
 CRICKMER'S PATENT PACKING... 2s. 3d. Do. Do. (COTTON)... 2s. 6d.

This Packing takes less Tallow to lubricate it than any other, and being a Pliable Metallic Surface requiring but little Pressure to keep it Steam tight, there is a great saving in friction.

PATENT TALLOW PUMPS AND LUBRICATORS.

WELL STRETCHED LEATHER MILL BANDS, HOSE PIPES, FIRE BUCKETS, VALVES, WASHERS, &c., &c.

CAUTION.—Engineers, Millwrights, and others are Cautioned against Purchasing a Spurious Metallic Packing, purporting to be Crickmer's.

THE GENUINE CAN ONLY BE OBTAINED FROM

ALEX. ROSS AND CO.

GRANGE ROAD, BERMONDSEY, or their Authorised Agents. Price Lists upon application.

No Fitter or Turner should be without a Straight-edge.

The most reliable tool of this kind, graduated to the Standard Measure of the Realm, and manufactured with MARVELLOUS ACCURACY, may be obtained of

RICHARD LLOYD,
MILL AND MACHINE IRONMONGER
 135, STEELHOUSE LANE, BIRMINGHAM.

Clubs of Workmen supplied at reduced prices. No equal tool is sold under FOUR TIMES THE PRICE.

CHANGE WHEELS FOR SCREW-CUTTING LATHES.

NOTICE TO INVENTORS.—Office for Patents, 4, Trafalgar-square, Charing-cross. Printed instructions (gratis) as to the Cost of PATENTS, for Great Britain or foreign countries. Advice and assistance in disposing of or working inventions. Branch offices and agencies in every Continental State and in America. Established 30 years. Full information as to expired or existing Patents at home or abroad. Apply personally or by letter to Messrs. PRINCE and Co., Patent Office, 4, TRAFALGAR-SQUARE, CHARING-CROSS, W.C.

TO INVENTORS.—GENERAL PATENT OFFICES.—L. de FONTAINEMOREAU, 4, South-street, Finsbury, London; 18, Rue de la Fidelité, Paris; 32, Rue des Minimes, Brussels. Provisional protection, £7; to complete patent, £20; French patent, £20 10s.; Belgium, £2 10s. Circular gratis on application.

INVENTIONS PROTECTED BY PATENT OR REGISTRATION, at fixed and most moderate charges. The Inventors' Manual free by post, or gratis on application.—Apply to Mr. BREWER (late Barlow and Co.), 89, Chancery-lane, London, W.C. Established 21 years.

INVENTORS ASSISTED

IN Securing, Carrying Out, and Disposing of their Inventions.—Apply to Messrs. B. BROWNE and CO., British and Foreign Patent Office, 49, King William-street, London-bridge.

A Pamphlet gratis, on Cost of Patents, may be had on application.

INVENTIONS secured by Patent or Registration, on moderate terms, by application to Mr. WILLIAM BROOKES (of upwards of 25 years' experience in such matters), British and Foreign Patent Agency, 62, Chancery-lane, London, W.C.

PATENTS FOR INVENTIONS.—Full instructions may be obtained by applying to Mr. W. T. RAWLEY, Office of British and Foreign Patents, 8, Small street, Bristol.

TO SECURE INVENTIONS by Patent right at home and abroad, consult Messrs. TONGUE and BIRKBECK (gratis) 34, Southampton-buildings, Chancery-lane, W.C.

IMPROVEMENTS IN ARTIFICIAL LIGHTING.

THE ADVERTISER wishes to meet with one or two capitalists to join him in the financial development of a thoroughly practical and useful light. The invention is perfect, and has been secured. The light is far superior to ordinary gas, and much cheaper. It is quite independent of coal gas, and is applicable everywhere. It may also be used in conjunction with coal gas, where the latter is laid on, greatly increasing its light and brilliancy. Address, A. B., care of E. P. H. Vaughan, Esq., Patent Agent, 54, Chancery-lane, W.C.

THE LONDON DRAWING ASSOCIATION for supplying Engineering, Mechanical, Architectural, and General Drawing, Designs, Maps, Plans, Tracings, Wood Engraving, Electrotyping, 7, Duke-street, Adelphi, London. Enclose stamp for prospectus.

NOTICE.—Removing to No. 122, from 132, LONG ACRE, LONDON, W.C.—C. SUFFELL, Manufacturer of Improved Engineering, Surveying, and Drawing Instruments for Home or Foreign service. Every instrument of the finest quality at very reduced prices. Standard Measures of all Nations. Post-free Catalogues. Forwarded to all parts on remittance or London reference.

JOHN SHEPPARD, of 10, Marsden-square, Manchester, has specially adapted himself for the supply of **ENGINE-CLEANING WASTE**, at the following prices: White at 25s per ton; grey, 25s per ton; coloured, 25s per ton. Wadding Material, for wadding manufacturers, at equally low prices, in bleached, crimson, grey, and black. Liberal terms to shippers.

THE LENOIR GAS ENGINE.—A number of these useful and economical engines to be seen in actual work in town and country. Being free from all danger, they can be used where steam power is totally inadmissible. Exhibition, and every information supplied at 40, Cranbourne-street, Leicester-square, W.C.

HOLLOWAY'S OINTMENT AND PILLS.—**HAPPY HEALTH.**—However provident, however careful man may be, he is still destined to be assailed by sickness, and it is wisdom to be provided with a remedy against such a calamity. The Ointment and Pills discovered by Professor Holloway are acknowledged by every person who has tried them to possess the highest merit in curing all outward diseases and other maladies, resulting from violence, exposure, mineral poisons, or scorbutic taints. These Pills purify and strengthen—and thus even in moderately good health occasional doses of them prove highly beneficial by their tendency to preserve the body from impurities and weaknesses, whence serious ailments frequently arise.

PATENT HOLLOW STEAM PACKING.

THE great and peculiar advantages of this packing consist in its remaining perfectly elastic, and is so constructed and applied that the pressure of the steam itself makes the joint by entering the packing from the cylinder; thus the many objections to packing previously existing are effectually removed. Vulcanised India-rubber Sheet Washers, Valves, Springs, Hose, Glazed and Solid Tubing for Gas, Spouting Tubes, Diving Dresses, Gas Bags, Air-proof Goods, or any description of India-rubber articles made to order.

Price list or circular, with full description of packing, to be had of the only Manufacturers and Patentees of Hollow Steam Packing.

FOSTER and WILLIAMS, India-rubber Works, Cowper-street, City-road.

W. JONES

DIE SINKER,

EMBOSSER AND ENVELOPE MAKER,

MACHINIST,

PRESS AND BRASS LABEL MANUFACTURER,

DRAUGHTSMAN AND ENGRAVER ON

WOOD, LITHOGRAPHER, &c.

EAST TEMPLE CHAMBERS, WHITE-

FRIARS STREET, LONDON, E.C.

THE EVAPORATER SURFACE CONDENSER (PERKINS'S PATENT).—This simple apparatus, having now been in use for some years, can be strongly recommended as very effective and economical.

A vacuum of 26 in. can be readily obtained by evaporation alone, and all the water now required for the ordinary condenser is dispensed with entirely, and pure water is returned to the boiler, thus avoiding all sediment, &c. In non-condensing engines the water is returned to the boilers at a temperature of 212 deg.; and, by the addition of a donkey air-pump, all the advantages of a condensing engine is obtained.

References and estimates given on application to the Manufacturer and Patentee, A. M. PERKINS, 6, Seaford-street, Regent's-square, London, W.C.

BOROUGH, S.E.

Lathes from 35s. upwards,

PRIZE MEDALS,

INTERNATIONAL EXHIBITION, CLASS I. AND II.

PATENT PLUMBAGO CRUCIBLES.

The Crucibles manufactured by the **PATENT PLUMBAGO CRUCIBLE COMPANY** are the only kind for which a MEDAL has been AWARDED, and are now used exclusively by the English, Australian, and Indian Mints; the French, Russian, and other Continental Mints; the Royal Armaments of Woolwich, Brest, and Toulon, &c. &c.; and have been adopted by most of the large Engineers, Brass Founders, and Refiners in this country and abroad. The great superiority of these Melting Pots consists in their capability of melting on an average Forty Pourings of the most difficult metals, and a still greater number of those of an ordinary character, some of them having actually reached the extraordinary number of 96 meltings.

They are unaffected by change of temperature, never crack, and become heated much more rapidly than any other crucibles. In consequence of their great durability the saving of waste is also very considerable.

The Company have recently introduced Crucibles especially adapted for the following purposes, viz:—**MALLEABLE IRON MELTING**, the average working of which has proved to be about SEVEN DAYS; **STEEL MELTING**, which are found to SAVE NEARLY A TON AND A HALF OF FUEL TO EVERY TON OF STEEL FUSED; and for **ZINC MELTING**, lasting much longer than the ordinary Iron pots, and saving the great loss which arises from mixture with iron.

The Patent Plumbago Crucible Company likewise manufacture and import Clay Crucibles, Muffles, Portable Furnaces, &c., Stove Backs, all descriptions of Fire Standing goods, and every requisite for the Assayer and Dentist. For Lists, Testimonials, &c., apply to **THE PATENT PLUMBAGO CRUCIBLE COMPANY, BATTERSEA WORKS, LONDON S.W.**

LLEWELLINS & JAMES,

BRASSFOUNDERS,

COPPERSMITHS, AND ENGINEERS,

BRISTOL

Sole Makers of Clements'

ECONOMIC LUBRICATOR,

FOR MARINE, LOCO, AND FIXED STEAM-ENGINES.

(As supplied to the Admiralty, and many Engineering and Steamship Companies.)

This Lubricator offers a perfect method of lubricating all the internal parts of the steam-engine, by the vaporisation of the lubricant, saving, at least, half of the oil or tallow generally used, and lessening the "wear and tear" consequent upon imperfect lubrication.

PRICES, COMPLETE, WITH GUN-METAL FITTINGS:—

2 Pints, 62s. 6d.; 3 Pints, 67s. 6d.; 4 Pints, 75s.

BRIGHT GUN-METAL BODIES, EXTRA.

As they are fixed on the steam-pipe, the diameter of this should be given; and it should also be stated whether horizontal or vertical.

BRITISH AND FOREIGN PATENTS AND THE REGISTRATION OF DESIGNS.

Mr. H. H. MURDOCH having succeeded to the business of his late Father, which has been established upwards of Thirty Years, offers his professional services to inventors. A circular, containing full information respecting the various modes of securing protection for inventions at home and abroad, may be had, Gratis, by applying (personally or by letter), at his OFFICE FOR PATENTS, 7, STAPLE INN, LONDON.

PATENTS.

ENGLISH MECHANIC:

A Record of Mechanical Invention, Scientific and Industrial Progress,
Building, Engineering, Manufactures, Arts, &c.

Vol. II.—No. 34.]

FRIDAY, OCTOBER 27, 1865.

[PRICE ONE PENNY.]

ROBINSON AND GRESHAM'S IMPROVED INJECTOR FOR STEAM BOILERS.

HITHERTO "Giffard's injector" has been constructed in various ways so as to effect an adjustment of the annular spaces for steam and water or other liquid. One method has been by moving the hollow

partition cone or nozzle between the steam and liquid, and the central spindle cone, the external hollow cone or nozzle (herein after termed the discharging cone) being fixed, and another method has been by connecting the hollow discharging cone and the hollow receiving cone or nozzle together, and

arranging them with suitable packing, so that the larger end of the discharging cone could be adjusted to and from a fixed partition cone to regulate the space for water, the steam being still adjusted by the central cone spindle. By either of these methods, internal packing has been necessary, which it is the

object of this invention to dispense with; also, to simplify construction, and render the apparatus more effective and less liable to get out of order.

The improvements consist, firstly, in arranging and combining the apparatus so that the hollow partition cone is fixed, and so that the steam is adjusted by means of the central cone spindle, as hitherto, and in arranging the discharging cone in a peculiar manner so as to be moveable without packing, independently of the receiving cone, which is fixed. By making the angles which come opposite the nozzle of the partition cone more obtuse than hitherto a shorter range is required for adjustment, and the apparatus acts perfectly, though the space between the two nozzles varies to the extent required for adjusting the space for liquid. The discharging hollow cone is made in two parts, an internal part forming the smaller, and an external the larger end of the hollow cone; the external is fixed, the internal part is moveable, and by the larger end of this part moving to and from the nozzle of the partition cone the space for liquid is adjusted.

The necessity for packing is dispensed with by arranging so that the moveable internal part of the discharging cone will extend only a little past the nozzle of the partition cone when the space for liquid is fully open, at which point the jet or current has attained a very high velocity, and when so arranged we find the passing fluid has no tendency to escape between the internal and external discharging cone, but rather to suck in air, or to draw in any fluid which may overflow from the nozzle by accident, or an imperfect adjustment of the steam and liquid. Motion is given to this moveable internal part for effecting the adjustment of the liquid to the steam by a toothed rack on its exterior, gearing a toothed pinion or segment with it, the pinion being secured on a cross shaft, which is turned by a hand wheel or by being geared with another shaft having a hand wheel upon it. Injectors constructed as above described may be arranged so as to be readily adjusted to suit a high or low pressure boiler.

The improvements consist, secondly, in arranging and combining the apparatus forming Giffard's injector, with the discharging and receiving cones each made in two parts, an internal part forming the smaller end of each cone, and an external part forming the larger end of each cone, which external parts are both fixed. The internal part of the discharging and receiving cones is arranged similar to that above described. The two internal parts are connected so as to move together, and may be considered one piece. This internal part of the discharging and receiving cones is actuated in the same manner as the internal part of the discharging cone, as described, and packing is dispensed with by arranging so that the ends of the internal part are kept opposite the rapid part of the jet or current, so explained.

In some high-pressure injectors it will be an advantage if the space between the discharging and receiving cones or nozzles can be closed after the injector has been brought into operation. This part of the invention consists in constructing injectors with the discharging cone arranged and actuated as described, the nozzle of the internal part of the discharging cone being formed to fit like a valve into the nozzle of the receiving cone, so that when the injector has been got to work the internal part of the discharging cone may be brought against the nozzle of the receiving cone, and by this means the communication with the atmosphere may be closed.

Fig. 1, is a longitudinal section; fig. 2, a cross section in the line A, B; and fig. 3, partly an outside view. The external casing (a, a¹) is formed in two parts united by flanges (a²). One part (a) of the casing is screwed and bushed to receive the central cone spindle (b), and provided with a packing gland (b¹) round the central cone spindle, and the partition cone (c), which separates the steam and liquid is screwed so as to fit exactly in the centre of the discharging cone (d), when the two parts of the casing (a, a¹) are secured together by their flanges. The external part (d) of the discharging cone is secured into the casing (a¹) so as to be steam-tight, and in this external part the internal or nozzle part (d¹) of the discharging cone is fitted so as to slide freely to and from the nozzle of the partition cone. When this internal part (d¹) of the discharging cone gives the largest annular space for liquid, its end extends but a short distance past the nozzle of the partition cone (c), and the external diameter is kept as small as possible, so as to be opposite that part of the passage where the jet or current has attained its greatest velocity. Should the external part be made much larger in diameter, so as to terminate opposite that part where the current is moving at a slow speed, there will be leakage, and internal packing would be required, which it is the object of this invention to dispense with. The internal or nozzle

part (d¹) of the discharging cone is shown detached in fig. 5. It is adjusted to regulate the water space by a crank pin (d²), which fits into a groove formed across the exterior of the nozzle, as shown in fig. 5 and fig. 2. This crank pin is made upon the end of a short stud or shaft (d³), which has a collar upon it fitting a recess in the casing, as shown. The short shaft is kept in its place by a screw gland (d⁴), between which and the collar upon the short shaft packing is placed, and by means of the screw gland sufficient friction can be put upon the short shaft to prevent it from turning too easily. The crank pin (d²) extends a little beyond the circumference of the short shaft (d³), but by forming a notch at one side of the hole in the casing for the short shaft, it can be easily passed through. The short shaft (d³) is turned by a handle (d⁵), which may be formed with a pointer (d⁶) referring to an index (d⁷) fixed upon the exterior of the casing (as shown in fig. 3), and this index may be graduated according to the minimum and maximum pressures of steam, for which the injector is intended, so that the nozzle part (d¹) when starting the injector to work may be placed as near as possible to the correct position suitable for any known pressure of steam to be used by the injector. The receiving cone or nozzle (e) is screwed into a ring (e¹), which carries the stalk of the valve (e²), and this ring screws into the casing (a¹), so that the distance between the discharging and receiving nozzles (d¹ and e) can be adjusted when the injector is applied to suit high or low pressures. An end view of the ring and valve is shown detached by fig. 4.

Figure 6, is a longitudinal section; Figure 7, a cross section on the line A, B, Figure 6; and Figure 8, partly a side view; of one modification of the improvements. The casing is made in two parts (a and a¹) connected by means of flanges (a²) and screws, one part (a) of the casing is prepared to receive the central cone spindle (b) with its stuffing box (b¹), and the partition cone (c), as shown, and the other part (a¹) is prepared to receive the external parts (d and e) of the discharging and receiving cones, and the valve (e²) fitted at the end thereof, as shown. The internal or nozzle part (d¹) of the discharging cone (d) is arranged and fitted same as that already described, but is continued and connected with the internal or nozzle part (e¹) of the receiving cone, which slides to and fro freely, and is without packing. The internal nozzle (e¹) of the receiving cone (e) terminates where the jet or current has not materially diminished in velocity, so that there is no pressure of fluid tending to escape between the surfaces of the internal and external receiving cones or nozzles. The internal nozzle (d¹ and e¹) of the cones may be formed in two pieces, as in Figure 6, or in one piece, as in Figure 9, a longitudinal section, and Figure 10, a cross section at a, D, Figure 9. The discharging and receiving nozzles are made at their terminations of the same form and with the same space between them as in injectors with these parts fixed, the metal being shown cut away, to allow for overflow, and for the escape of fluid when starting the injector. The internal nozzles (d¹ and e¹) are cylindrical upon their exterior, and have a toothed rack formed thereon, as shown, into which a pinion (d²) gears upon a short shaft (d³), shown best in Figure 7. This shaft (d³) is inserted through a hole in the casing (a¹), which is closed by packing and a screw gland (d⁴), as shown. Upon the exterior end of the shaft a hand wheel (d⁵) is placed, which is graduated upon its edge, so that it may be set to regulate the water space to any known pressure of the steam, by bringing a point upon the index corresponding to the known pressure opposite a pointer (d⁶) fixed in the side of the casing, as shown in Figure 8.

Figure 11, is a longitudinal section; Figure 12, a cross section on the line A, B, Figure 11, which show an injector according to the second part of the invention, and similar to that shown by Figures 6, 7, 8, except that the external parts of the cones (d and e) form part of the body or casing of the injector; in other respects the injector is constructed in the same manner as that shown by Figures 6, 7, 8, except that part (a) containing the central cone spindle (b), and partition cone (c) is screwed into that part (a¹) containing the discharging and receiving cones and valve.

Figures 13, 14, 15, are outside views, partly in section, showing various methods for giving the movements for adjusting the position of the internal nozzles of the discharging and receiving cones.

In Figure 13, the worm (d¹) upon the shaft (d²) gears with the pinion (d³) that engages with the toothed rack upon the nozzle part (d⁴). It is arranged with a screw gland stuffing box (d⁵), as shown, the part (a⁴) forming the bearing and the stuffing box, and carrying the axis (d³) of the pinion (d⁴) being secured to the side of the casing (a¹) by screws.

The injector shown by Figure 14 is somewhat similar to that shown by Figure 13, the worm being enlarged in diameter, so as to gear directly with the teeth upon the nozzle (d¹), which is prevented from turning by a screw (g), the head of which moves up and down in a slot in a projection from the external discharging cone. The worm (d¹) is inserted through a slot in the casing (a¹), and is covered by a cap (a²) secured by screws.

Figure 15 shows an arrangement somewhat similar to Figure 14, except that in place of the worm (d¹) a toothed pinion (d²) is fixed, which gears with a pinion (e) fixed upon the internal nozzle (d¹), to which it gives rotating motion, the internal discharging nozzle (d¹) being made to screw into the external discharging cone (d). In each of the injectors, f represents the inlet for steam; g, that for water or liquid; and h, the overflow orifice.

Figure 16 shows the manner in which the third part of the invention is carried into effect. The nozzles (d¹ and e) are formed as shown, and ground to fit like a valve. When the arrangement is applied to injectors where the partition cones is adjustable to regulate the water space in the ordinary manner, the moveable nozzle need not extend so close to the nozzle of the partition cone as to effect the adjustment of the water space.

The inventors reside in Manchester, Mr. Robinson being connected with the Atlas Works.

PHARAOH'S SERPENT.

The following account of a curious experiment is contributed to the *Pharmaceutical Journal* by Mr. C. H. Wood:—"A very curious toy is now being sold in Paris, under the name of Pharaoh's Serpent. As this toy really constitutes an interesting chemical experiment, perhaps an account of it may prove interesting to your readers. It consists of a little cone of tinfoil, containing a white powder, about an inch in height, and resembling a pastille. This cone is to be lighted at its apex, when there immediately begins issuing from it a thick, serpent-like coil, which continues twisting and increasing in length to an almost incredible extent. The quantity of matter thus produced is truly marvellous, especially as the coil which so exudes is solid, and may be handled, although, of course, it is extremely light and somewhat fragile. Having a little of the white powder, with which the cones are filled, placed at my disposal by a friend, I submitted it to analysis, and found it to consist of sulphocyanide of mercury. This salt, when heated to a temperature below redness, undergoes decomposition, swelling or growing in size in a most remarkable manner, and producing a mixture of mellon (a compound of carbon and nitrogen), with a little sulphide of mercury. The resulting mass often assumes a most fantastic shape, and is sufficiently coherent to retain its form; it presents a yellow colour on the exterior, but is black within. The 'serpent' shape, of course, results from the salt being burnt in a cone of tinfoil. Both the mercurous and mercuric sulphocyanides decompose in the same manner; but the mercuric salt, containing more sulphocyanogen, seems capable of furnishing a larger quantity of mellon, and is the one used in the French serpents. A solution of permanganate of mercury is readily precipitated by sulphocyanide of ammonium, and the mercuric sulphocyanide may be easily so prepared. It is best to use the mercurial solution as strong as possible, and to keep it in excess throughout the precipitation. Solution of perchloride of mercury is not so easily precipitated as the permanganate, probably owing to the solubility of the mercuric sulphocyanide in the chlorides. Perhaps I may be excused for adding that sulphocyanide of ammonium, suitable for the above purpose, may be very easily and economically prepared as follows:—One volume of bisulphide of carbon, four volumes of liq. ammon. fort., and four volumes of methylated spirit are put into a large bottle, and the mixture frequently shaken. In the course of one or two hours, the sulphide of carbon will have entirely dissolved in the ammoniacal liquid, forming a deep red solution. When this result is attained, the liquid is boiled until the red colour disappears, and is replaced by light yellow. The solution is then evaporated at a very gentle heat (about 80° or 90° F.) until it crystallises, or just to dryness. The product is sulphocyanide of ammonium, sufficiently pure for the above purpose. One recrystallisation from alcohol will render it quite white. One ounce of bisulphide of carbon yields by this process one ounce of sulphocyanide of ammonium."

A Convex lens burns at 25ft. under the surface of the sea in a diving bell.

The first known use of the rail in railways is due to Beaumont, in the year 1690.

ANSWERS TO CORRESPONDENTS.

A. O. R.—Perhaps the following will suit your purpose. Stirling's and Ericsson's calorific, or hot-air engines are much used in the United States, and the action may be briefly described thus:—The chamber in the calorific engine, through which the hot air passes, is filled with fine wirenetting, placed side by side, to the thickness of twenty inches. On leaving the cylinder, the air, after doing its duty on the piston, is made to pass outwards through this chamber. In its passage, a quantity of its heat is abstracted by the metal network, and given up to the returning air, which passes inwards through the same chamber. The returning air, with a slight accession of heat from the furnace, produces another effective stroke of the piston—thus fuel is saved. In the ship *Ericsson* the engine consisted of two pairs of cylinders, connected in their action, but not placed side by side. Each pair was composed of two cylinders—the lower one (the larger) being called the working cylinder, the upper the supply cylinder. The diameter of the working cylinders was 163 inches, that of the supply 137 inches each. This enormous bore was found insufficient for the work. We believe several are at work in the north of Scotland, the chambers being of very thick cast-iron.

JAMES MASSY.—On tinfoil properly disposed on a perfectly flat surface, pour mercury, which gently rub in with a hare's foot. It soon unites with the tin, and "quicksens." Your plate of glass should then be cautiously slid on the tinfoil, so as to slide off the superabundant mercury. Then place weights on the glass, which will quickly adhere to the tinfoil. The glass should be very clean—dirt prevents adhesion. (2.) The surface to be gilt must be carefully covered with a strong animal size; when dry repeat with a sufficient number of layers of the same size mixed with washed chalk. When this is dry, a thickish layer must be added, composed of size and Armenian bole, or yellow oxide of lead. While this is yet moist, lay on the gold leaf, which will adhere on being pressed with the cotton ball; and, before the size is perfectly dry, burnish with an agate or dog's tooth fixed in a handle.

OLD CHARLIE.—Thanks—see the "Queries." We will not forget your suggestion.

R. B. (C. Ct.).—You will find a little "smeltery" described in our fortnight back, with a small illustration. If that won't suit, write again.

H. HARDINGE.—With a flint stone, then on a willow wheel, fed with pumice-stone.

W. H. H.—Fine emery paper, with oil. For cylindrical surfaces the paper is wrapped around a parallel piece of stick. Additional lustre is given with woollen cloth, oil, and rottenstone.

W. B. (Newcastle-on-Tyne).—The price charged for the printed specification, which will be sent to you by Mr. B. Woodcroft, from the office of the Commissioners of Patents, Southampton-buildings, on receipt of postage stamps. Over 5s. by money order.

JAMES WALLACE.—We made a memorandum of your wants, but have not yet laid hold of the article.

W. MECHANICAL.—If you inquire where you saw the cooking apparatus they will tell you where the article is made; or may be able to get you one. If not, write again.

T. R. WISTON.—They have no cause for complaint, as you say; but there is a great demand for the article. The article you note is finished. Your queries in another place.

AMATEUR PAINTER.—See letter in another column.

J. G.—By means of Tyler's force-pump, sometimes. If you require one, send to him at Newgate Market, and he'll return you a catalogue.

W. TAYLOR.—There is the "Wanzer" Machine Company (Limited) at 4, Cheapside.

T. G. MASON.—This query has been answered once or twice, we think, already in this place. We insert your query in another place, however.

HABITUALS.—If you look at the advertisement columns you will find your wants supplied. The parties generally keep small models on sale. You might also send to Mr. West, 92, Fleet-street.

ONE WHO BELIEVES HIS LIGHT, &c.—See Mr. Smith's letter in another column, and endeavour to see the engine. If you cannot, we'll insert your letter.

PLUMBERS.—We will endeavour to do so. You have no conception how difficult it is to get at it.

E. G. O. (East Dereham).—We think some knowledge of drawing and mechanics, and of the lathe, is considered of value; but we think, if you mean trying to get in, that it would pay you to visit the town, and make acquaintance with two or three of the men.

BRASSY.—Will endeavour shortly to meet your wishes.

CONSTANT READER (Dundee).—Your query respecting the chuck inserted elsewhere. Concerning the books, apply to Mr. Alvey, Swedenborg Society Publishing House, Bloomsbury.

H. H. H.—If you acquire the best, send to Holtzapffel, in Long-acre. If second hand, advertise. Prices vary.

W. BROOKS.—Send to Spon, Bickersbury, for their catalogue.

CIVA.—Will have seen ere this that the promise has been fulfilled. For the price of Mr. Muir's lathe, send to him, at 10, John-street, Adelphi.

J. NASH.—Read up the list in a recent number, and send to Spon's, Bickersbury, for a catalogue, and to Weale, Holborn.

J. L. (Constant Reader).—Will endeavour to supply your wants.

R. TRAYOR.—The index and cases are to be had at the office. You don't require much, certainly; were all our correspondents to want half as much, we should require—well, £20,000 a year to pay for it. What we can give we will.

. We have to ask our correspondents to sign their communications that they may be able to recognise the

answer. "A Subscriber" is no signature—we have them by the thousand; the same with "Well-Wisher," &c. If they don't like to see their own names paraded, use those of an ancient or any other man.

Several letters remain over till next week for answer. Letters applying for information to be furnished by post cannot be attended to.

Correspondents are requested to keep copies of their drawings and manuscripts, as the Editor cannot undertake to return such as may be rejected.

NOTICE TO ADVERTISERS.

ADVERTISERS in this journal are respectfully informed that the Collector from the office, 162, Fleet-street, will call upon them for a settlement of the amounts due for the insertion of advertisements. The Collector will in every instance hand in a printed receipt for the sum paid to him. Advertisers are particularly cautioned against paying money without receiving the printed receipt.

LAND AND BUILDING SOCIETIES.

A VERY interesting series of papers was read in
the Economy and Trade department by the
Social Science Congress, on the subject of our
caption; and we have to regret that the space at
our command will not permit us to do more than
give a short digest of each of three. The first was
by F. Biggs, Esq., F.S.S., and directed attention to
one of the greatest evils in the production of dis-
ease, poverty, and pauperism—viz., the state of the
dwellings of the labouring classes, and the insuf-
ficiency of home accommodation. The house had
very much to do with the manners, the habits, and

morals of the people; where the decencies of life
could not be preserved the moralities were impos-
sible. The evil of overcrowding in dwellings was
great in large towns, and had at last extended to the
villages and hamlets, and through the deficiency of
home accommodation it existed throughout the land.
He described at length the origin and history of
building societies, and of freehold land societies,
which he warmly advocated as the means of remedy-
ing the evils of overcrowding. The benefits they
conferred upon a working man were these—they
gave him higher interest than a savings bank would,
with equally good security, if he were careful in
his selection; he had all the advantages that the
merchant or trader had from a bank, and he was
able at any time to employ his deposits in the pur-
chase of a piece of land. He objected to the
monopoly which existed to so great an extent
through the land, of the country being held princi-
pally by the wealthy, which interfered with the
proper enlargement of our towns. He suggested
that a sort of Permissive Act should be passed by
which any municipality or local authority could take
land for extension of buildings or for new buildings
anywhere within the jurisdiction of any local acts
which empowered them to pave, light, or drain. He
further recommended that an easy and economic
mode of transfer should be introduced to supersede
the present cumbrous, tedious, and expensive mode
of conveyance—such a system as would render the
transfer of land as easy as the transfer of railway
shares.

Mr. S. B. Anty's paper next claims attention,
and in it he set forth the various advantages accru-
ing to members of such societies, thus: The politician
saw in them the power of increasing the number of
electors by acquiring, through the medium of these
societies, a small freehold or adequate leasehold prop-
erty. Unquestionably this was a noble object to
be attained, and gave a standing in society, and en-
abled them, though only a small unit of the great
social family, to raise their voice and support in the
election of those best qualified to direct the affairs
of the nation, and produce contentment and happi-
ness to its entire population. The essayist having
alluded to the advantages conferred upon the work-
ing classes by inspiring them with habits of thrift
remarked that the industrious were actuated by a
variety of motives in joining those societies. There
were some who cared nothing for political franchise,
but who desired social position. They observed the
advantages accruing from the possession of a little
capital, and although thirteen years might seem a
long time over which to be paying money, they
knew that if adverse circumstances overtook them
they could withdraw their money before the expira-
tion of the time. Though the principles of working
these societies were well known, it behoved the
societies to have men of experience as managers—
men understanding the science of accounts. Mr.
Anty detailed the mode in which the operations of
these societies was most successfully conducted;
and when such was the case the result was a great
pecuniary benefit to investors.

Mr. H. W. Ibbotson, Sheffield, spoke on the benefit
of building societies in general, with some sugges-
tions on the desirability of amending the law re-
specting them. Having sketched the history of these
societies and their present position, Mr.
Ibbotson selected a few of the most general benefits
accruing from them, referred in detail to their prac-
tical operation, and lastly offered suggestions on the
amendment of the law respecting them. Upwards of
2,000 societies were registered under the 6th and 7th
Wm. IV., cap. 32, up to 1850, and the societies had
since then still greatly increased. The advantages
of the societies were these:—Houses might be pur-
chased by a slight increase of payment (by small
monthly instalments) on what would be demanded for
the annual rent, and premiums or fees for apprenticeship,
marriage endowments, and provisions for old
age or for any other object whatever might be
secured by the same medium. Such societies had
tended in a remarkable degree to foster the habit of
economy and carefulness, and they had extended the
system of co-operation with the greatest advantages
to the working classes. Mr. Ibbotson next spoke of
the facilities and advantages for lending and borrow-
ing in connection with the societies, and then sug-
gested the following amendments in the law: It
would be advantageous, he thought, to repeal the
clause of the Act which limited the amount of each
share in building societies to £150, as it did no good,
but on the contrary hampered the society in its
operations; he also suggested the repeal of the
clause providing that no member withdrawing his
share before the termination of the period originally
prescribed, should be permitted to take any profits
accruing on such shares. He thought the exemp-

tion of certain legal documents from duty on such societies was not so comprehensive as it might be, and suggested that it ought to be complete, and to be applied to every description of document; he advocated the desirability of giving the directors of societies power to take personal security. He contended that the societies ought to have full power to raise loans without evading the Act (as they were compelled to do) by issuing certificates of paid-up shares; and finally, he suggested, as to the redemption of mortgages, that the precise mode in which amounts to be charged to a borrower on redemption should be calculated, and thus prevent the possibility of any future litigation on the subject.

BIRTH AND GROWTH OF THE IRON TRADE.

By JAMES ROBERTSON, Esq.

HISTORY is the portraiture of the past. It is a compound of philosophy and poetry; the philosophy affords us sound advice and lessons of wisdom, deduced from the experience of our predecessors, and confirmed by the transactions of bygone times. The poetry of history leads the imagination to realise a past state of affairs, and particularly pictures forth the life and manners of those who have transmitted the discoveries of civilization, whose names are hallowed in the arts and sciences as benefactors of their race. The historian of a kingdom such as this has a great task before him, a subject with many ramifications, embracing varied and conflicting interests, and demanding that each individual branch of manufacture should have a distinctive individuality, showing how order arose out of chaos, showing how our mechanical power and commercial industry arose, showing how the iron arose from a few hearths in remote and solitary forests to an importance truly wonderful from their colossal proportions, and to which the past history of ancient or modern times can find no parallel. I shall restrict myself to the commercial importance of the iron trade and its gradual and vast development, knowing that with a practical people like ourselves scientific discoveries, which have no real or commercial value, are seldom popular, and that the commercial value which the skill of the engineer has given to the iron trade has placed it in its present prominent position.

Manifold are the uses to which this metal has been applied—the ploughshare and the sword, the graceful needle and the ponderous anchor, the medicine of the physician administered to cure, and the deadly bal of—

"The immortal engines."

Whose rude throats the mortal Jove's dread clamour counterfeit."

owe alike their origin to iron dug from "the bowels of the harmless earth." In the form of steel it has now become, in the form of crinoline, an important element in female dress, and in Berlin it has been manufactured into trinkets, earrings, and ornaments, the price of some of which reach the astounding figure of £2,700 per cwt.

Iron must have slumbered in the earth long before the creation of man, yet if we go to Holy Writ we find that not many generations had passed away ere Tubal Cain became an artificer in brass and iron. Gold, silver, and copper are found in their perfect state, so that it required less cunning to discover these metals; still, the hidden wealth of the ironstone must have been early found out, since so soon after man's creation we have evidence of its existence as a metal. How it was discovered we have no evidence to show. Whether by revelation or science we can only conjecture; but science itself is a revelation. It is the sounding of the hidden secrets of Nature; it is the investigation by the inquisitive spirit of man of those immutable laws by which this globe is governed, and as man transmitted to his posterity his discoveries in art and science, posterity perpetuated the discoveries, whilst the means by which those discoveries were made were irretrievably lost. We find from the Sacred Volume that 1500 years before the Christian era Og, king of Bashan, had a bedstead of iron, proving that iron had, at that early period, been applied to domestic purposes. Goliath, the giant of Gath, had a spear-head of iron (B.C. 1044). There is also defensive armour spoken of about the same period, and Job says, "Oh! that my words were written with an iron pen, and cut in the rock, that they might endure for ever." Herodotus speaks of men skilled in science, brought into Greece by Cadmus (B.C. 1500), by whose abilities gold was discovered; they made arms and edge tools, and great fleets were built, which gave to Greece the dominion of the sea. The earliest writers on the manufacture of iron are Diodorus Siculus, and Pliny the elder.

(To be continued.)

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents.]

BOOKS ON TURNING, &c.

Sir,—I copy for I. H. the title page of 26 in list. The art of double-counting on the lathe, by Capt. James Ash, London, L. Booth, 207, Regent-street; and sold by Holtzappel and Co., 64, Charing-cross, 1857. I obtained mine second-hand price 10s.

Bergeron, 11 in list, Messrs. Hachette, King William-street, Strand, would no doubt obtain for J. F. It was 30 francs, say 50s., in 1820, about 45s. in 1860, and is perhaps not obtainable by this time. Valicourt is fully equal to it, price 12s or 14s. English Indian ink will not have one of the essentials of the genuine. Five or six drops of hydrochloric acid and two of spirits of wine to an ounce of water, will stop the genuine from working off in "shading up."

H. C. can never have seen a cast-steel tool exposed to nearly melting heat and turn out fit for use; at about "cherry" heat is the right degree to work at, certainly never above red-hot.

P.S. In "lathe centres" one mans 45° is the other's 90°.

Sir,—In No. 26 of THE ENGLISH MECHANIC for September 22nd, you answer J. Watson (Doncaster) by referring him to a book on "Parlour Magic," published by Becton. May I ask the exact title and price of this work? I can find nothing like it in Becton's Catalogue, or rather advertised list.

Forest Lodge, Maresfield, Uckfield.

Sir,—I have only just noticed the reply of "Mephistopheles" to "E. McDurk" (No. 26), wherein he states, that "no clock will strike the same hour twice." This is incorrect. I have one by Robbin, of Hatton-garden, which will not only strike the same hour twice consecutively, but as many times as you please. In fact, by reason of its peculiar construction, it cannot strike wrong. W. J. F.

VELOCIPEDES.

The various inquirers on this subject will, if possible, be answered in our next.

THE BELLEROPHON.

Sir,—In answer to your correspondent W. G. W. in No. 29, in reference to the overrunning of the screw in the ship Bellerophon, I beg to submit my theory of the matter. The ship Bellerophon is fitted with a four-bladed screw. The blades when viewed in a line with the shaft will show that the water from the front or cutting blade is thrown back to the other blade, which forms a dam for the water, and the screw being propelled at a greater speed than the water can free itself, it causes a round column of water to hold in between the blades of the screw, which immediately checks the speed of the engines; but the screw having previously gripped the water, a speed is given to the ship, and being heavily plated is not easily stopped, and therefore overruns the revolutions of the screw; but immediately the vessel drops its speed the water leaves the confined parts of the screw, and the screw resumes its speed again to be pulled up in a like manner when the blade becomes waterlogged. I feel thoroughly convinced that if the screw had been run at a much less speed the vessel would have travelled quite as fast, and without overrunning its screw, as the water would have had time to leave the inner circle or confined parts of the screw. Now this I know from experience, having tried six, five, four, three, and two bladed screws, but none supersede the three bladed screw placed on an angle of forty-five.

I have a working model seven feet long, fitted up with steam power, and can prove the truth of my assertion at any time.

E. E. COLLEY, Engineer.

1, Mansion-villa's, Mansion-street, Camberwell-road.

THE AMERICAN STREET RAILWAY SCHEME.

Sir,—I can scarcely believe that the New Yorkers will care to avail themselves much of the ingenious elevated railway, invented by Mr. P. Andrews, and described in THE ENGLISH MECHANIC; albeit, the inventor has kept three things constantly in view. It appears to me that the safety of both those who travel in the cars and under them has been constantly excluded from view.

An upright revolving shaft is a dangerous thing, even when in a mill among mechanics. How much more so when projecting from the footpath of a crowded thoroughfare? For the inventor's special advantage I will suggest carrying this shaft up through the inside of the supporting pillar; it would then be out of sight, and prevented alike from doing damage or being damaged itself. Even then, however, I am afraid the item "compensation" for accidents would soon swallow up a company's capital. My card being enclosed, I here subscribe myself

W. H. N.

Chard, Oct. 17th, 1865.

OUR SUBSCRIBERS' NOTES AND QUERIES.

SUBSTITUTE FOR SILVER.—What is a good substitute for the silver parts of graduated instruments? It should be white, not easily tarnished, not easily bruised, and soft enough to engrave upon, not expensive, and to melt at such a temperature that an amateur can work at.—OLD CHARLIE. [Try 90 tin, 7 antimony.]

AQUARIUM FOUNTAIN.—What is the simplest? How made.—W. BROWN.

ELECTRIC CLOCK.—In p. 244 is an illustration of an electro-magnetic clock: of what is the magnet M composed? G. PHILLIPS.

ASSAYING.—How are iron ores and galena assayed?—R. W. WESTON.

MOULDS.—The best way to make elastic moulds for under-cast work in plaster casting; also, what is the white hard varnish for plaster casts?—AMATEUR CASTERS.

SAFETY VALVE.—What is the method of ascertaining the pressure of steam a boiler can bear by the safety valve?—T. G. MAUGH.

WATERPROOFING.—Can anyone give me a recipe for waterproofing umbrellas without taking away their liveness?—CHIPS.

TELESCOPE.—The cost of a telescope object glass, 12in. in diameter, 12ft focal length, also that of the small tube with the eye glasses fitted complete; the best place to get them, and any information to assist an amateur to get one up cheaply.—SATELLITE.

HORSE-SHOE MAGNET.—What is the size of the run, and the kind and number of wire for a horse-shoe electro-magnet to lift 50lbs. or more, and the size and kind of battery required?—W. C. H.

PLATING.—What is the best way to silver-plate small things in jewellery, by simple immersion or otherwise, to stand burnishing and the colour?—G. S. L.

SOLDERING.—How can I solder very small things in jewellery, without fire? Is there not a chemical process in Birmingham?—GEO. SMITH.

TORTOISE-SHELL.—How is tortoise shell made to join without putting on a plate or rivetting?—W. H. C.

STEEL WIRE GAUGE.—Will any reader favour me with a table of the gauges of steel wire, with the diameter?—R. T. S.

CHUCK.—Wanted, a description of a chuck to hold brass rod for turning in a hand lathe.—R. T. S.

WELL BORING.—As I am going shortly to New Zealand I shall be obliged to anyone who can tell me how a tube can be driven to 20 or 30 feet, and if any and what tools are used.—J. W.

DISSECTING MICROSCOPE.—What is the price of, and where can I obtain, a Collins' dissecting microscope?—J. WHITEHEAD.

OVAL CHUCK.—I shall be obliged to your volunteer correspondent for his description of the oval chuck.—ECONOMIC.

MICROSCOPE.—How can I convert a magic lantern into an opaque microscope, such as exhibited at the Polytechnic?—J. W.

DEPOSITING.—Why is it I cannot get a good electrotype deposit—it being a brown speckled mass, instead of metallic copper? Can iron be deposited, and by what method?—J. W.

SLIDE RULE.—I have bought one, and don't know how to use it. Will anyone tell me how?—YOUNG MECHANIC.

UTILISING WASTE.—To what purpose can I put cotton waste used to clean machinery with; also, old vulcanized india-rubber steam joints, and india rubber that has been used in muriatic acid?—WOPER.

SHAWT GUTTA PERCHA.—Where can I procure really good sheet gutta percha, that will not rot readily.—YOUNG, JR.

WIND ENGINES.—Wanted, details of construction of the small wind engines used for driving chaff cutters and other small machines?—VANT.

PADDLE WHEELS.—What advantage is there in splitting the floats of a paddle wheel in two, and putting one half on each side of the arm, and the disadvantage, if any?—WM. SWINBURN.

OPALESCEENCE.—Will any one inform me the manner in which opalescence or iridescence is produced, as used in ornamenting surfaces.—FLANDERS OWNS.

STANDARD BAROMETER.—Wanted, the relative proportions between the bore of the tube and the cistern of a standard barometer—say, the tube being 3in., what is the area of the cistern. T. G. MALL.

SPEED OF ROLLERS.

Sir,—Which is the best proportion of speed for the rollers of frames used in cotton spinning. Some makers run the Back roller the same speed as the middle, while others have a draft of one into two, or more. What is the best proportion to run the middle roller, when, for instance, the back goes one, and the front six. CORROS.

STRAIGHTENING WIRE.

Sir,—I have straightened wire by boring a hole in a small log, looping the end to a bar, attaching a horse thereto, and so pulling it through. R. MITCHELL.

[Another method is to place pins on a board, thus:—

and pulling the wire through. According to the curl, so are the number of points and their closeness.]

SMALL CASTINGS.

Sir,—I am much obliged to Mr. McDurk for his description of a small furnace, and I beg to ask him to describe a crucible suitable for it—if I can make them, or where I can get them—price, time of wear, &c., &c.

AMATEUR MECHANIC.

TO HARDEN STEEL.

Sir,—In answer to M. C. B., he can harden steel by heating it in melted lead, and quench in oil. To temper, first polish or scrape it white; then hold it over the gas till it is let down low enough. W. H. E.

Sir,—A shoemaker's bench can be obtained at Mr. J. Sparkes Hall's, 308, 310, Regent-street, W.; and shoemaker's sewing machines at St. George Machine-works, St. George's-road, S. Prices, £9 and £10 each. B. M. T.

PAPER BAG MACHINERY.

Sir,—In answer to the query of J. H. B., under head of Paper Bag Machinery, call at the address below, where a new and simple machine for the above purpose has just been patented, and the machines will shortly be in the market. B. BROWN & CO.

Patent Office, 49, King William-street, E.C.

ATLANTIC CABLE.

Sir,—Four correspondent Edmund Dear, in No. 29 proposes to fill his buoy for under-running the Atlantic Cable with compressed air, evidently with the idea of giving it a greater buoyancy. But instead of lessening the specific gravity of the buoy by filling it with condensed air, he absolutely increases it. He might compress the air to such an extent, that it would weigh heavier than the water it displaced, and, as a matter of course, the buoy would then sink to the bottom. I extract the following from Dr. Lardner's work on "Hydrostatics and Pneumatics," which may be useful to him:—

"Every increase which is given to the quantity of air contained in a vessel (by compression or condensation) produces a corresponding increase in its weight, and every diminution of the quantity of air it contains produces a corresponding diminution in its weight."

With regard to the other part of his apparatus, I think that if there were any links in the cable, or barnacles and seaweed adhering to it, there would be much difficulty in passing the cable through the groove in the sheave; and should any sudden hitch of this kind occur, the cable would very likely break before the accompanying steamers could stop—to say nothing about the almost insurmountable difficulty of keeping two steamers in a sea way, on an exactly parallel course, and at the same rate of speed.

W. G. W.

IN ANSWER TO "J. E. M." "T. HARRISON," AND OTHERS.

Sir,—In answer to "J. E. M.," in your last number, he is quite right in saying that his pistons will be pushed forward by steam in proportion to their effective, not superficial area, but, in all the cases he has shown, the effective area is the same, viz.:—

The diameter of the cylinder, and the different shapes cannot possibly make any difference in the action of the steam, except the one marked F, and in that case the effect would be to wear one side of the piston immensely faster than the other.

In reference to Jas. Morrison's letter on "Lap and Lead," the subject being very interesting and important, I should like a little explanation.

By "throw of the valve," does he mean its travel, or half its travel, or, in the event (as in common slotted links, with eccentric rods connected at the ends) of the throw of the eccentric not corresponding to half the travel of the valve, which dimensions should be adopted as a basis for the construction of the diagram. There must be some mistake at the end—"the line G, J, F=the angular advance of the shaft." This cannot be the case, or the eccentric would be at right angles to the crank. I suppose J. M. means that if the line of the crank be at right angles to G, I, F, then A, G, C, will be the proper position for the eccentric.

In answer to Eccentric's question, I should say that rules to find the lead are useless. I know in engineers' shops it is seldom settled scientifically, but varies according

to the size and nature of the valve from $\frac{1}{32}$ to $\frac{3}{16}$. I can

vouch, however, from experience, for the accuracy of the following table for finding the lap.

To cut the steam off when the piston has passed through

1	7	2	3	5	7	11
2	12	3	4	6	8	12

of its stroke, multiply the given stroke of the valve by:—

.354	.323	.289	.250	.204	.177	.144
------	------	------	------	------	------	------

and the product, less half the lead, is the lap required.

In answer to T. Harrison, "Willis's Mechanics" has been out of print for a good many years, and is very scarce; at least, I have not been able to procure a copy after a most diligent search through all sorts of book shops.

In answer to Tyro—the use of two, three, or more threads (of the same pitch) on a high-pitched screw is to lessen their liability to strap, which is done just in proportion to the number of threads.

Hoping this letter may be of as much use to some of your subscribers as their answers have at various times been to me.

A. K. B.

P.S.—Kilmarnock, Mr. Jackson, &c., are at cross purposes about the angles of lathe centres. The former refers to the angle at A, the latter to that at B.

It is evident that if A = 45°, B must = 90°, as the three angles in any triangle are equal to two right angles.

MAHOGANY DYE.

Sir,—In answer to X. Y. Z., who requires a dye for mahogany:—

First, plane the wood (which should be of a close grain) perfectly smooth. The wood is then to be rubbed with diluted nitrous acid. Afterwards, one ounce and a half of dragon's blood, dissolved in a pint of spirits of wine, and one third of that quantity of carbonate of soda, are to be mixed together, and filtered, and the liquid in this state is to be rubbed, or, rather, laid on by a soft brush. The surface will assume the appearance of an artificial mirror; but if the polish becomes less brilliant, by rubbing it with a little cold drawn linseed oil, the wood will be restored to its former brilliancy.

B. H. HONAYSETT.

MOMENTUM.

Sir,—I wish to know the weight of rim of a fly-wheel for an engine, the cylinder 3in. dia., 8in. stroke, and fly-wheel 25ft. external dia., 150 revolutions per minute. I have tried the rules of Burgh, Molesworth, Bourne, and others, and find them to vary from 1 cwt. to 7 cwt.

Wishing to try by the law the power or momentum of moving bodies, I found in Bourne's catechism, (4th edition, 1856, page 10), "That the power inherent in a moving body of any weight, is proportionate to the square of the velocity. Of two balls, therefore, of equal weight, one moving twice as fast as the other, has four times the mechanical force. If the speed of a fly-wheel be doubled, it has four times the power it had before."

At page 11 of the catechism I find that in practice when the power resident in the fly-wheel rim, at its average speed, is from 2½ to 4 times greater than the power generated in one half-stroke, the engine will work with sufficient regularity for most ordinary purposes, but where great regularity is required it will be advisable to make it six times." Now suppose the piston to be a weight of 540lbs. moving 3½ ft. per second, and fly-wheel 25ft. mean dia., moving 21ft. per second. 6 times the speed of piston, I infer, according to Bourne, it will have 36 times the momentum; consequently piston=540lbs×3½=1,990lbs. momentum.

Fly-wheel moving 6 times the speed, which squared is 36; 1,990÷36=55.27lbs weight of rim to equal momentum of piston, which only requires multiplying for the ratio of power wanted.

If any of your readers will explain whether I am right or not, they will oblige

THOMAS WIDDER.

PROTRACTING T-SQUARE.

Sir,—Enclosed is the sketch of a protracting T-square I have found useful, and doubt not but that it may be found useful by many. If it be known (as I suppose it is not) it is not so well known as it should be. If it be new, you may give it to those who want it through your columns. A and B are the ordinary blades, and fixed stock. C is a stock moving as usual on the clamp screw pin D. Into the inner

face of this stock there is a semicircle of planetree (3½ inches radius), indented, which is divided into degrees, and figured from 0 at E, E', to 90°. There are spaces cut through the fixed stock at F, F'; these are sloped to the centre, and laid with planetree, on which lines are drawn for reading off the degrees on the semicircle. G, G, are spaces in the semicircle, cut out for the fingers. It is useful for laying down, or reading off, angular lines, drawing polygons with any number of sides, shading at various angles in one or two directions.

GAMMA (Glasgow).

OPTICIAN'S CEMENT.

Sir,—In answer to R. W. (Oct. 6), Canada balsam is the cement used by opticians for cementing lenses together.

OLD CHARLIE.

[Gamma, in answering, says:—"A drop is put on one glass; the other glass is laid on top—both slightly heated, and pressed together. One uses gum-benzoin, dissolved"]

DANIEL'S BATTERY.

Sir,—I beg to thank those gentlemen who kindly answered my enquiry respecting Daniel's battery, and I have now reversed it, and have it in this form: six earthenware jars, and placed in each a cylinder zinc; amalgamated in the centre of each zinc is a porous tube which is half inch apart from the zinc; all round in each porous is a flat strip of copper connected to the next zinc. I have put water between the zinc and porous tube, and in the tube is a strong solution of sulphate of copper. I have had it thus two days, and as yet not any signs of electricity. Can any reader give me further information?

ALFRED CROFTS.

MISCELLANEOUS ELECTRICAL NOTES.

Sir,—To "H. Brown," No. 27.—Ladd, No. 11 and 12, Beak-street, will probably give you all the information you require relating to electric sparks. You are not very explicit as to your exact requirements. If you merely wish for sparks at intervals, a few couples of Daniell's, joined in circuit with your condenser, or secondary batteries, will perhaps be sufficient. If you want a continuous spark ¼ inch long, you will find it expensive, with batteries alone.

J. Round had better apply to the same agent.

A popular work on electricity would most likely answer Comus's requirements. Lardner's "Handbook" is just the thing.

T. B. R.—It is not exactly necessary to insulate the wires comprising the iron core of induction coils, but it is frequently done in some of the more expensive descriptions, in order to increase the rapidity of charge and discharge when in use.

Knobsick, No. 28, must refer to No. 21 for a description of method of electrotyping iron with copper. If he wishes to electrotype or electro-gild, the better plan would be perhaps to coat with copper first. Napier's "Electro-Metallurgy" is one of the best works on the subject.

J. Newton, No. 29, will find an answer respecting sparks from magneto machines in No. 27.

J. W. Merthyr can obtain carbon batteries and models of electro magnetic engines, either at Faulkner's, Foster-lane, or at Horne and Thornthwaite, Newgate-street. The prices of these instruments vary from £1 upwards.

I must remind J. D. E. that electro-magnets are not often used for giving shocks. A modification known as the induction coil is more frequently used for this purpose, and has been fully described by your correspondents in previous numbers. It may, however, be useful to some of your correspondents to know how the electro-magnet can be used for giving shocks; I will, therefore, give the information:—Wind the horse-shoe in the usual manner, with say 1lb. of No. 35 copper-wire, placed over the poles and armature contact breaker, similar to those used for induction coils. Join one pole of a 6 or 12 cell Daniel, to one of the ends of electro-magnet, connect the other end to one side of the contact breaker, and to the other side of breaker, join the 2nd pole of battery. To give shocks it is only necessary to connect a wire from either side of contact breaker to the person desirous to receive them.

The strength of the shock may in some degree be regulated by attaching a spiral spring to the armature, so that the electro-magnet may have a greater resistance to overcome before attracting it; this has the effect of causing the armature to make and break with greater promptitude and rapidity.

Without going as far as Admirer in my appreciation of Mr. Tonkes' talents, I cannot help remarking that the knowledge displayed by this gentleman on electrical matters is highly creditable, especially if he has acquired it without the aid of books.

EDWIN FURZE.

CRANK TURNING.

Sir,—In reply to "Systematic," as to crank turning, turn each end of crank shaft to any given size, leaving a shoulder at the end of the cut or trued part. Bore a hole in one end of two pieces of rough cast or wrought iron, to fit, and

key-tight on each end of crank shaft; the pieces must be strong. Key the pieces A on in a line with the crank journals, and find the centres on the pieces opposite the required centre C of crank journal; B is a piece of wood used as a stay.

J. M.

AIR PUMP VALVES.

Sir,—In reply to J. Bacon, turn down the top of the piston (of brass) for a short distance, say, three-sixteenths of an inch to about five-eighths of an inch diameter, and turn a small groove near the top, so as to make it something like the neck of an old-fashioned phial. Drill a hole through the centre about the tenth of an inch diameter, over which place a strip of bladder about three-eighths of an inch broad, and tie it on by a bit of silk in the groove. Construct the bottom valve in a similar manner.

WM. TAYLOR.

A new material for paper making has just been discovered in France. With the root of lucernes M. Caminade has succeeded in making a pulp which can be employed jointly with rags in the manufacturing of paper, and even separately.

IMPROVEMENTS IN THE CONSTRUCTION OF BATTENS FOR WEAVING.*

This invention of John Thomas Cook, of Leicester, consists in adapting to the shuttle races of looms employed for plain and figure weaving, and for the manufacture of elastic web, certain novel and improved mechanism for driving the shuttle.

Fig. 1 represents an elevation of the back of the batten and shuttle race of a loom suitable for weaving narrow goods, such as elastic web, showing the improvements adapted thereto. Fig. 2 is a plain view of the shuttle and batten, and portions of the shuttle race, showing the method of connecting the shuttle with the improved mechanism for throwing the shuttle across the loom, and through the shed of the work. Figs. 3 and 4 respectively exhibit transverse and vertical sections taken through the line A, B, and C, D, of Fig. 1.

A, A, are boards forming, by the spaces at a, a, the shuttle race of the loom; B, B, are brackets for holding the boards A, in proper position; C is that part of the batten which beats up the work at each shed of the warps; the upper part of C takes into a slot formed in the tube D, and the lower part rests in a recess formed in the piece E, to which piece the brackets B are securely fixed. G is a long spindle supported by, and working in bearings formed in the brackets B; H, H₁, are cylinders having helical grooves, or quick-threaded screws, formed around them; these cylinders have a hole formed through the centre of each, in the direction of their length, so that when said cylinders are passed on the spindle G, and tightened thereon by the screws c, c, the aforesaid spindle and cylinders will revolve together upon rotatory motion being imparted thereto, either by an endless strap or band passed over the pulley I, or by other convenient and suitable means; K is the shuttle carrying the cop containing the weft in the usual way. For the purposes of this invention studs or pins d, e, are fixed into the back of the shuttle near each end thereof, and take into the grooved helices formed around the cylinders H, H₁; care being taken to so arrange them with respect to the helical grooves in the cylinders H, H₁, that when the shuttle is thrown across the loom, and through the shed of the work, in the act of weaving, one of the pins shall not leave its respective grooved cylinder until the other pin has entered into the helical groove of the other cylinder. In order to obtain great velocity of the shuttle, the grooved helices should be made of such a pitch that one revolution of the loom shall produce two revolutions of the cylinders H, H₁, during which time the shuttle will be thrown twice across the loom.

The patentee claims "the general combination and arrangement of the parts above described, and especially the helical grooved cylinders H, H₁, and studs or pins d, e, as constituting improvements in battens for weaving."

IMPROVEMENTS IN STEAM POWER IN CULTIVATING LAND.*

The invention of Henry Septimus Coleman and Alfred George Edwin Morton, both of Chelmsford, relates, first, to a novel application of two steam engines (one at each side of a field) in the traversing of two implements to and fro in tilling the land, such engines both operating simultaneously on the same circuit of rope or ropes by which the implements are propelled.

The invention relates, secondly, to a peculiar construction of drum or rigger for communicating the power from the engine's to the traction ropes of agricultural implements, whereby endless ropes can be used, and at the same time a sufficient holding power is provided therein for the purpose required, the peculiar construction of drum permitting of the rope passing more than once round it.

Fig. 1 is a diagram showing the improvements

* From *Newton's Journal of Arts*.

in the application of steam power to the cultivation of land. a, a', are the engines placed at the headlands. With the exception of the rope drum, they are of the usual construction, but may, of course, be each of less power than where only one engine is employed. b, b', are the two implements; c, c', are the ropes passing round the rope

power of engine a, for instance, will be transmitted directly to b. (the implement in operation) by the rope, c, while the power of the engine a', will be transmitted directly to b'. (the implement out of work) by the rope c', but which will be in excess of what is required for producing the retrograde motion thereof; the surplus power will consequently be

COOK'S WEAVING.

FIG. 4.

FIG. 3.

FIG. 2.

drums of both engines: these ropes are shortened or lengthened by taking up or letting out at the points where attached to the implements, and according to the distance apart at which the engines are disposed. The implement b, operates from the middle of the field to the engine a, on the left, and the implement b', operates on the land from the middle point to the engine a', on the right, the retrograde movement of

rope c, shown by dots, encircling the drum, lies, by which it is kept in parallel coils. The teeth of the pinions f, take into a stationary screw thread p, fixed on the bottom of the stud d, which controls the position of the pinions, and which by the rotary motion of the drum imparts a slow rotary motion to the pinions f, on their axes h, the amount of such motion being equal to the distance from one tooth to another of the pinions f. Thus the required position of the rope on the drum is uniformly maintained throughout its action, and as indicated in dots in fig. 2.

The patentees claim, "First,—the combination described, in which the power of two engines is applied to two distinct agricultural implements, in the manner described. Second,—the combination, arrangement, and operation of parts represented and described, with reference to figs. 2 and 3, constituting a hauling rope drum, and its application for the transmission of power applied to agricultural implements."

ASTRONOMY.

PHOTOSPHERE OF THE SUN.—Mr. Fletcher was enabled to observe the disc of the sun to great advantage during this summer. Finding no spots of sufficient magnitude to arrest his attention, he turned the telescope on the surface of the sun itself, and with the help of Dawes' solar eyepiece, armed with a power of 410 and an aperture of a quarter of an inch, saw all the features admirably. He found the entire surface, on each day when it was examined, covered with minute white granules, and although the "rice-grain" comparisons of Mr. Stone are very felicitous, yet the shapes were too various to be accurately described by any general term. They have sometimes been kept in view for a space of from ten to fifteen minutes without any change in situation or form being perceptible. None of that peculiar appearance of interlacing could be detected, unless when the air was tremulous. Mr. Fletcher is of opinion that the granules are not "entites" at all, but only some

portions of the sun's luminous atmosphere delevate into the outer or non-luminous atmosphere. They were estimated to be about two or three seconds in length, and about a third of that quantity in breadth, but no general form could be distinguished, and there was no tendency to elongated forms. If such were the shapes observed, he concludes that no interlacing could be perceived unless the granules were discs of extreme thinness; but no such structure could be imagined. Mr.

the one implement taking place while the other is in work. The implement moving backwards does so in each case on the unbroken ground. The implement b, is represented as in work while implement b', is moving backwards. Each of the implements b, and b', is, of course, supported to represent a combination of ploughs, scarifiers, or other instruments combined in one frame, as is well understood.

By this arrangement it will be readily understood that, with both engines working simultaneously, the

Fletcher thinks that those phenomena were well known to Sir W. Herschel, and that they are fully described by him in the "Philosophical Transactions" of 1801. The drawings which accompany that paper seem to confirm that opinion.

SWEDENBORG.—No. I.*

Sir,—I am glad to find that one influential journal at least is courageous enough to give admission to a biography of a man misunderstood by the age in which he lived, and whose merits are only beginning to be recognised: and also for the opportunity given me to set before your thousands of readers what little it is in my power to give respecting the life and works of one who was most emphatically the "friend of the people." But I would have the reader understand that I do not profess to render an essay warranted to come scatheless from the critics—the necessities of a business in which close application is a primary necessity prevent my paying attention to the requirements of the Academy. I would, however, express the hope that what I have collated and am about to exhibit may not cause your inquiring correspondents to regret the expression of their curiosity; and should the result of their perusal of these necessarily brief papers be the creation of an interest in their subject, I shall be amply repaid for whatever of time and labour has been expended thereon. E. C.

At Stockholm, on the 29th of January, 1688, the wife of the Bishop of Skara, Westrogothia, gave birth to Emanuel Swedberg—named Swedenborg, when, in 1719, he was elevated to the rank of nobility. It should be stated, however, that at the time of this addition to his family, Swedenborg's father was only chaplain to a cavalry regiment of the Guard, also, that he was a great patriot—exhibiting his patriotism in an eminent degree at a time when Sweden had lost her veteran armies, and "was fain to send her lads and old men into the field against the combined forces of Russia, Poland, and Denmark—while she was afflicted within by famine and pestilence." Young Swedenborg received the best classical education which the time afforded, and in 1709 took his degree of Doctor in Philosophy at the University of Upsala. In 1710 he took ship for London, where, and at Oxford, he spent a year, at the end of that time crossing over to Holland, thence journeying into France he stayed a year at Paris and Versailles, returning home in 1714. On his return he still busied himself with mathematics and mechanics, and his attainments in these sciences soon procured him an acquaintance, and an intimate connection during many years, with the Archimedes of Sweden, Christopher Polhammar, probably best known to our times as Polheim. By this connection he not only acquired great attainments in the science of mechanics, but obtained the further advantage of partaking of the confidence with which Polhammar was honoured by the celebrated Charles XII. The diploma appointing him to his office of Assessor Extraordinary of Mines in 1760, states that the King had a particular regard to the knowledge possessed by Swedenborg in the science of mechanics, and that his pleasure was that he should accompany and assist Polhammar in constructing his various mechanical works. His Majesty often made use of the knowledge and talents of the two geniuses, which in both of them, especially on the subject of mechanics, were accompanied with the gift of the most happy invention. This is not the place to speak of the works of Polhammar, otherwise there might be mentioned the famous dyke of Lyckebý, the locks of Trolhätta, the basin of Carlscrona, and other works. Of such, Swedenborg executed one of the greatest importance, during the siege of Frederickschall, in 1718. He contrived to transport over valleys and mountains, by the help of rolling machines of his own invention, two galleys, five large boats, and a sloop, from Stromstadt to Iderfjol, which divides Sweden from Norway towards the South—that is to say, for a distance of 14 miles. By this operation, says M. Sædel in his "Oration," the King found himself in a situation to carry on his plans, for, under cover of these galleys and boats, he transported upon pontoons

his heavy artillery, under the very walls of Frederickschall. In the same year he published an introduction to Algebra, which was honourably reviewed in the "Literary Transactions of Sweden," for its excellence, clearness, and practicability. It is comprised in ten books, and treats on—1. The explanation of the terms employed, and the simple arithmetical processes. 2. The mechanical powers—lever, pulley, inclined plane, &c., with a variety of problems. 3. Laws of proportions, also with numerous problems. 4. Geometrical theorems, stereometry, and specific gravity. 5 and 6. The properties of the parabola and hyperbola, with numerous other problems. 7. Theory of projectiles and artillery, with problems. 8, 9, 10. On affected roots, and the integral and differential calculus. This profound work was followed by his "New method of Finding the Longitude of places by Lunar Observations." At this time it is interesting to note our author's complaint that his labours are not appreciated, that his productions "are looked down upon by a number of political blockheads as mere scholastic exercises, which ought to stand back, while their presumptuous finesse and intrigues step forward." It is only just to our author to here note that previous to this he had ventured, and with success, to publish as a poet. Much of his product has the true ring about it, though I am not aware whether it has all been done into English. In 1719, as noticed, the family of Swedenborg was ennobled by Queen Ulrica Eleonora, and our author took his seat with the nobles of the Equestrian Order, in the Triennial Assemblies of the

SWEDENBORG.

States. In the same year he published four works, the first on a proposal for fixing the value of coins, and determining the measures of Sweden, so as to suppress fractions and facilitate computation; after which he was commanded by his sovereign to draw up a mode of computing by eighths, which he completed in a few days with its application to the received divisions of coins, weights, and measures: also a disquisition on cubes and squares, and a new and easy way of extracting roots—all illustrated. The honour of introducing the differential calculus into Sweden is due to our author, as that of the decimal mode of numeration (founded on ciphers up to 64) is due to his sovereign. The second work of the four above-mentioned is a treatise on the motion and position of the earth and the planets; the third on arguments derived from the various appearances in the North of Europe, in favour of the depth of the waters and greater tides of the sea in the ancient world. The fourth is an interesting and clear little work on docks, sluices, and salt works, to which I may allude hereafter.

About this time our author contributed papers to the *Acta Literaria Suecia*, and in 1721 undertook a professional journey to the mines and smelting works of Saxony and the Hartz mountains. Besides accomplishing the principal object of his journey—though it lasted but fifteen months—Swedenborg published several important works at Leipzig and Amsterdam—among them "A Geometrical Explanation of Chemistry and Physics," treatises "On Iron

and Fire," and "Miscellaneous Observations" on subjects connected with the physical sciences, especially on minerals and the strata of mountains. At this period, according to C. E. Strutt, in his introduction to his translation of our author's "Prodromus Principiorum Rerum Naturalium"—or forerunner of a new chemical philosophy—chemistry was in a state of transition: the science possessed no uniform and definite nomenclature, as no comprehensive theory had yet arisen; and the doctrine of the Four Elements held "divided empire" with that of the Three Principles of the alchemist. Forth came Swedenborg, with a clear perception of the desiderata, with his new chemical philosophy, which he founded partly on the ideas of the ancients, concerning ultimate atoms. A characteristic of his system is the explanation it gives of the origin of saline atoms—constituting the first inert matter—in the depths of the primeval ocean, where they are presumed to have been moulded in certain interstitial spaces, vacated by the ethereal element, between the bullular particles of water. The theory treating all substances in the domain of physics and chemistry as subject to a peculiar mechanism, variety is referred to difference of position, weight, and motion. Says Mr. E. Rich ("Sketch," p. 13):—"This extraordinary attempt to bring invisible things to light has been thoroughly justified by the success which has attended Dalton's hypothesis in an age better prepared for its application; and by the equally remarkable fact that the definitions given of salts, acids, and alkalies, have gradually approximated very near indeed to those which result from Swedenborg's hypothesis. We say nothing here of a latent connection between the principle on which it is founded, and some of the results obtained by Berzelius, "whose fame, as a chemist, is as wide as the civilized world."

(To be continued.)

GENERAL NOTES.

MANUFACTURE OF IRON AND STEEL.—The object of the invention patented by Mr. S. C. Kreeft, of Fenchurch-street, for Mr. Jacopo Bozza, of Naples, is to impart homogeneity, and a compact molecular arrangement, to cast-iron, cast-steel, and Bessemer metal, and thereby give increased strength to the articles manufactured therefrom. To this end a current of electricity is applied to such metal while in a state of fusion, obtained either by means of a voltaic battery or by an induction apparatus. The electric current is applied during the running off of the molten metal, and is thereby caused to assume, while in a state of fluidity, the desired homogeneous and compact molecular arrangement which is retained after cooling. The metal thus treated acquires a tenacity very superior to that of metals manufactured in the ordinary manner. The effect of this treatment is also to give to the metals a perfect magnetisation, which renders possible the economical construction of magnets and other applications.

CLOCKS AND WATCHES.—There has been a great falling off in the number of clocks imported this year. Thus the total imported to August 31 was 149,916, as compared with 212,315 in 1864, and 196,087 in 1863 (corresponding periods). The number of watches received from abroad in the first eight months of this year was 96,401, against 87,282 in 1864, and 100,937 in 1863 (corresponding periods). The number of clocks imported will be seen, however, notwithstanding the reduction observable this year, to be still very large, and, considering that the home clock manufacture is not inactive, it is difficult to imagine what becomes of all the results of the foreign horological efforts which we press into our service.

EXPLOSIVE POWER OF POWDER.—The result of some experiments with explosive materials which are on record are almost incredible. Rumford having charged a mortar with one-twentieth of an ounce of powder, and closed every orifice with great care, placed above it a mass of metal which weighed more than 8,000lb. The result of explosion was the bursting of the mortar and the lifting of the enormous weight. In another experiment, a piece of iron which would have required a strain of 400,000lbs., was torn asunder through the explosion of 28 grains very closely confined in a cylindrical space. Facts such as these cannot fail to point to the terribly destructive power of the torpedo, if the maximum of explosive force, combined with the minimum of charge in a given space, be once fairly ascertained and tested by practical experiment. The opinion of many authorities against a gigantic system of coast fortification, points to the necessity for some cheap and efficient means of defence for our unprotected roadsteads and harbours.—*Scotman.*

* We desire it to be understood that we do not necessarily endorse all put forward by the writer: advocates for fair play, we willingly give room to a fair notice of the life of a man thought by many to have been most grossly maligned by his contemporaries and the present generation.—*Ed. M. M.*

WAKEFIELD INDUSTRIAL AND FINE ARTS EXHIBITION.—The exhibition was finally closed to the public on Saturday, on which day the number of persons admitted was 7,232. On Monday the school children were admitted, and the building presented a very cheerful and animated appearance. On Thursday the closing ceremony will take place.—*Leeds Mercury.*

TINWARE.—A ministerial order has been issued in France that only utensils tinned with pure tin should be used in the military hospitals, and M. Jeannel gives the following process for detecting small quantities of lead in tin. He treats five decigrammes of the metal filed off with an excess of nitric acid diluted with three times its weight of water, boils the mixture, filters, and then drops into the solution a crystal of iodide of potassium. If only one ten-thousandth of lead is present, a yellow precipitate is formed, which does not disappear on adding an excess of ammonia.

TO BRONZE ZINC STATUES, &c.—Make a solution of six parts chloride of antimony in one part of alcohol and four parts hydrochloric acid, and apply it to the object with a brush. Wipe the figure over with a wet cloth, and then apply the solution a second time. Now dry the object as quickly as possible in a warm place. When it is perfectly dry rub it all over with oil.—*Deutsch. Illust. Gewerbeztg.* 1864.

STEEL FOR SHIPBUILDING.—A vessel which has just arrived at Liverpool is said to afford a remarkable instance of the value of steel as a material for shipbuilding. This vessel rode out the cyclone at Calcutta last year. She was run into twenty times, and her plates twisted in every direction, but not one was cracked.

A gigantic steam road locomotive, which was brought to Belfast from Fleetwood to work in connection with the quarries at Newcastle, county Down, was driven through Belfast last week, and attracted large crowds of spectators. The works are massive and elaborate, and the machine is calculated to carry 80 tons with ease.

We learn that the German astronomers have agreed to give the name of Clio, the muse of history, to M. Luther's new planet, the eighty-fourth of the series, discovered on the 27th of August last. It has been observed at Bilk, Cracow, Berlin, and other places, so that its orbit will soon be calculated. We also learn that M. Goldschmidt has rediscovered the planet Diana.

The English mix chloride of potash, the French nitrate of potash with the fulminating mercury used for filling percussion caps. The English are less liable to corrosion than the French.

The quantities of tin, copper, and lead ores produced in Great Britain last year were 15,211 tons, 214,604 tons, and 94,433 tons respectively. From the lead 641,088 ounces of silver were obtained.

Mr. HUGGINS states that from spectrum observation he has made he is led to believe that the stars closely resemble the sun, and that the source of their light is probably solid matter in a highly incandescent state.

ARSENIC has been proved to be almost invariably present in the ochreous deposit thrown down by water. Professor Otto readily discovered its presence in the crust which had formed on the inside of his tea-kettle.

PROFESSOR WEDL found, on examining some sections of teeth that had been macerated for a few days in water, that they were attached by fungous cells resembling mushroom spores. They perforate the ivory, but not the enamel.

Dr. FRANKLAND ascertained that one gallon of mineral oil was equal in illuminating power to 18lb. of paraffin candles, 22lb. of sperm, 26lb. of wax, 27lb. of stearine, 29lb. of composite, or 39lb. of ordinary tallow candles.

Mr. DAWES has discovered certain features in the planet Mars, which, from their appearance, he describes as a long narrow strait running N.E. and S.W. with two wide mouths of rivers, which he, however, could never trace.

Dr. SJOGREN, a Swedish naturalist, states that the particles of pure iron found in the Swedish lakes result from the deoxygenizing action of certain insects. Their larvae absorb oxygen from the oxide of iron and form a cocoon of pure metal.

By order of the King of Sweden, experiments with submarine infernal machines are about to be tried on the old ship of the line "Charles XIII."

The finance of the late East London Working Classes Industrial Exhibition turns out satisfactory. The expenditure was £377 4s. 7d., the income £377 14s. 5d.

ELECTRICITY.

NOVEL EXPERIMENT.—It is undoubtedly a matter of considerable importance in many harbours that it should be known with certainty by those about to enter or leave, when there is a sufficient depth of water for the purpose. M. Emile Duchemin has devised a very simple application of electricity, which answers admirably for this purpose. He attaches to a small float a plate of carbon and a plate of zinc, and connects these respectively with the wires of an electric bell-ringing apparatus. Throwing the float and battery into the sea will cause the bell to ring. When therefore they are suspended at any required height, within reach of the tide, as soon as the water has risen sufficiently to set the small battery in action, the bell will ring; and thus the apparatus may, at pleasure, be made to indicate any state of the tide. By using a sufficiently large float and battery, it is evident that an electric current will be generated sufficient to sound a bell of considerable size, or, by means of Geissler's tube, to produce a light which will be seen from a great distance.

PROFESSOR WHEATSTONE ascertained that the duration of the electric spark does not exceed the twenty-five thousandth part of a second. A cannon ball would appear stationary in its flight if illuminated by the spark, and the wings of an insect that move ten thousand times a second would seem at rest.

CHEMISTRY.

TEST FOR OTTO OF ROSES.—Hager mixes five drops of the otto to be tested with twenty drops of pure concentrated sulphuric acid. Whether the oil be adulterated or not, a thick yellowish brown or reddish brown mixture results. When this mixture is cold, it is shaken up with three drachms of absolute alcohol. If now the otto is pure, a tolerably clear yellowish brown solution results, which, after heating to boiling, remains clear. But if the otto is adulterated with geranium, palm rose, or pelargonium oil, the solution remains very cloudy, and in some cases a darker fluid separates, in which a deposit forms. On heating this solution, the sediment melts together, and from the size of the mass the author infers the degree of adulteration. If, for example, the mass has one-fourth the volume of a drop, he concludes that the otto was mixed with at least one-third of foreign oil. If the otto is adulterated with spermaceti, this substance separates and floats on the surface of the solution, or remains suspended in the liquid as a scaly crystalline mass. The above test is founded on the circumstance that pure otto of rose forms, with strong sulphuric acid, a resinous substance, which is completely soluble in absolute alcohol; while the substance formed with other oils is only partially soluble. Gubourt has observed that the odour of pure otto is not affected by mixture with strong sulphuric acid, but if other oils are present a disagreeable odour is developed.—*Zeitschrift, fur Analyt. Chem.*, No. 4, 1864, p. 479.

SCHULTZ'S WHITE GUNPOWDER.—This is trinitrocellulose, prepared from saw-dust by the following process. The saw-dust is first boiled for three or four hours with a weak soda solution, and then boiled a second time with a fresh lot of the same solution. It is then washed in running water, afterwards steamed for fifteen minutes, and then again washed in running water for twenty-four hours. It is now bleached with chlorine or chloride of lime, boiled in water, once more washed in a stream, and now dried. The saw-dust is now ready to be treated with nitric acid. For this purpose a mixture of 40 parts strong nitric acid (1.48 to 1.50) are mixed with 100 parts of sulphuric acid (1.84); and the mixture is allowed to stand two hours to cool. One hundred parts of this mixture are then placed in an iron vessel, around which a stream of cold water circulates, and six parts of the saw-dust are gradually added, stirring all the time. The saw-dust is allowed to remain in the acid two or three hours, the stirring being continued. After this time the whole is transferred to a centrifugal machine, and the acid separated. The wood is then washed for two or three days in cold water, afterwards boiled in a weak soda solution, again well washed in cold water, and then dried. It is now ready for the final operation, which consists in soaking it for ten or fifteen minutes in a solution of 26 parts of nitrate of potash in 220 parts of water. After this, it is carefully dried at a temperature not exceeding 44° C.; the very fine dust is then separated by means of a drum sieve, and the remainder is ready for market. *Chem. Central Blatt*, No. 44, p. 704.

THE MANUFACTURE OF PYROGALLIC ACID.—A very valuable process has been discovered in France, whereby the pyrogalllic acid, so largely consumed by photographers, can be made in much larger quantities and cheaper rates than hitherto. By means of the old process 100 parts of gallic acid yielded but 25 or 30 per cent of pyrogalllic acid. By the process just been made known to the Academy of Sciences at Paris, by M. de Luynes, 100 parts of gallic acid are made to yield 60 parts of pyrogalllic acid. The new process is a somewhat complicated one, and the pyrogalllic acid is first formed in solution instead of in its usual state.

M. D. GERNEZ states that he distilled some water in a platinum alembic twice, and then caused it to be traversed slowly by air drawn by aspiration in the middle of the park at Talmay, at a great distance from any habitation. Some drops of the water, when submitted to evaporation on a slip of glass, left behind microscopical crystals resembling those of sulphate of soda, and others upon which M. Gernez could not pronounce.

NOTES ON PHOTOGRAPHY.

UNEQUAL INTENSITY IN NEGATIVES BY THE NEW DEVELOPER.—Our esteemed correspondent, Mr. Burgess, of Norwich, says *The Photographic News*, writes as follows:—"I have frequently found, since using the gelatino-iron developer, that on varnishing the negative, some parts remained more intense than others (generally little patches on the background), apparently arising from the varnish not having penetrated at those parts. A second application of the varnish always causes these more intense patches of varnish, and a prolonged washing before drying avoids them altogether." Perhaps this will be of service to G. U. N., and any others who may have met with a similar effect.

MAGNESIUM LIGHT FOR COPYING PAINTINGS.—We understand that Mr. Thurston Thompson has recently photographed Maclean's "Death of Nelson," recently finished in the Royal Gallery at Westminster. The light was supplied by burning magnesium, the lamps used being those of Mr. Solomon.

PHOTOGRAPHS OF THE ECLIPSE OF THE MOON.—At a recent meeting of the Photographic Section of the Literary and Philosophical Society, Mr. A. Brothers submitted a valuable series of instantaneous photographic negatives, taken by him during the progress of the late eclipse of the moon. The total number of negatives is twenty, of which sixteen represent the progress of the eclipse. An attempt was made, by the exposure of a one-plate for fifteen seconds, to obtain the darkened limb of the moon, but no photographic action resulted. In mentioning the name of Mr. Brothers we are reminded that his name is mentioned in the report of the photographic jurors at Dublin, in connection with some complimentary remark on his photographs by the magnesium light, as "Messrs. Brothers," instead of Mr. A. Brothers.

PHOTOGRAPHS OF THE CHINESE GIANT.—The London Stereoscopic Company have just issued a series of capital photographs of the famous Chinese giant *Chang*. Some in which the wife of the giant is portrayed by his side give a more striking illustration of his immense proportions than could be effected by any other method; others with the dwarf by his side gives a ludicrous effect to the pigmy stature of the latter. We understand that it is the intention of the Company to have one of the portraits enlarged to life-size, 7 feet 8 inches, thus obtaining the largest photograph which has probably ever been produced. The excellence of the card pictures afford facility for a very fine enlargement.

ORIGIN OF PHOTOGRAPHY.—In connection with this subject, to which we have referred once or twice lately, we may mention a piece of collateral evidence which recently came under our attention, which strongly aids in establishing the claims of the Rev. J. B. Reade to the use of gallo-nitrate of silver some years before it was patented by Mr. Talbot. Mr. Reade told us that one of his early photographs, produced in the solar microscope on the paper prepared with chloride of silver and washed with an infusion of nut-galls, was an enlarged copy of a flea, which he gave at the time to Mr. Akerman. Mentioning this circumstance to Dr. Diamond, he told us that the same photograph was given by Mr. Akerman to him the Sunday on which King William IV. died, the circumstance being impressed on his mind by hearing, shortly after receiving the picture, the bell of St. Paul's toll, and the exclamation being made that some member of the royal family must be dead. This, it will be remembered, was in June, 1837. The photograph in question, Dr. Diamond states, had all the peculiarity of the early developed prints.—*Photographic News.*

OVAL CHUCK, &c.

Sir,—Herewith I send, according to promise, drawings of oval chuck, to which I append others of a simple eccentric chuck, which any amateur can fit up for himself. Letters have not been placed on the various portions, but the following explanation, it is hoped, will prove quite intelligible. An oval (ellipse) is produced in this chuck upon the principle of adding two crescents to a circle, one to each side. As the object approaches the cutting tool, it is gradually thrust forward by an eccentricised ring acting on a sliding plate in the chuck, and then gradually withdrawn; this takes place twice during each revolution, and an oval is the result. Figure 4 is a top-view shewing the chuck, its projecting nose similar to that of the mandrel, the jaws to embrace the ring, the ring in front of the face of the headstock, the screws to secure it there, and the bent plate or staple passing to the rear of the right hand upright of the head stock, through which staple the screws pass.

Fig 1 gives back view of chuck, the sliding portion of which projects to the right. The centre boss is that into which the mandrel-nose is screwed, and on each side are the projecting jaws which are fastened to the sliding plate. The dotted circle marks the position of the ring, see fig. 3, and the four small circles are the tail-ends of four screws which fasten two slider plates at the front of the back-plate of the chuck. Fig 2 is the chuck viewed in front, the centre boss is the nose of chuck, the two screws in a line with this are those which secure the jaws for the ring; the other four screws near the edge fasten the two fillets to back plate. These

fillets have V-shaped grooves in one edge, along which the slider moves; they are somewhat thicker than the slider, so that the latter does not rub on the back-plate; each one has also the heads of two screws, working in edge of back-plate, pressing against it, to make up for wear in the slider and fillets.

The two jaws to the ring have also set pins in them, the holes for which, in the slider, are placed half a diameter nearer the middle than their true position would be, and the pin is filed one-half away to allow them to enter. Inserting a pin with less of its substance filed away and easing the screw-hole in slider, will make the jaws fit close to the ring as it wears. The two plates and staple can be of cast iron, the fillets and ring of gun metal, the jaws of case-hardened iron or steel. The usual lathe chucks fit on the nose of the slider, a flat piece of well-seasoned plane with a piece of box wood inserted at the centre in which the female thread is chased, forms a very useful one for picture frames.

The eccentric chuck (inventor unknown) is drawn in figures 5, 6, 7. The first of these is a front view shewing (1), two slips of brass between which an oval piece (2), slides; a circular piece (3) edged by 2, to which the block for chucking is secured by three screws entered at the back. The slips 1 are fastened to the lignumvite or box body by two wood screws each. The oval piece, 2, whose ends are cut off square, has a hole in it large enough to fit 3, and is secured by a screw-bolt at each end. These screw-bolts move in slots cut through the chuck, and so allow the centre of 3 to be placed eccentrically to the axis of the mandrel. The edges

of 1 are graduated for counting this eccentricity. A common division is into 1-120th of an inch. The circular plate 3 has rivetted into it an axis passing through a tongue, which is so fastened that turning the winged nut pulls it down in its recess, and makes 3 firm on its seat. The tongue is screwed loosely in position at one end, and has the bolt for winged nut at the other; it has through it a slot, one end of which is enlarged to admit the head of the axis of 3, the central part of which can glide along the slot. Round the circular hole in 2 are marked divisions, 96, 100, 144, or 192, to serve as a click or counting-plate. Some kind of slide rest or tool holder is requisite, or the rings in one circle of ornamentation will not correspond. Fig 6 is a side view with the tongue dotted out, and the chucking screws projecting upwards. Fig 7 is a section across the tongue-recess. The portions 1, 2, 3, are of brass, the tongue, axis, and bolts of steel. All the figures are about one-fifth of the real size. H. HURST.

At the last meeting of the Literary and Philosophical Society, Mr. Dyer, referring to the breaking of the Atlantic Cable, expressed his surprise that no apparatus had been provided to seize and secure the end of the cable when the rupture took place, as contrivances for a similar purpose were in use in almost every cotton mill.

Sounds are distinct at twice the distance on water than they are on land.

MACHINERY AT THE DUBLIN EXHIBITION.

We have not yet had space in which to notice the very excellent "prize" turret clock by Booth and Son, Dublin. The principal feature in it is the "train remontoire" motion—designed to obviate disturbances originated in the exposure of large hands to the force of the wind, &c.: in other words, it cuts off from the escapement all the excess of power which of necessity is requisite for overcoming the retarding forces operating on the hands. This arrangement, then, consists of a spring, similar to that in a musical box, attached at one end to a carrier so designed as to rotate, and at the same time to be stopped at any given position. The other end of the spring is attached to the axis of the escape wheel. The spring, which is set up by the carrier, is released every thirty seconds with the requisite tension, propels the wheel, and, by the pallets, gives the force requisite to keep the pendulum swinging; once it has been set in motion. Varying friction is thus disconnected from the pendulum, and great uniformity in its vibrations follows. The small force necessary to drive a pendulum is shown here. The pendulum is 14½ feet long from its hanging point, and weighs 3 cwt.; the impelling force acting on the pitch line of the scape wheel (4in. in diameter), is only 1½oz. This clock has kept time in the building since May, and gains but 7-10ths of a second per week. Its hands are driven by an independent shaft, upon which a pinion is mounted—its diameter being one-third of the main wheel with which it is in gear, and is fitted so that the shaft can turn within it, and so allows of the clock being set without disturbing the remainder of the works. Discharging, locking, and counting is effected by one lever, in place of the many complications usually employed to attain the same end.

Messrs. Courtney, Stephens, and Co., Dublin, exhibited a punching machine with shears combined—driven by a small engine attached to the frame of the machine, which works smoothly, and punches holes up to 1½in. diameter, and through plates up to 1½in., with seeming ease. A simple and somewhat peculiar arrangement is exhibited whereby the operative can prevent the punch from working, while the machine is in motion, until the plate is set perfectly accurate. This is effected by a wedge-shaped piece of iron placed in juxtaposition with the man's hand, and, by its aid, half a second suffices to throw the punch out of gear. It will be evident that, with this at his hand, the workman can drive his machine at a quicker rate than formerly. The same firm exhibit a spur wheel just as it was taken out of the sand, without being operated upon by hammer, chisel, or file—as a specimen of good casting for accuracy of make and appearance of metal. It is moulded by a peculiar process, without a model; and the firm use this process for moulding all the gearing.

A handsome model of a compound governor is exhibited by the Messrs. G. and J. Weir, of Glasgow, which seems very sensitive in its working; and Mr. J. Byrne, of Dublin, shows one of his patent adjustable governors. This latter has four pendulums, but the number may be varied—the principle of construction being that the centrifugal force of the revolving pendulums is equilibrated at any required speed by the force of gravity of an adjustable counterweight or the tension of a spring. As to the number of pendulums it is considered to have Mr. Byrne's governor constructed with four, each with a crank springing from the joint at right angles, which are connected by means of rods to a sliding cylinder, having a steel centre let in at top. By this means the divergence of the pendulums raises the sliding cylinder, which, acting on the steel centre, gives motion to the valve; and when the engine at work receives a check through work being suddenly put on, the pendulums lose some of their sustaining power, of which the counterweight takes advantage by depressing them, and so admitting a greater supply of steam, which checks the error; or when work is taken off and speed increased, or steam pressure is increased, the pendulums acquire more centrifugal force, increase the angle of divergence, raise the counterweight, close the valves, and so reduce the supply of steam until the speed is checked.

Messrs. Courtney, of Dublin, exhibit pumps of different descriptions, one on the slide-valve principle showing considerable ingenuity, and somewhat resembling the engine which drives it. It is double-acting, and raises a gallon of water each revolution, the proper speed to drive being about 100 revolutions. It is now largely used on railways for supplying locomotives. But, respecting nearly all the Irish exhibitions it may be said that their display is extremely creditable.

SCIENTIFIC AND MECHANICAL INVENTIONS.

IMPROVEMENT IN AIR TUBING.—A valuable improvement in the manufacture of flexible air tubing has recently been adopted by Mr. Ellis Lever, the original inventor. In place of bevelled or flat iron hoops he substitutes a series of rings of round iron or steel, for the purpose of keeping the tubes open. These rings, instead of being welded, are so united that when pressed they yield, and can be reduced to one-third the original size; but immediately they are released become a perfect circle of the exact size of the tube. The tubing so made is said to be lighter, stronger, and less costly than the old kind.

THE NEW METAL INDIUM.—This new metal, discovered by M. Schroetter by spectrum analysis, has a striking resemblance to cadmium. It takes its name from the beautiful line of indigo blue colour which it gives, which corresponds with number 2523 on the Kirchhoff scale, and does not coincide with any black ray of the solar spectrum. To determine its equivalent M. Schroetter serves the sulphuret with an aqueous solution of chlorine, which separates it completely from the sulphur, and the chloride of indium is formed. There is not the slightest trace of indium in the solar atmosphere.

M. ARMAN, the famous shipbuilder, has submitted to the Emperor Napoleon a new cable of his invention. The principal quality of this cable is its extraordinary lightness, so that there is little danger of its breaking under its own weight.

A new invention has been brought out, called the lock-jaw cotton gin. The effect is obtained by an intermittent nipping action, and it is said will turn out work more rapidly and of better quality, there being no breakage, rubbing, or felting together of the fibres.

COPYING ONE PICTURE BY MANY NEGATIVES.—Messrs. Oundall and Downes, in a recent copy of Herbert's "Descent of Moses from Sinai," obtained the picture by no less than twenty-one negatives, the prints from which are joined with great success, so as to form one harmonious picture.

THE NEW DEVELOPER.—Mr. Cherrill suggests that the indication of the presence of free sulphuric acid in the new gelatino-iron developer will be imperfect development and the production of black spots in the negative.

A CONCENTRATED solution of chloride of zinc, which has been boiled with an excess of the oxide of that metal until it does not discolour litmus, will dissolve silk. By means of the dialyser the silk can be separated from its solvent in the form of a colourless inodorous solution.

HERZENBERG calculates 41 millions of individuals, infusoria, &c., in a cubic inch of tripoli.

An ordinary windmill has the power of about thirty four men, or, at most seven horses.

THE Prussian Government is said to draw an annual revenue of 17,000 dollars from amber.

HERSCHELL thought that the sun's luminous atmosphere is 2,500 miles from its surface.

DUBLIN

INTERNATIONAL EXHIBITION.

No. 632—CLASS D—SECTION 22.

PRIZE MEDAL

AWARDED TO

CHATWOOD'S

PATENT SAFE AND LOCK COMPANY

(Limited),

LANCASHIRE SAFE AND LOCK

WORKS, BOLTON,

FOR THEIR

FIRE-PROOF SAFES, LOCKS, &c.

WITH SPECIAL MENTION OF THE

"WEDGE PROOF FASTENINGS"

OF

S-CHATWOOD.

TO ESTABLISHED ENGINEERS AND BOILER MAKERS.

AGENTS WANTED in every Manufacturing district, for the sale and application of Messrs. Ferguson, Thys, and Co's.

PATENT NON-CONDUCTING COMPOSITION,

For preventing the radiation of heat or transmission of cold in Steam Boilers, Steam Pipes, Cylinders, and all Heated Surfaces. A very liberal Commission allowed. Apply to Messrs. FERGUSON, THYS, and Co., the Creation Works, Mile End-road, London.

SECOND-HAND CASES OF MATHEMATICAL INSTRUMENTS.

Theodolites, Levels, Pentagraphs, Quadrants, Sextants, Universal Dials, Protractors, Circumferencers, Prismatic and Beam Compasses, Ivory and Boxwood Scales, Land Chains, &c., by Troughton and Simms, Elliott, Dolland, and others, at W.M. LAWLEY'S, 73, Farringdon-street, City. Photographic Cameras, Lenses, Magic Lanterns, Slides, Dissolving View Apparatus, Microscopes, Telescopes, Opera, Race, and Tourist's Glasses, by Voigtlander, Ross, Dallmeyer, and others. Instruments bought or exchanged. Catalogues forwarded on receipt of three stamps for each.

JOSEPH STANLEY,

(Late Foreman at David Hart's.)

ENGINEER AND BUILDERS' PATTERN MAKER.

33, FIELDGATE-STREET, WHITECHAPEL-ROAD, E.

Patterns designed and arranged from instruction according to requirement.

MODELS AND PATTERNS

for
INVENTORS, MACHINISTS, AND
ENGINEERS.

Made in all their branches by

G. TAYLOR,

140, St. John-street, West Smithfield.

NATIONAL BOILER INSURANCE COMPANY (LIMITED),

ENGINEER, MACHINIST,

AND LATHE MAKER,

No. 118, RAILWAY ARCH, VAUXHALL-WALK, S.

JAMES LEWIS.

(Late Lewis & Son),

ENGINEER, MACHINIST, LATHE & TOOL

MAKER, and Modeller of New Inventions.

41, GREAT QUEEN-STREET, LINCOLN'S INN-FIELDS.

(Late of 5, Wych-street, Strand.)

Machinery made to Drawings or Patterns, and Worked out to Scale.

W. & A. GLOVER,

ENGINEERS, MACHINISTS,

LATHE, AND TOOL MAKERS,

191, OLD KENT ROAD.

SMALL SCREW CUTTING, TURNING, AND PLANING.

Fifth Edition, lately published, 8vo. cloth, now reduced to 12s. (Postage 6d.)

TREDGOLD'S PRACTICAL ESSAY ON

THE STRENGTH OF CAST IRON, Edited by EATON HODGKINSON: together with HODGKINSON'S EXPERIMENTAL RESEARCHES. With 8 plates and numerous woodcuts.

LOCKWOOD AND CO., 7, Stationers' Hall Court.

STANDARD GAUGES, Surface Plates, Straight

Edges, Scales of Length, and other Instruments of Precision, of great accuracy and of all sizes.

H. GARRSIDE, 17 Coupland-street, Oxford-street, Manchester.

SCREW CUTTER'S GUIDE,

Price 1s. 6d., or stamps.

Containing 116 Pages and nearly 2,000 Tables of Wheels, all different threads and pitches.

Tables for Tap making for Engineers, $\frac{1}{4}$ to $\frac{1}{8}$ inches, Gas Taps $\frac{1}{16}$ to $\frac{1}{8}$ inches, Mr. Whitworth's thread and make.

A Hitherto showing a new radius gear invented by the author of this work.

May be had at James Martin, 19, Wilson-street, New Cross-road, Deptford, Kent.

NEW WORKS PUBLISHED

BY

E. & F. N. SPON,
16, BUCKLERSBURY.

Just published, 8vo. cloth, price 18s.

PRACTICAL SPECIFICATIONS OF WORKS

executed in ARCHITECTURE, CIVIL and MECHANICAL ENGINEERING, and in ROAD-MAKING and SEWERING: to which are added a Series of practically useful Agreements and Reports.

By JOHN BLENKARN, Civil Engineer and Architect.

London: E. & F. N. Spon, 16, Bucklersbury.

Royal 8mo. roan, price 5s.

A HANDBOOK FOR ARCHITECTURAL

SURVEYORS, and Others Engaged in Building.

By JOHN THOMAS HURST, C.E.

CONTENTS.

Formulae useful in Designing Builders' Work.

Tables of the Weights of Materials used in Building.

Memoranda connected with Builders' Work.

Architectural Mensuration.

Constants of Labour.

Valuation of Property.

Summary of the Practices in Dilapidations.

Scale of Professional Charges for Architects and Surveyors, with various useful Tables and Memoranda.

London: E. & F. N. Spon, 16, Bucklersbury.

Just published, elephant folio, cloth, price 42 5s.

Kept also in Limp Binding at the same price (can be rolled up in a small compass without injury to the plates).

PRACTICAL ILLUSTRATIONS OF LAND

and MARINE ENGINEERS, showing in Detail the Modern Improvements in High and Low Pressure Surface Condensation, Superheating, together with Land and Marine Boilers.

By N. F. BURGH, Engineer.

London: E. & F. N. Spon, 16, Bucklersbury.

Royal 8mo. roan, 4s. 6d., post free.

RULES FOR DESIGNING, CONSTRUCTING,

AND ERECTING LAND AND MARINE ENGINES and BOILERS.

By N. F. BURGH, Engineer.

London: E. & F. N. Spon, 16, Bucklersbury.

Eighth Edition, in royal 8mo. roan, price 4s. 6d. post free.

A POCKET BOOK OF USEFUL FORMULÆ

AND MEMORANDA, for Civil and Mechanical Engineers. By

GUILDFORD L. MOLESWORTH, Memb. Inst. C.E.

London: E. & F. N. Spon, 16, Bucklersbury.

Just published, on a Sheet, price 1s.

DELANY AND OKE'S WAGE TABLES for

ENGINEERS, SHIPBUILDERS, CONTRACTORS, BUILDERS, &c., from a quarter of an hour, in regular and casual, to nine hours and three-quarters, and from one day to ten days, at 1s. to 5s. per day.

London: E. & F. N. Spon, 16, Bucklersbury.

Just published, royal 8vo., price 7s. 6d.

THE SEWING MACHINE: Its History,

Construction, and Application. Translated from the German of Dr. HERZBERG, by UPFIELD GREEN. Illustrated by Seven large folding Plates.

London: E. & F. N. Spon, 16, Bucklersbury.

600 pages, crown vo., price 10s. 6d.

PERPETUAL MOTION. Its History during

Three Centuries: with ample Descriptions and Illustrations. By HENRY DIERCKS, Civil Engineer.

London: E. & F. N. Spon, 16, Bucklersbury.

Royal 8vo., cloth, illustrated with 41 Plates, price 16s.

A PRACTICAL TREATISE ON THE SCIENCE

of LAND and ENGINEERING SURVEYING, LEVELLING, ESTIMATING QUANTITIES, &c., with a General Description of the several Instruments required for Surveying, Levelling, Plotting, &c.

By H. K. MERRITT.

London: E. & F. N. Spon, 16, Bucklersbury.

Just published, royal 4to., half-bound, illustrated by 54 Plates of Furnaces and Machinery, price 42 5s.

THE IRON MANUFACTURE OF GREAT

BRITAIN, Theoretically and Practically Considered; including Descriptive Details of the Ores, Fuels, and Fluxes employed; the Preliminary Operation of Calcination; the Blast, Refining, and Puddling Furnaces, Engines and Machinery, and the various Processes in Union, &c. By WILLIAM TRURAN, C.E., formerly Engineer at the Dowlais Iron Works, under the late Sir John Guest, Bart., subsequently at the Herwain and Forests Works, under Mr. Crawshaw. Third Edition revised from the manuscript of the late Mr. Truran. By J. Arthur Phillips, Author of "A Manual of Metallurgy," "Memoirs of Mining," &c., and W. H. Dorman, C.E.

London: E. & F. N. Spon, 16, Bucklersbury.

Just Published, post 8vo. cloth, 3s. 6d.

MEMOIRS OF THE DISTINGUISHED MEN OF

SCIENCE OF GREAT BRITAIN, LIVING A.D. 1807-8. By W.

WALKER, Jun., with an Introduction by Robert Hunt, F.R.S.

Second Edition, revised and enlarged.

Containing the lives of Watt, Binnie, Telford, Mylne, Jessop, Chapman, Murdock, the first to introduce gas into practical use; Brunford, Huddart, Boulton, Brindley, Watsan, Bentham, Maudslay, Dalton, Cavendish, Sir Humphry Davy, Wollaston, Hatchett, Henry, Allen, Howard, Smith, the father of English geology; Crompton, inventor of the Spinning Mule; Cartwright, Tennant, Ronalds, the first to successfully pass an electric telegraph message through a long distance; Charles Babbage, Trevithick, Naunth, Miller, of Darlington, and Symington, the inventors and constructors of the first practical Steamboat; Professor Thomson, of Glasgow; Troughton, Donkin, Congreve, Herschel, Mackenzie, Baily, Foddaham, Leslie, Playfair, Rutherford, Dollond, Brown, the Botanist; Gilbert and Banks, the Presidents of the Royal Society at that epoch of time; Capt. Kater, celebrated for his pendulum experiments; Dr. Thomas Young, and Jenner, the benefactor of mankind; J. J. Ivory, Dr. Priestly and Cort, the father of the iron trade.

London: E. & F. N. Spon, 16, Bucklersbury.

UPFIELD GREEN,

JOINERS' HALL BUILDINGS, 79, UPPER THAMES STREET, E.C.

THE LONDON DRAWING ASSOCIATION

FOR supplying Engineering, Mechanical, Architectural, and General Drawing, Designs, Maps, Plans, Tracings, Wood Engraving, Microtyping, &c., Duke-street, Adelphi, London. Enclose stamp for prospectus.

JOHN SHEPPARD, of 10, Marsden-square,

Manchester, has specially adapted himself for the supply of **ENGINE-CLEANING WARE**, at the following prices: White at 22s. per ton; grey, 24s. per ton; coloured, 41s. per ton. Wadding Material for Wadding manufacturers, at equally low prices. In bleached, crimson, grey, and black. Liberal terms to shippers.

FOR SALE, A Self-acting, Turning, and Screw-cutting Lathe, 10 inch centres, with bed 16 feet long; a second-hand planing machine, to plane 4 feet by 3 feet. Drilling, Planing, Shaping Machines, &c. W. Blackett, Hope Iron Works, 105, South-wark-bridge-road, London.

THE LENOIR GAS ENGINE.—A number of these useful and economical engines to be seen in actual work in town and country. Being free from all danger, they can be used where steam power is totally inadmissible. Exhibition, and every information supplied at 40, Cannon-street, Leicester-square, W.C.

HOLLOWAY'S PILLS AND OINTMENT.

BILIOUSNESS, DYSPEPSIA.—There is no organ in the human body so liable to derangement as the liver. Food, the nature, climate, and anxiety all disorder its action, and render its secretion the bile—more or less depraved, superabundant, or scanty. The first symptoms should receive attention. A pain in the side or top of the shoulders, a harsh cough, and difficulty of breathing, are signs of liver disease which is removed without delay by friction with Holloway's Inestimable Ointment. The Pills should also be taken early. For all diseases of this vital organ, the action of these combined remedies is a specific in checking the over supply of bile, regulating its secretion and giving nervous tone.

PATENT HOLLOW STEAM PACKING.

The great and peculiar advantages of this packing consist in its remaining perfectly elastic, and is so constructed and applied that the pressure of the steam itself makes the joint by entering the packing from the cylinder; thus the many objections to packing previously existing are effectually removed.

Vulcanised India-rubber Sheet Washers, Valves, Springs, Hose, Glazed and Solid Tubing for Gas, Speaking Tubes, Diving Dresses, Gas Bags, Air-proof Goods, or any description of India-rubber articles made to order.

Price list or circular, with full description of packing, to be had of the only Manufacturers and Patentes of Hollow Steam Packing.

FOSTER and WILLIAMS, India-rubber Works, Cowper-street, City-road.

EAST TEMPLE CHAMBERS, WHITE-FRIARS STREET, LONDON, E.C.

THE EVAPORATER SURFACE CONDENSER (PERKINS'S PATENT).

—This simple apparatus, having now been in use for some years, can be strongly recommended as very effective and economical. A vacuum of 26 in. can be readily obtained by evaporation alone, and all the water now required for the ordinary condenser is dispensed with entirely, and pure water is returned to the boiler, thus avoiding all sediment, &c. In non-condensing engines the water is returned to the boilers at a temperature of 212 deg.; and, by the addition of a donkey air-pump, all the advantages of a condensing engine is obtained.

PRIZE MEDALS.

INTERNATIONAL EXHIBITION, CLASS I. AND II.

PATENT PLUMBAGO CRUCIBLES.

The Crucibles manufactured by the **PATENT PLUMBAGO CRUCIBLE COMPANY** are the only kind for which a MEDAL has been AWARDED, and are now used exclusively by the English, Australian, and Indian Mints; the French, Russian, and other Continental Mints; the Royal Arsenal of Woolwich, Brest, and Toulon, &c. &c.; and have been adopted by most of the large Engineers, Brass Founders, and Rollers in this country and abroad. The great superiority of these Melting Pots consists in their capability of melting on an average Forty Pourings of the most difficult metals, and a still greater number of those of an ordinary character, some of them having actually reached the extraordinary number of 96 meltings.

They are unaffected by change of temperature, never crack, and become heated much more rapidly than any other crucibles. In consequence of their great durability the saving of waste is also very considerable.

The Company have recently introduced Crucibles especially adapted for the following purposes, viz.:—**MALLEABLE IRON MELTING**, the average working of which has proved to be about SEVEN DAYS; **STEEL MELTING**, which are found to save NEARLY A TON AND A HALF OF FUEL TO EVERY TON OF STEEL FUSED; and for **ZINC MELTING**, lasting much longer than the ordinary iron pots, and saving the great loss which arises from mixture with iron.

The Patent Plumbago Crucible Company likewise manufacture and import Clay Crucibles, Muffles, Portable Furnaces, &c., Stove Backs, all descriptions of Fire Standing goods, and every requisite for the Assayer and Dentist. For Lists, Testimonials, &c., apply to **THE PATENT PLUMBAGO CRUCIBLE COMPANY, BATTERSEA WORKS LONDON S.W.**

PARNACOTT'S MACHINERY FOR SHAPING AND SHARPENING SAWS.

THIS invention, by Mr. Edward Parnacott, mill sawyer, of Leeds, relates to an arrangement of machinery for shaping and sharpening the teeth of saws by the aid of emery wheels or other rotary cutters. To attain this end, provision is made for the relative adjustment of the saw (straight or circular) and the emery wheel or cutter, so that all the cuts required to complete the saw sharpening operation may be given by the machine.

The saw blade is held in a compound clamp, which slides upon a horizontal table, and this table is mounted on pins, which allow of its being rocked from side to side, that the saw blade may be raised at one end and depressed at the other to suit the angle of cut to be given to the saw teeth. The straight or blade saw is traversed longitudinally past the cutter by means of a hand wheel working a pinion and rack with which the compound clamp is

fitted. The cutter is mounted in a vibrating frame carried by a horizontal turn plate, and its forward movement to reach its work is adjusted by a fixed stop, so that a uniform depth of tooth is ensured. A vertical movement is given to the cutter by means of a screw and hand wheel, which raise and lower the bracket that carries the turnplate. This vertical adjustment determines the angle at which the periphery of the cutter will act upon the saw, and it

thus enables the cutter to make a square or a chamfer cut as desired.

Fig. 1 is a front elevation of the improved saw-sharpening machine; fig. 2, a side elevation, partly in section; fig. 3 is a back elevation, showing the standard table and driving gear; fig. 4 is a partial sectional plan, showing the turntable which carries the cutter frame; and fig. 5 is a plan view of the clamp for holding a blade or web saw, and presenting it to the emery wheel, and fig. 6 is a partial plan view of the table detached; fig. 7 shows, in side elevation, the table fitted with a clamp for holding a circular saw, and presenting it to the action of the emery wheel or cutter; fig. 8 is an end view of the slotted table, showing the bolt and socket for holding the circular saw; and fig. 9 is a plan view, showing the circular saw under the action of the cutting wheel.

A, A, is a standard, carrying at its upper end the rocking table, and is provided with adjustable and fixed brackets for carrying the various working parts of the machine; B is the driving shaft (mounted in two journals fixed on the bottom flange of the standard A, A) carrying the fast and loose belt pulleys C, C, and also a grooved driving pulley C₁, which transmits rotary motion through a band to a grooved pulley E₁ on the end of a short shaft E, carried by a headstock E₁. This headstock slides upon a bracket, D, projecting from the back of the standard A. Upon the fixed bracket is mounted a weighted crank lever E₂, which by pressing against an adjusting screw E₃, connected with the headstock, keeps the driving band at the proper tension. The short shaft E (mounted in headstock E₁) carries two grooved pulleys F, F, for the purpose to be presently explained.

On the front face of standard A the bracket G slides vertically, supported by a vertical screw H, which passes through a nut I, provided with a rim, and resting upon the bottom flange of the hollow casting, so as to be easily turned round. The bracket is held in its proper position by a bolt (fig. 2) fitting into a slot in the standard A. Upon the bracket G is fitted the turntable J, J, in which are cast segment slots for receiving bolts, which by means of thumb-nuts hold it firmly to the bracket. In suitable brackets, forming part of this turntable, are mounted the shafts K, K (fig. 4), to each of which is keyed a guide pulley, K₁, K₁.

On two other projections from the turntable, J, J, is mounted the rocking frame L, which carries at its upper end the cutter shaft L₁, with its driving pulley and emery wheel or other cutter; L₂ is an endless driving band, which, passing round one of the pulleys F, to and under the guide pulleys K₁, and thence over the grooved pulley of the cutting wheel, communicates motion to the cutting wheel.

On the top of the standard A is mounted the rocking table M, carried by the bolts M₁, M₁. A segmental slot is made in the front end of the table to receive a bolt M₂ for holding the table at any required angle. Upon table M is bolted the compound clamp, by which the blade or web saw is presented to the cutting wheel. This compound clamp consists of an adjustable standard O, attached to the table by a nut screwed on to a clamping bolt, the head of which is shaped to slide in the longitudinal groove formed in the face of the table (fig. 3). On the front face of this standard is an L-shaped slide, O₁, which moves over, and is supported by L-shaped guides. The horizontal portion of this slide O₁ forms the under jaw of a clamp, in which the saw blade to be sharpened is placed. Over this jaw is placed a loose jaw, O₂, which when the blade is in place (fig. 2) is screwed down (as shown in fig. 5). At the back of slide O is a rack (1), into the teeth of which a pinion (2) takes. This pinion is keyed to a short axle, supported in the standard O, and carrying at its upper end a hand wheel. A traverse motion is given to the clamp by turning this hand wheel, and thus the teeth of the saw are each in succession brought under the action of the emery or other cutting wheel.

Adjustable stops may be provided on the turntable for limiting the amount of vibration of the cutter frame L, both towards and from the work. A tendency is given to the cutting wheel to leave the work by weighting the cutter frame at its lower end, as shown at figs. 1 and 2; and handles are provided at the upper end of the frame to enable the attendant to bring up the wheel to its work. By means of an adjustable stop it will be obvious that the depth of cut may be accurately determined. The "tension" crank lever, E₂, is forked at one end (shown in detached views, figs. 5*, which represent it in partial side and edge views) and it embraces a collar fitted with pins, which take into slots in the fork. Into the collar fits the end of the screw E₃,

which rests in a bearing in the bracket D, and passes through a tapped lug pendant from the headstock E₁. When the weighted limb of the crank lever drops out of the horizontal line, it may be brought up to position by turning the adjusting screw, and thrusting back the upper limb of the crank lever.

It will now be understood that the machine admits, first, of the saw blade being presented to the cutting wheel at any desired angle from a horizontal line in order to form an inclined cut; second, besides the depth of cut being variable as desired, that any amount of chamfer or undercut may be given to the tooth by simply raising or lowering the cutting wheel frame; and, third, that from the cutter frame being mounted on a rising and falling turntable, the angle of the chamfer cut may be adjusted to suit any inclination of gullet tooth.

When it is required to sharpen circular saws remove the slide O, and substitute for it the arrangement shown at figs. 7 and 8. The bolt, N, is somewhat similar to that which slides in the groove of the table M, and secures the slide O (fig. 2) firmly thereto; but in this case the bolt is provided with suitable socket and nut for gripping the saw, in addition to the clamping nut, which secures the bolt in position on the table, which position is determined according to the diameter of the saw to be sharpened. A rest (P) is provided at the front end of the table for the circular saw, in order to prevent its vibrating under the action of the cutting wheel.

In order to ensure the proper step-by-step motion of the saw (whether straight or circular) past the cutting wheel, adopt any of the contrivances now in use for insuring regularity of feed.

SCREW DRILLSTOCK.

There are many purposes to which our readers will find the annexed drillstock, known as MacDowall's, very applicable. It acts by reciprocating motion, and consists of a rod of the so-called pinion wire. The one end of the wire is bored up to serve as a socket for receiving the drills, the other end is formed into a centre point, and contained within handle or socket, by which the instrument is guided to and pressed into the work. The remainder of the instrument consists of a slider or nut, fitted to the ribs of the pinion wire, and having a handle with a universal joint. Were the grooves of the pinion wire straight like the flutes of a column, the nut

might be slid up and down without giving any motion to the drill, but the wire being twisted to the extent of two or three turns in its length, like a very oblique screw, every ascent or descent of the handle of course causes a circular reciprocating motion of the drillstock, and fulfills the office of the drill bow of the breast drill, or the cross staff of the upright or pump-drill. This instrument does nicely for small holes, but additions have been made by the inventor which much increase its power. First was added a transverse or diametrical arm at the foot, carrying two momentum balls, but these gave inconvenience at starting and stopping suddenly. This defect was remedied by introducing a little catch wheel or ratchet in the nut, by which, as in the Brequet watch key, &c., the catch slips over the teeth of the ratchet wheel in the ascent, and only moves the drill in the descent; thus allowing the fly to act uninterruptedly and impel the drill with continuous motion in the one direction only, and with increased force, and pierces holes of fully twice the diameter of those bored by the simpler drill.

SWEDENBORG.—No. II.

(Continued from page 55.)

ONE of Swedenborg's discoveries about this period (1720-21) was that of the gradual subsidence of the Baltic Sea, which, with his geological observations in the field, says Mr. E. Rich, led him to conclude that deep waters once covered the dry ground. He also explained the translation of the huge boulders which are dropped here and there over the plains. In 1721, at the age of 33, our author visited Holland a second time, to examine the mines and smelting works, and to study the natural sciences; and, besides contributing to the Swedish "Transactions," he published at Amsterdam, "Some Specimens of Works on the Principles of Natural Philosophy, comprising New Attempts to explain the Phenomena of Chemistry and Physics by Geometry;" "Observations and Discoveries respecting Iron and Fire, and particularly respecting the Elemental Nature of Fire, with a new construction of Stoves;" "A new Mechanical Plan of constructing Docks and Dikes;" "A mode of Discovering the Powers of Vessels, by the Application of Mechanical Principles;" "New Rules for Maintaining Heat in Rooms;" "An Elucidation of a Law of Hydrostatics," referred to above; "A new Mechanical Plan of Constructing Docks, whereby Vessels may be repaired in Harbours that are not reached by the Tides;" and "A new Construction of Dams or Moles, for Arresting the Course of Rivers, Torrents, &c." The principle of the hot-air stove, then, was discovered nearly a century and a half ago. In 1722 our author published in Leipzig his "Miscellaneous Observations about Natural Things, especially about Minerals, Iron, and Fire; on the Strata of Mountains; and an Essay on Crystallization." "The beginning of Nature," he says, "is identical with the beginning of Geometry;" he therefore attempted to traverse chemical essence and combination by the fixed truths of Mathematics, and to carry the pure sciences into those which are mixed. From a London magazine of 1830 we quote—"The science of crystallography is of recent origin, and has lately attracted the notice of some very able men. Nearly all simple substances and many of the compounds formed in Nature have regular forms. * * The basis of the science is an analysis of the various figures, so that they may be reduced to a very few simple forms, which, by addition one to the other, may make all existing varieties. This subject is mentioned in a work on Chemical Philosophy published in Paris, by M. Dumas, a gentleman of much and deserved celebrity. M. Dumas distinctly ascribes to Swedenborg the modern origin of the science of crystallography. He says, 'It is then to him we are indebted for the first idea of making cubes, tetraeders, pyramids, and the different crystalline forms, by grouping the spheres; and it is an idea which has since been renewed by several distinguished men.' The subject of the central fire of the earth has brought forth so many papers and speculations, especially, it may be remembered, the celebrated contributions to the *Times*, respecting the varying depths of fire-strata, that we cannot omit a short extract from the "Miscellaneous Observations," in which our author says—"I admit that it is undeniable that a certain subterranean fire really exists, that is to say, that in some parts of the earth's crust a degree of heat is perceptible, which causes thermal springs, volcanic eruptions, and many other phenomena; but whether this heat proceeds from the earth's centre, and whether there be a cavity full of fire, or an igneous void—this is to the last degree questionable, and for the following reasons: 1. Because fire cannot live, unless it be enclosed in hard bodies, as in carbonaceous matter already mentioned as shut up with the fire in a furnace. 2. But if the furnace contain no solid fuel, although it be full of flames, no sooner is it closed than the fire dies out, lasting in fact no longer than the heat remains in the hard bodies. Consequently fire cannot be kept in a cavity unless solid substances be present. If, therefore, there be any heat in the centre (supposing a central vacuum to exist), such heat must come from the substances of the crust, instead of the crustal heat proceeding from the centre. 3. Hence we may conclude that heat exists in many parts of the earth's crust, and not in others." The subjects of Light, Sight, and Sound, are beautifully treated, and the reader of works issued in the present day will be surprised to find in the researches of Swedenborg much of what is now accepted, and more of what will yet become widely known. In the preface to this treatise on the principles of Chemistry he observes that physics and chemistry are essentially geometrical, and that the variety of experiments in both can be nothing more than variety in

position, figure, weight, and motion of the particles of bodies, consequently, that the facts of these sciences must indicate the geometrical forms and mechanical motions of the elements of substances. He did not doubt that chemistry, in its inmost, was amenable to the rules of mechanics, and that there was nothing necessarily mysterious in it. His theory is that roundness is the form adapted to motion; that the particles of fluids, and specifically of water, are round hollow spherules, with a subtle matter, identical with ether, or caloric, in their interiors and interstices (which, by the way, is now accepted by some who write on the generation of steam); that the crustal portion of each particle is formed of lesser particles, and so on; water being, in this way, the sixth dimension, or the result of the sixth grouping of the particles; that the interstices of the fluids furnish the original mould of the solids—and so on.

At this time in (1724) he received an invitation to accept the Professorship of pure mechanics at the University of Upsala, which, however, he declined. In 1729 he became a member of the Royal Academy of Sciences at Stockholm, and was a most active member, communicating all he thought would be of interest to his fellow men which came under his physical and mental observation. As to the keeping of things—discoveries and thoughts,—secret, hear him speak: "There are persons who love to hold their knowledge for themselves alone * * * How low and drooping their aspirations, and how ungenerous their air! For surely no man has a right to hold his knowledge for himself alone, but rather for others, and for the whole learned world. I grant, indeed, that such characters perhaps possess secrets of some importance which they have got for a small price from those who make all knowledge an article of sale, and whose venal information a few coins will purchase. But why, then, should such secrets be grudged to the public?—why withheld from this enlightened age? Whatever is worthy to be known should be by all means brought to the great and general market of the world. The rights of civilized man convince us of this; the natural function of the individual, equally with the laws of the republic of letters, attests and enforces it. In short, unless we all contribute to the best of our power to make the arts and sciences flourish more and more, in order that eventually they may arrive at that goal which has been the desire of all former ages,—unless we do this, we can neither grow happier nor wiser with time."* I fancy if the recommendation embodied herein were carried out, the Patent Agents generally would find their occupation gone. The paragraph is herewith made a present of to the advocates against Patent Rights.

In May, 1733, he went "abroad" for the third time, for the purpose of acquiring certain knowledge necessary to the successful development of his great work (which he had long been labouring at) in three folio volumes, of 500 pages each—entitled "Philosophical and Mineral Works." Though there are three distinct works, they were all published together, and spoken of by our author as one. The first volume is called "The Principia, or the First Principles of Natural Things," and in it the author attempts to arrive at the cause, or origin, of the universe, by modes of inquiry peculiar to himself. He takes the position, that Nature, in all her operations, is governed by one and the same general law, and is always consistent with herself: hence, he says, there is necessity in explaining her hidden recesses to multiply experiments by observation. The means leading to true philosophy he represents as threefold. 1. A knowledge of facts, or experimental observation—Experience. 2. Orderly arrangement of these facts, phenomena, or effects—Geometry or Rational Philosophy. 3. Analyzing, comparing, and combining these facts after they have been reduced to order—Faculty of Reasoning. Among other positions, he takes this—proved by modern science—that "it is possible that many things of opposite natures, may exist from the same first cause: as fire and water, and air, which absorbs them both." It may here be stated that the whole expense of the production of this work was borne by the then Duke of Brunswick, at whose Court Swedenborg was always a welcome and an honoured guest. Its practical value has not always failed of recognition. The authors of the "Description des Arts et Metiers" translated a portion and inserted it in their collection, and Dr. Cromwell Mortimer, the then Secretary of our Royal Society, alluded to it in the translation of Cramer's "Elements of the Art of Assaying Metal," as "a magnificent and laborious work."

(To be continued.)

*Preface to the Treatise on Iron in "Mineral Kingdom," English Edition of the Principia, vol. 2 p. 371. (London: Alvey, Bloomsbury-street.)

ANSWERS TO CORRESPONDENTS.

G. H. MICHOLLAND will greatly favour us by forwarding another drawing of his furnace bar.

C. HAATCH.—Favour us with another sketch. The printers have lost or mislaid the one enclosed in your letter of the 19th.

H. HURST.—Will you kindly forward, another drawing and description.

F. ALLEN (Ayrshire).—Received; but cannot undertake to engrave.

WILLIAM MALTRY.—We have forgotten the number. Write to the office of the journal, and you will receive the required information.

G. G.—Received.

ALEX. M'DOWAN.—We should advise our correspondent to join some scientific institute or society in the town, and to attend all the lectures that he conveniently can. Let him also persevere in the study of sound writers.

J. H. W. G.—Yes, at an early date.

CHARLES NEWCOME.—We shall be glad to look over your receipts.

VELOCIPED.—Engravings will shortly appear.

H. HUXLEY is thanked, but we cannot engrave from the drawings forwarded. He must send others more correct.

S. B. (Ipswich).—Received, with thanks. It has taken you a long time to make the experiment. The directions were copied from a first-class publication. We are sorry, for your own sake, at your determination.

PHILOS.—Send to Eppingham Wilson, bookseller, Royal Exchange, with a stamped envelope—you will get an answer by return of post. Or the same to Routledge, Broadway, Ludgate-hill.

X. Y. Z. (Chester-le-Street).—Will be attended to.

J. W. J.—If you will inquire at Holtzapffel's, in Long-acre, or Sporn's, in Bucklersbury, they will give you a catalogue of good works to select from.

SERGE-MAJOR EAST (Putney).—Why not place yourself in communication with the gentleman?

THOS. GREEN (Liverpool).—We really do not understand what you require. We remember looking at a drawing of a coal-cutting machine, and giving an opinion of it in, we think, the number following.

DANIEL MCCANE (Glasgow).—Our best thanks for your sensible, manly, workmanlike letter. In this column, last week, you will find an answer to one of your queries. Quitta-percha will do for your second.

GEO. RICE.—Sorry we cannot oblige you. The patentee would have to be written to; or it might be had through a patent agent, who does business for Americans in this country. Try Haseltine, Chancery-lane.

R. W. (Asbestos).—Steep the wood in lukewarm water with a little alum, for two or three days, then put a handful of logwood, cut small, into a pint of water, and boil it down to less than half; add a very little indigo. Spread a little of this liquid on the wood, dry, give another coat; dry, another coat. Then boil verdigris in its own vinegar, and spread on the wood. When dry, rub with oiled chamols leather.—1½ oz. shellac, ¼ oz. each gums mastic and sandarac, spirits of wine 20 oz. Dissolve gum first in spirit, lastly shellac; put on two or three coats; polish with Tripoli and water, and finish with suet and flour, rubbing to a good polish. You can buy the varnish.

W. HADLEY.—The first has had a slight refining treatment, the latter has lost part of its property in the furnace, and has to be re-melted with other iron containing a superabundance of what the burnt iron has lost.

ALB. MAGNUS.—Printers simply stretch theirs, and damp it while stretched—that is all.

R. M. (Harwich).—Boil up a lye (in a copper) of soda, ash, lime, and water. Then coal, and carbonate of lime is deposited; next draw off the lye, and add it to the tallow, fat, or oil, in the proportion of 150 gallons of lye to a ton of fat. Then set the steam under it again, adding stronger lye until there is no greasy peel. Common salt is added to separate the glycerine and other impurities derived from the grease. These are drawn off, stronger lyes added, until the whole soap separates. It is then transferred to cooling frames, and when hard is cut into bars (see query number 2 in proper place).

*We have to ask our correspondents to sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them by the thousand; the same with "Well-Wisher," &c. If they don't like to see their own names paraded, use those of an ancient or any other man.

Several letters remain over till next week for answer.

LETTERS applying for information to be furnished by post cannot be attended to.

Correspondents are requested to keep copies of their drawings and manuscripts, as the Editor cannot undertake to return such as may be rejected.

A PIECE of amber weighing 13lb. was valued at Constantinople at 30,000 dollars.

DR. BACONIO, of Milan, has shown that a few alternations of slices of beetroot and wood of the walnut tree are capable of setting free sufficient electricity to excite convulsions in a frog, when conveyed to its muscles by means of a conductor formed of a leaf of scurvy-grass.

THE intervals or distances of the waves of red light from one another, in the succession which they follow one another to produce extreme red, are such that there are 37,640 to an inch; of yellow, 42,550; of green, 47,460; blue, 52,910; extreme violet, 59,750; mixed or white light waves, 44,440.

NOTICE TO ADVERTISERS.

ADVERTISERS in this journal are respectfully informed that the Collector from the office, 162, Fleet-street, will call upon them for a settlement of the amounts due for the insertion of advertisements. The Collector will in every instance hand in a printed receipt for the sum paid to him. Advertisers are particularly cautioned against paying money without receiving the printed receipt.

THE ENGLISH MECHANIC!

Just Ready, and now Publishing, the
FIRST VOLUME
of
THE ENGLISH MECHANIC,
A Record of Mechanical Invention, Scientific, and
Industrial Progress.

UPWARDS OF ONE HUNDRED
ILLUSTRATIONS.

Handsomely bound, only 4s. 6d.; post free, 5s.

GEORGE MADDICK, 162, FLEET-STREET, LONDON,
and all Booksellers.

THE ENGLISH MECHANIC.

Every Tuesday, One Penny. Monthly Parts, 5d.

Now Publishing, complete, the First Volume.

* * Title Page and Index, One Penny. Cases for
binding, One Shilling and Sixpence.

It is solicited that all back Numbers be ordered at
once.

All the early Numbers have been reprinted. It
is therefore necessary that sets be made up at once,
as there will be no further reprints owing to the
great expense they entail.

162, FLEET-STREET, LONDON, and all Booksellers.

TO ADVERTISERS AND CORRESPONDENTS.

* * In future all Advertisements and Communica-
tions for the Editor to be sent to

162, FLEET-STREET.

OUR MONTHLY PARTS.

Part 7 of THE ENGLISH MECHANIC, in coloured
wrapper, is now ready.

Price 5d. only! Post free, 7d.

All back Nos. have been reprinted, and can be had
direct from our Office, or through any bookseller.

TO ADVERTISERS.

As the ENGLISH MECHANIC addresses itself to the largest
and most intelligent portion of the community, and is
the only Paper of the kind established, it offers unusual
advantages as an advertising medium.

THE CUTLERY TRADE OF SHEFFIELD.

THE Commissioners appointed by Government to
visit our manufacturing centres—including
Sheffield—have made out an apparently sad case in-
deed, have presented as horrifying details in con-
nection with some of the trades as might be
supposed to have existed about the time of Peterloo,
when working-men were generally looked upon by
those above them as simple perambulating tools,
and who were indeed in very many cases but little

removed from the beasts. The cutlers of Sheffield have been singled out by the Press as deserving of special protection by the Legislature: their term of life was set down at one score year and ten, they were designated a race of prematurely old deformed cripples, who, did they reach the old age of thirty-six, had out of that time been working thirty, according to usual computation—according to comparison of working hours, 45 years—that is, allowing 6 hours or thereabouts for sleep and leisure, the remainder for work. But it will have occurred to many that Sheffield is not full of cripples, so as to give correctness to the picture drawn in the Parliamentary Blue Books; as also it will to some, that in various shops in the cutlery town there are now at work three generations of cutlers, among whom there is not one cripple. There is no denying, however, that there does exist a great deal of misery, want, and depravity, and that the death-rate is very high—neither is it, that much of this is brought about by the workmen themselves, and a certain class of masters who take advantage of the criminal conduct of their men to "keep their noses at the grindstone." We will take the case as stated by one of themselves, and leave the reader to judge between that made out by the Commissioners and the thing as it exists. The workman goes into the warehouse on Monday perhaps, gets a job out, and takes it into the shop; but instead of starting on it at once, he starts talking round with his shop-mates, one of whom, let us say, has got a "tip" on what is known in sporting circles as a "handicap," and as that gentleman considers his "tip" as a certainty, his mates and he go off and "lay the odds," or whatever it is called, with the money that should be laid out on files. The shop sees the man no more till Tuesday, and then he is not in order for work, so, as it is market day, off he sets for a turn among the greens and potatoes to waken him up a bit; but the afternoon finds him where he got in liquor on the previous night, with his shirt sleeves turned up, hard at work among dominoes. Of course before night what was left of money is gone, and he plays and drinks on—on tick. Thus the first two days are gone. On Wednesday morning he begins what is now a scuffle instead of work. Of course he has not the proper number or sort of files to work with, and work that he ought to file he does on the rough emery glazer, and by-and-by fills the shop with bone, steel, and black buffalo dust, or pearl dust. With all this "scuffling"—and assistance to disease—he cannot earn a week's wages, so he "writes on account," or, as it is termed, has a lot of "sours" put down, to rub off the Tuesday's score. A week or two further on his "sours" are so heavy that it takes him a week to sweeten them, and thus has no wages on that Saturday night. Debt is contracted on every hand; and the class represented by this man are never one penny before a beggar; their children they never think of sending to school, but put them to the trade as soon as they are able to do anything to make up for their own shortcomings. As a matter of course, the "masters" who employ such "men" have few scruples remaining—"like master like man," and the poor dolts are taken advantage of at every turn. This is true, more especially of a lot among the spring knife cutters, who have the shadow of a union, and if its secretary wouldn't mind telling his experience, he could tell of want of principle and manliness, of stupidity, and of degrading sensuality. As for the crooked legs, arms, and backs, that might have been true when the leg frame was in vogue; there is very little truth attachable to the statement now. As for the price paid for the work done, here more than anywhere else it depends on the men. Were they sober, honest, and industrious as a rule, they would easily get sufficient to enable them to keep themselves and families decently and respectably, and to send their children to school. What Government should do, is not to allow a girl in the trade before she has reached 12 years of age, or a boy till he has turned 11 years; to amend the parish school system and enforce the sending of children to school. If the difference were not all seen in this generation, it would in the next; and that is grand legislation which looks also to benefit in the future. Wherever in Sheffield the cutlers are steady and good workmen, they seem to get along pretty well: they don't seem to die off at thirty, forty, or fifty; neither are they deformed and cripples. And it is to one of these respectable mechanics we are indebted for the above necessary corrections on the report of the Factory Commissioners, which report, so far as it relates to a part only of this same cutlery business, is correct—no further.—F. S.

GAUGES FOR WIRE AND SHEET METAL.

WE have at different times been solicited to give a table with explanatory notes of the values of gauges for wire and sheet metal in general use, expressed in decimal parts of the inch, and in pounds weight and decimal parts of a pound for plates. The delay in publishing this has been caused chiefly by waiting to see if such a thing would be of use to any number of our readers: finding that it is so, we give it, as follows:—

Weight of Plate,	1. Birmingham Gauge for Wire and Sheet Iron and Steel.	2. Birmingham Gauge for Sheet Metals, Brass, Gold, Silver, &c.	3. Lancashire Gauge for round Steel Wire, and also for Pinion Wire.					
	lbs.	Mark	Size	Mark	Size	Mark	Size	Mark
18.16	0000	454	1	004	80	013	40	096
17.00	000	425	2	005	79	014	39	098

.16	36	004			41	095	1	227

This series of measures have no relation to one another—thus, the numbers 10 of the table are different and undefined quantities, neither aliquot nor direct fractional parts of an inch, as the No. 10 notches are generally .137, .024, and .190 of an inch wide.

The approximate measures of any one of these three series may be moderately familiar to those in the habit of using either one, but those persons will very likely know as little of the other two as the generality of individuals—to whom the whole are both vague and ill-defined, because their nomenclatures have no relation to the standard foot and inch.

The second column of the table (21) refers to the gauge used for most kinds of wire, and for brevity is called the "wire gauge," though it is known by three other names. It is the most common of the three principal kinds, and is employed also for brass and other wires, for black steel wire, sheet iron, sheet steel, and various other materials, and also for screws for joiners' use, &c. The largest notch is marked 0000, and measures 454-1000ths of an inch, or nearly 4½ tenths of an inch: the smallest notch, marked 36, measures 4-1000ths, or the 1-250th part of an inch. Though this gauge seems to possess but 40 sizes, 60 are made, as intermediate sizes are added. Thus the sizes of wire drawn for manufacturing needles correspond with some of the ordinary wire sizes, but the numbers are different—

Needle wires Nos. 6, 7, 8, 9, 10, 11, 12, 14, 16, 18, 20.
—Birmingham wire Gauge } 28, 26, 25, 24, 24, 23, 22, 21, 20, 19.

The number 6, music wire, measures about the 1-55th part of an inch in diameter, and No. 20, the thickest, about 1-25th of an inch. The manufac-

turers of the patent screws made from iron wire for joiners' use also give the intervals of the wire gauge a new system of numbers. Thus, the left-hand column of the following table show the Nos. of the screws, the right-hand that of the wires from which they are made:—

No. of the Screws.	No. of the Gauge.	No. of the Screws.	No. of the Gauge.	No. of the Screws.	No. of the Gauge.
25	0000	12	4	5	11
23	000	11	5	4	12
22	00	10	6	3	13
21	0	9	7	2	14
17	1	8	8	1	15
16	2	7	9	0	16
14	3	6	10	00	17
				000	18

Other examples of conversions might be given, but their only use would be to show further the existing irregularity.

(To be continued.)

LETTERS TO THE EDITOR

[We do not hold ourselves responsible for the opinions of our correspondents.]

ANGLE OF LATHE CENTRES.

By neglecting to make a correction, forwarded to us by "Kilmarnock" himself, our kind correspondents have had a great deal of unnecessary trouble and vexation. "Kilmarnock" had been misled, in the first place, by his marked gauge, the figures on which had been wrongly engraved. We discovered the error in time for that correction, which in the hurry of going to press was overlooked by us.

RADIUS OF A CURVE.

Sir,—In reply to "Hand Chisel." Multiply the height of the side by the greater diameter, and divide by the difference between the two diameters, and the product is the length of radius required. Example:—Height of side 18in., greater diameter 36in., lesser diameter 8in., difference 28in. Circumference $36 \times 3.1416 = 113.1$. $18 \times 36 \div 28 = 23\frac{1}{2}$ 1-7in. Set the compasses to 23 1-7in., draw a curve for top of pattern, then set the compasses 18in., less, that is 5 1-7in., and from same centre draw the curve for bottom of pattern, and from the centre draw a straight line to one end of the large curve—then from this line mark off the circumference 113in. upon the large curve, from this point draw another straight line to the centre, and you have the full size pattern required. If required in 8 equal sized pieces, mark off 14 the circumference 37 1/2in. upon the large curve. Allowance must be made for seams and wires. If 18in. is the perpendicular height, draw a section full size of the vessel required, and measure the height of side.

F. B. C.

OUR SUBSCRIBERS' NOTES AND QUERRIES.

POLISHING PEARL.—Can any one tell me how to do this?—T. W.—(In answer to query 2, respecting dipping. After the work has been fitted, anneal it over the fire to red heat, and let the cooling be gradual. This heating removes dirt and grease. If the work is to be soldered, anneal before soldering, and after soldering boil in a lye of pearlash. Next pickle in dilute aquafortis—the old bath containing a small quantity of copper in solution is preferred. Let the work remain in the bath for an hour or two, according to the strength of the bath. Next scour bright with sand and water, with a scrubbing brush. Then place in clean water, waiting for the dip. This bath consists of pure nitrous acid, a sufficient quantity of which is poured into an earthen vessel to cover the work as far as required. If the whole article is not to be dipped, use brass plyers to handle it with. The bath being ready, whip the work out of the water, give it a shake, and dip it into the aquafortis for an instant only. Then plunge it into clean water to remove the acid, then immediately into hot water, next shove it rapidly into sawdust and rub until quite dry. Should the work not be bright enough, repeat the process, taking care to make the soaking in water and drying with sawdust a rapid process. The work is then burnished as rapidly as possible, where required, and lacquered as soon as possible.)

SEASONING PLAINTEAK.—How can I do this, or with aycamore to prevent splitting—for rollers, 36in. long, 8in. diameter?—J. D.

TO MAKE A HOIST.—The simplest way for taking dishes from one flat to another.—J. DAVIS.

HEATING.—The best way to heat a church or hall—if with water, best shape of boiler, size of pipes, &c. Also best cement for joining the pipes.—J. D. (Glasgow.)

CEMENT.—Wanted the best, for hot-water pipes?—SANDHILL.

FIRST SAW.—Will any correspondent oblige me with the drawing of a first saw for inlaid cabinet work?—J. W. (For the other send to Spon, and he will forward you a catalogue of his works, free.)

GILDING.—What is the difference between mercurial, water, and fire gilding?—G. L. A.

BLUING BRASS.—How is the blue colour put on the polished surface of such articles as pointers?—J. NIXON.

DIFFERENTIAL PISTON.—Can any one oblige me with a sketch of a differential piston as applied to steam hammer by the Messrs. Bramwell and Baggs in 1853?—LOCOMOTIVE.

SEPARATING LEAD FROM SOLDER.—How can I do this, to leave the lead pure?—J. BAGGS.

DYED GAS!—Can any one tell me how to produce gases, giving different colours?—**JOHN TURNER.**

CAPSULING MACHINES!—Where can I purchase first-rate capsuling machines?—**W. W.**

HEATING.—Can any one who has used it tell me how Perkins's system of heating greenhouses answers?—**OLD SUB-SOBER.**

APPLYING STEAM.—Why should not steam be applied directly to shearing plates, as well as to driving the steam hammer? Also, what is the average proportion which a cylinder bears to the boiler?—**R. M. M.**

PRUSSIAN BLUE PULP.—How can I make Prussian blue pulp, at once, on the fire, so it will be sweet and a good bronze?—**R. M.**

COLLECTING ELECTRICITY.—Will this do, in place of Leyden jars? Two layers of sheet caoutchouc alternated with 3 layers of tinfoil and rolled up, but so arranged that one layer of foil could be connected to the machine and the other with the earth.—**HY. GORNALL.**

GRADUATING.—How can I get two circles of 12 inches in diameter finely graduated?—**ASTRONOMICUS.**

THE MICROSCOPE.—How can I cut the very thin glass on which microscopic objects are mounted? They are perfectly round and as thin as a wafer?—**C. SMART.**

HYDRATE OF ALUMINA.—J. R. will be obliged to J. H. M. if he would inform him how to make hydrate of alumina, as he cannot obtain it at any of the druggists in the town.

SLIDGE HAMMER FORCE.—Can you inform me as to what is the equivalent in tons pressure, to the effect of a blow of a sledge hammer given by a man of ordinary strength, the sledge hammer weighing 20lbs.?—**R. O. S.**

WATERPROOF.—How can I make a good waterproof that will dry quick, for fishing stockings of a cotton material?—**F. A.**

INJECTION PIPE.—What is the size of injection pipes required for engine indicating 130 horse-power, diameter of air pump 23 inches length of stroke 15 inches, 50 strokes per minute?—**J. SEDDON.**

PARALLEL MOTION.—How can I set a parallel motion?—**FITTER.**

OBJECT GLASSES.

Sir,—In reply to Mr. T. Edmonds, in No. 26, I beg to say that the focal length of the object glass which he requires is about 16 inches. The image should be formed by it just in front of the 4" lens of the eye piece, and, as the latter is 6 inches long, allowing an inch for adjustment, 23-6-1 = 16.

The enquiry of Swede, in No. 27, is rather vague; but he will find the fullest account of grinding and polishing lenses, in Vol. 3 of Holtzapffel's "Turning and Mechanical Manipulation," p.p. 1262 to 1274; also, less detailed ones in "Herschel on the Telescope" (price, 3s. 6d., A. & C. Black) and "Pritchard on Optical Instruments," one of the Useful Knowledge Society's eighteenpenny books, published, I think, by Baldwin. These last two works contain also a table and formulae for computing the curves of object glasses.

No amateur can possibly produce the proper glass "in a raw state." It can only be obtained of the Messrs. Chance and Co. of Birmingham. **AN AMATEUR TURNER.**

CORRECTION, &c.

Sir,—In my letter on clocks published in No. 30, "Robbin" should be "Robin."

Young Mechanic can obtain a small book from Aston, 25, Old Compton-street, Soho, which will tell him all about the slide rule.

Crank turning: In I. M.'s diagram, the left side of the crank should be stayed as well as the right. **W. J. F.**

Sir,—In reply to Tyro, No. 30, there is no difference in the power of screws of various number of threads in diameter, so long as the pitch remains the same. There is a difference in the amount of power they absorb. **PLIAS.**

ECCENTRIC SHEAVE.

Sir,—There is a slight mistake in the explanation of the diagram of the eccentric sheave I sent you. The words "lever advance" are used instead of "linear advance." The letter T should have been I. **JAMES MORRISON.**

FUR IN KETTLES, &c.

Sir,—In reply to T. G. Moreland. The incrustation deposited on metallic surfaces by precipitation of the earthy impurities in the water speedily shells off when potatoes are boiled for a few hours in the vessel. **F. G. M.**

HOW TO BLEACH TALLOW AND RESIN.

Sir,—These gentlemen are trespassing on dangerous ground, and if badly in want of the information asked for should purchase at the Patent Office specifications of the several inventions relating to these subjects, not forgetting while searching the old adage that "Honesty is the best policy," and that "frustrators" are liable to legal penalties for infringement. **F. G. M.**

WORKS ON TURNERY.

Sir,—Referring to the excellent list of works on Turnery in your journal, I find that Bergeron's "Manuel du Tourneur" is dropped out of Rover's catalogue of December last. It is not in the series "Encyclopedie-Rover," but in another, entitled "Industrie Art, et Metiers," price about £2 10s. But I think Williams and Norgate, of 14, Henrietta-street, Covent-garden, continue to supply it. If I understand the observations of your contributors, it is not superseded by the work of Valcourt in the "Encyclopedie-Rover." The title of this latter in the catalogue of the Encyclopedie-Rover is "Tourneur, au Trait complet et simplifie de cet Art, d'apres les renseignements de plusieurs. Tourneurs de la Capitale: par M. de Valcourt. 2 Vol., avec un Atlas en 4, de 29 planches, 12 francs." This differs somewhat from the title given in your contributor's list. Is it the same work? Its price does not indicate comprehensiveness, and it may be a sufficient guide to the practice of plain turning. **BETA.**

WORKS ON TURNERY.

With respect to a recent suggestion in our columns of a compilation from existing standard books on the subject, to supply the incompleteness of the late Mr. Charles Holtzapffel's great work, it is understood that the present representative of a name so dear to all mechanicians, professional and amateur, is in possession of the ample materials amassed by his honoured father, for the completion of his work; and, moreover, that he is abundantly qualified for the task of reducing these into shape for publication, in the same admirably simple, yet lucid style, that characterises the volumes already published, and also to bring down the work to the latest extensions and improvements in the art. It is earnestly to be desired that Mr. John I. Holtzapffel might, even amidst the pressing exigencies of extensive and engrossing business avocations, spare as much of his time as to complete a task that may be said to devolve on him by inheritance. No doubt, scientific works of this high class, involving as they do vast research, labour, and cost, are rarely, if ever, remunerative to the author; so that it would necessarily be with Mr. Holtzapffel a "labour of love"; but he has the inducement of knowing that, in accomplishing it, he would bestow an inestimable benefit on a country so deeply interested in the science and art of mechanical engineering as this is, and at the same time fulfil what the public will be apt to look upon as a trust imposed upon him by his position, as the representative of a family which, for three generations, has been so eminent in the annals of the profession. **R.**

OIL FOR CLOCKS.

Sir,—If E. Feather will get a 2-ounce bottle full of the best sweet oil, and put into it about half an ounce of lead, and let it stand for a few days before using it, he will have a very good oil for clocks. I had the mode recommended to me as the best and easiest way to purify it, and I have tried it and it answers well. The lead should be near the length of the bottle, and may remain in until the oil is used up. **R. F. W.**

Sir,—Having broke a first-rate whetstone, I should be much obliged to any of my fellow workmen who could tell me of a cement to join together that would not affect the pool in passing over it. **R. F. W.**

Sir,—In answer to Perambulator, coach paint is prepared much the same as colours used by house-painters. With the exception of the better colours such as blue, lakes, &c., those are generally prepared for use in varnish. There are varnishes prepared for coach painters' use, suitable for the various purposes of coach painting. If Perambulator will send his address to your magazine, I should be very willing to call on him and give him any information on the subject he may desire. **COACH PAINTER.**

PENTAGRAPH.

Sir,—In a former number an enquiry is made for a description of Taylor's pentagraph machine for engraving cylinders. The best description is contained in Taylor's specification, which may be met with at the Patent Office. The date is 1848; but I forget further particulars. Improvements have been made and patented, 1862, No. 2307, by the writer. **H. E.**

MAHOGANY DYE.

Sir,—In answer to Z. Y. X., he can make a very good mahogany dye by boiling logwood, and giving the work two or three coats, and in the last coat put a small quantity of American potash; if too much potash, the work will be turned very dark. **J. W.**

BAGATELLE CUE TIPS.

Sir,—In answer to J. W. Moore, I have seen in shops where bagatelles are made a white leather about one-eighth of an inch thick put on with glue. First, glue the end of the cue, and leave it dry; then give it a second coating, and put the leather on. The first coat prevents the second going into the end grain of the cue. **J. W.**

[Send on your tracing and description, and we will do the best we can.]

STEAM PRESSURE.

Sir,—In answer to J. E. M., the pressure of steam upon each piston will be the same; for the effective surface of a piston cannot be greater or less than the area of the cylinder—that is, if it fits, of course. The one marked F would perhaps be the least effective, in consequence of the increased friction upon the one side of the cylinder by the pressure of the steam. **F. H. F.**

STEAM HAMMER.

Sir,—In reply to T. Y., the amount of work done by the steam hammer in the case put, would be equal to 929 6 foot pounds; but there is no means of rendering this comparable with the effect produced by dead weight, since, unless the dead weight, moved (however infinitesimal) the space might be through which the motion occurred) no work could be done by it.

A strange error has crept into the concluding portion of Asprant's solution of the difficulties of R. E. Mellor, it being stated that the formula given being applied to the case in point "gives 07 inches as bursting power."

W. TONKES.

RAISING A COLUMN OF WATER.

Sir,—As Fred wants to know of some mechanical means to raise a column of water in a three-quarter inch pipe to the 20 yards:—

Let him get a small force pump—or two, if he thinks fit—connected on a crank shaft, the one opposite the other, and let him key a small water-wheel on to the end of the crank shaft, and place it so that the water will fall upon it, and I think it will answer his purpose. **JAMES MORRISON.**

MAHOGANY DYE.

Sir,—Z. Y. X., No. 29, will find the following a good mahogany dye:—
Boil equal parts of madder and Brazil wood, add a little log wood, brush the work over while hot; when dry, paper the roughness down with fine glass paper, and if the colour is not deep enough, add a little dragon's blood with the polish. **T. W.**

FURNACE BARS.

Sir,—I thank Mr. T. Jackson for his information about furnace bars. Will he be kind enough to give a more clear description of his bar, as to the thickness and so on, the small figures, &c., not being distinct, and sketch? **H. PRITCHARD.**

FALLING BODIES.

Sir,—With regard to the question of falling bodies put by J. L., the attraction of gravitation, as a matter of comparison, has nothing to do with either the density or specific gravity of various bodies. However large the mass, or whatever the nature of its constituent particles may be, the earth attracts each particle alike, and with the same degree of force; hence, each would approach the centre of attraction with the same velocity, whether free from, or bound in union with, any number of similar atoms. The real difficulty of J. L. lies in the obverse of attraction, viz., an opposing force to its exertion, then the question of mass becomes one of serious consideration. Take two bodies, one of a single atom, the other one million atoms; to attract the first a force represented by one only would be required; but the force of one million times as great must be exerted before motion could be produced in the other, and, since this force is distributed over one million atoms, why should we look for an increase of velocity? We have no reason to do so—we do it not, and we never find ourselves disappointed; but were we to place the same resistance to this force to oppose the motion of the million particles, that would effectually arrest the single one, then we should find that though there was no greater velocity, there was still an exertion of one million times in active operation. **W. TONKES.**

TO SAVE VARNISH.

Sir,—The glue also recommended by New Leeds, and Amateur Turner, although it fills up the pores, obscures the surface. The following composition should therefore be used preferentially, as it fetches up and causes the natural grain of the wood to bear out and indelibly strikes in any required tone of stain applied for increasing the colour and general effect of the work. The recipe is gum shellac, 1lb; methylated finish, 1 quart. When the gum is thoroughly dissolved by the aid of gentle heat and frequent shaking, dilute with the spirit to required consistency for use. This simple and inexpensive admixture is from its adhesiveness and durability of peculiar value in a factory for coating patterns, particularly those for bushes of journals, pinions or wheels of low pitch in which the fibres of the mahogany or pine must be presented endwise to the surface, therefore the edges are apt to be broken away; in all such cases the application of one or two coats to the work while new will render it impervious to damp—capable of withstanding a higher than ordinary degree of temperature, and by imparting uniform smoothness of surface necessarily expedite the operation of moulding. **F. G. M.**

BOILER CONSTRUCTION.

Sir,—A. Nelson, in your number for October 13, proposes to have his boiler made of two feet lengths, each length composed of four pieces, the longitudinal joints to be rivetted with strips, the transverse joints to be encircled by a hoop. This description of boiler would be a very heavy one, and it would only add strength to the boiler equal to the area of cross section of hoop at weakest part; but it would not possess any of the advantages claimed for it by your correspondent.

Two thicknesses of iron in a boiler offer a great impediment to the transmission of heat—in fact, the outer plate will become hot, and the rivet heads more seriously heated still, and thereby cease to offer material resistance to the pressure of steam; or should they withstand the pressure, would require repairs continually owing to the leakage, &c., caused by the action of the flame, making more expensive still a very expensive boiler. The strips inside (I speak of externally fired boilers) would offer every facility for furrowing in a greater degree than the common single rivetted joint of the old boiler, and would be less effective for generating steam.

These objections apply equally to this system when applied to the construction of flues, namely: the impediment to the transmission of heat, the certainty of becoming overheated, and consequent loss of strength, and liability to furrowing.

Allow me to suggest that by having his plates 3 feet broad or more, and sufficient length to form a ring, the required size of boiler, and welding the edges together, (which by a proper system of welding would be about equal to strength of plate) then these rings rivetted together transversely would form a strong, neat, durable shell, having no rivetted joints but the transverse ones.

Then as the weakest part of a boiler is its longitudinal seams, the strength of the boiler would be increased from 34,000lbs square inch to 50,000. This speaks for itself.

Then I will conclude in the words of your correspondent slightly altered: 1, there are no weakened joints; 2, the boiler being a true circle, the strain is equal; 3, there are no longitudinal seams under water; 4, the edges of the plates not being exposed, no space for the chemicals to rest, &c.

P.S. Will you have the kindness to correct an error in answer to R. E. Mellor, of this week. The "07 inches as bursting power," should read "07 inches, equal to a bursting pressure of 490lbs square inch."

H.M.S. TERPSICHOE, AS DAMAGED BY THE AMERICAN TORPEDOES.

Two illustrations of the very striking experiments with Mr. Beardalee's submarine torpedoes, or explosive shells, exhibited on Wednesday, the 4th inst., in the River Medway, before the Duke of Somerset and other Lords of the Admiralty, were given in a recent number of *The Illustrated London News*. By favour of the naval authorities, we are now enabled to give a reduced copy of the official drawings, made for their information by Mr. P. Thornton, Master Shipwright of Chatham Dockyard, showing the exact amount of damage that was inflicted upon the hull of the old 18-gun frigate *Terpsichore* by the explosion of the two 75-pounders, of which only one was so placed that its effect could reach the vessel.

The Engraving No. 3 on this page shows the relative positions of the ship, the torpedo, and the boat from which it was fired by an electric wire: the figure *a* representing the place where the boat lay when the torpedo was lowered from its side; while the figure *b* shows the place to which the boat had been removed before the signal of firing the torpedo was given. The depth of water beneath the keel of the ship was a few inches more than 12 ft.

hood of the metropolis, it falls considerably short of what has been done by the same means and appliances in the great seats of northern industry, and notably at Bolton, in Lancashire, where a block of steel weighing 250 tons was cast, by the aid of Messrs. Ireland and Sons' patent upper-twyer cupola furnace. The purpose for which the huge mass at East Greenwich and another block of smaller size, weighing 57 tons, have been cast, is connected with one of the most important branches of modern production. Wherever iron has been hitherto used, there is a growing tendency to substitute the kind of steel which is made by the Bessemer process. Several railway lines are gradually adopting the more durable and, by consequence, the safer material; and the superiority of steel ships over those constructed of simple iron has been strikingly exemplified in the case of the *Clytemnestra*, which vessel rode out the hurricane or cyclone, in Calcutta river, last year, though subjected to accidents a tenth of which might have sufficed to send any ordinary ship to the bottom. With regard to the employment of Bessemer steel on railways, it has been shown that a rail of this tenacious metal may be so twisted that, in a straight length of six feet, the outer spiral edge will measure nine feet and an inch. Such a

some in Germany, some in America, and one in the Island of Java. The smaller of the two blocks at East Greenwich was cast on the preceding Friday, and the upper surface was still of a purple heat and emitted sparks when scraped with an iron bar. The large mass, cast on Tuesday, will take about six weeks to cool. The liquid metal was poured into the sunken mould—a large square hole, like a tank-pit—in quantities of about four tons every twenty minutes, and the entire operation was accomplished between light and dark. These two blocks, which are within a few yards of each other, are to serve as anvils for steel hammers, when the new works of Messrs. Bessemer shall commence their active course of utility. The fine buildings, just finished, adjoin the new ship-building yard of Messrs. Maudslay, Sons, and Field, and contribute notably to the changed and thriving aspect of the once bare marshes of East Greenwich.

PHOTOGRAPHY.

PHOTOGRAPH OF THE ECLIPSE.—We understand that Mr. Warren De La Rue took a photograph of the lunar eclipse of the 4th instant. The atmosphere

H.M.S. TERPSICHOE, AS DAMAGED BY THE AMERICAN TORPEDOES.

The Engraving No. 1 shows the general longitudinal lines of the ship, with the hole made by the explosion of the torpedo, as it appeared on the 11th inst., when the *Terpsichore*, having been floated and brought into dock at Chatham, was carefully examined by the officers appointed for that purpose. An enlarged view of a portion of the outside planking around this hole is also given.

The Engraving No. 2 presents a cross section of the vessel, showing very minutely how her timbers were shivered. In the parts marked *a* the knees are seen as broken through the throat—viz., two on the starboard, and four on the port side.

GREAT CASTING OF BESSEMER'S STEEL.

The operation of casting a cubic block of steel, of the enormous weight of one hundred tons, was successfully accomplished on Tuesday week, at the new works of Messrs. Bessemer and Sons, at East Greenwich. Although this is by far the largest work of the kind ever attempted in the neighbour-

hood of the metropolis, it falls considerably short of what has been done by the same means and appliances in the great seats of northern industry, and notably at Bolton, in Lancashire, where a block of steel weighing 250 tons was cast, by the aid of Messrs. Ireland and Sons' patent upper-twyer cupola furnace. The purpose for which the huge mass at East Greenwich and another block of smaller size, weighing 57 tons, have been cast, is connected with one of the most important branches of modern production. Wherever iron has been hitherto used, there is a growing tendency to substitute the kind of steel which is made by the Bessemer process. Several railway lines are gradually adopting the more durable and, by consequence, the safer material; and the superiority of steel ships over those constructed of simple iron has been strikingly exemplified in the case of the *Clytemnestra*, which vessel rode out the hurricane or cyclone, in Calcutta river, last year, though subjected to accidents a tenth of which might have sufficed to send any ordinary ship to the bottom. With regard to the employment of Bessemer steel on railways, it has been shown that a rail of this tenacious metal may be so twisted that, in a straight length of six feet, the outer spiral edge will measure nine feet and an inch. Such a

proof is of great value when the friability of common iron is considered, especially if crystallised by such intense cold as has been known to cause many accidents in Canada. One, and indeed the main peculiarity of these large castings at Messrs. Bessemer's works is in the fact that the operation is performed on the spot where the massive blocks are required for future service. It would, indeed, have been almost impossible to convey them elsewhere; and the only movement they will now undergo will consist in their being turned completely over, so that what is now the upper surface will become the base. The cupola furnace lent by Messrs. Ireland and Son for reducing the vast quantity of Bessemer steel to a liquid condition melts at the rate of thirteen tons in an hour, and is charged with three hundredweight of coke to fifty hundredweight of metal. The saving of fuel is one among many advantages belonging to these furnaces, of which there are ten at Woolwich Arsenal, effecting an economy of coke to the extent of £2,000 a year. It seems that there are about 500 of them in operation in many parts of the world,

having been clear, the image is said to be excellent, and affords another proof of the important advantage now open to observers who make use of photography. When it is understood that an instantaneous image of a phenomenon can be taken, it will be seen that by no other means could the various movements to which our satellite is subject be so well observed and recorded as by photography. By associating this new image with one of a former eclipse, Mr. De La Rue obtains a stereoscopic effect singularly remarkable. To a practised eye the bulging hemisphere of the moon appears almost transparent, comparable to a huge glass shade covering a flat surface.

MR. CORMACK BROWN, photographic artist, of Greenwich, has published a series of photographs of various groups of the old sailors and their friends, setting out from the gates of Greenwich Hospital or lingering within the precincts, on the day of their departure. The photographs give faithful and characteristic portraits of some of those familiar figures.

A NEW ANGLE MEASURER.*

This instrument, which I have lately contrived, is on the principle of Schmalcalder's quadrant, but of dimensions small enough for the waistcoat pocket. In the Schmalcalder, moreover, a prism is used for reading off the angle at the same time that the object is viewed. In mine, the divisions are read off by a lens, and a needle point, passing through the side of the tube, and close to the divided wheel, forms the index. The object is seen with the other eye at the same time; the instrument being elevated or depressed, till the needle point appears to be in contact with the object as well as with the division of the circle. The angle of altitude is thus indicated. The drawings are of full size. I add a description and measurements of the instrument. A flanged wheel 11.10 inch diameter, has one half and a little more divided into degrees, the surplus being for index error; edge of wheel 2.10 wide; flange on each side about 7.100 deep. Within this flange on one side is a large-headed screw of brass, and on the opposite side a triangular piece of copper to which it is attached. The screw passes through a slotted hole in the wheel. The screw and piece of copper form a counterpoise to the wheel, and the slot allows of adjustment of the Zero point.

A brass tube 2.2-10 long and 4.10 diameter is filed out at one end so as to admit the above wheel, which is suspended as *delicately as possible* by a fine pointed screw on each side, the points of which screws enter a very fine hole, drilled in the axis of the wheel; upon the nicety of this suspension the accuracy of the instrument depends.

An aperture is made in the tube, near the wheel, to admit light for reading off the divisions, and moreover at this part the interior of the tube is silvered.

At A, a needle point passes through the side of the tube to furnish an index, as before stated.

The other end of the tube carries a lens of 1.7-10 focus, for viewing the needle point and divisions of the wheel. Some time since I gave Mr. Elliot, optician of the Strand, permission to make similar instruments if he wished to do so. He may possibly have some in stock, but of this I am not informed.

For measuring a short base line I use, with the angular instrument, a light rod of deal, 5 feet in length and $\frac{1}{4}$ inch square. This is attached by a joint at the centre to a walking stick. A short base line is readily measured by this—merely marking by a scratch on the ground each length of 5 feet as you proceed. To register the number of lengths, I have a small toothed wheel, $2\frac{1}{2}$ inches in diameter, which is attached to a foundation plate by a screw in its centre. A spring catch enters the teeth. Thus, by moving a tooth for each ten or other lengths of the measuring rod, an accurate account is kept. Instead of the toothed wheel an account may be kept by shifting a number of marbles from one pocket to the other.

We hope the following hint may also be of service. Having made one of the reflecting levels (a very useful pocket-companion) described in *Heather's Treatise on Mathematical Instruments*, p. 120 (Weale), I had difficulty in making the line scratched on the mirror perfectly horizontal. This difficulty may be obviated by adopting a circular instead of a square shape for the centre of the instrument. In this a cell for the mirror may be turned, and it can then be adjusted with the greatest accuracy.

A 32-POUND rocket sent up perpendicularly at Shooter's Hill is said to have risen 6,000ft., and was seen at Deal. A 24-lb. rose 4,500ft.; a $\frac{1}{2}$ -lb., 2,400ft.; and a $\frac{1}{4}$ -lb., 1,500ft. The object was to determine the longitude on Whiston's plan.

The velocity of waves is as the square root of their breadth. Thus, if the summits of two waves are 16ft. asunder, and of others 4ft., the velocity is 2 to 1. A pendulum equal to the breadth vibrates in the time the waves proceed.

To supply the 613 iron furnaces in blast during 1864, 10,064,890 tons of ore were required. From this and a small quantity of imported ore there were smelted 4,767,951 tons of pig iron. This was distributed over 6,338 puddling furnaces, and by the aid of 705 rolling mills, converted into merchant, bar, and other iron.

BIRTH AND GROWTH OF THE IRON TRADE.

By JAMES ROBERTSON.

(Continued from page 52.)

Diodorus speaks of Elba, where the inhabitants dig ironstone from the ground, much of which metal is in this sort of stone; that the workmen first cut the stones in pieces, and then melt them in furnaces prepared for the purpose, and the implements made of this iron were conveyed by merchants into several parts of the world. Pliny gives a tolerable description of the manufacture of iron, and speaks of steel, and the steel-drinking cups dedicated to the temple of Mars; he also testifies as to the universality and wide diffusion of ironstone, and the tempering of iron by immersion; he also mentions the loadstone, and how Dinocrates made an arched roof thereof, in which was to be placed an iron statue of the Princess Arsinoe, so that the statue might seem to hang in air suspended by nothing.

The Turks, before they became a nation, were employed in the manufacture of arms in Asia, as you will find from Gibbon, the historian: they turned the arms they made against their masters, and founded an empire. Our earliest travellers in Africa prove the existence there of iron furnaces, blown by bellows made of goats' skins, and that the iron was made with charcoal; the furnace was of rude construction, and destroyed after every smelting, in order to obtain the iron which the bottom of the furnace contained; but in the Himalaya Mountains the Indians had a hole at the bottom of the furnace, through which the molten metal flowed; this hole was tamped with clay, so that you see the method now in use of running the iron from the furnace is of no recent date. The intercourse between the people of Cornwall and the Phœnicians and Greeks

it till about the 12th century, that date at which commences the true greatness of our history, civil, political, and warlike. From the Norman conquest till the end of the reign of King John, iron and steel were imported from Germany and the Continent, and sold at steel yards by German merchants. There is no precise data to prove when the art of casting was first introduced, but cannon was used by Edward by III., in 1327; it is supposed to have been then used for the first time in England by that monarch. Cannons, or bombards as they were called, were all made of iron till the middle of the fifteenth century, when bronze was first discovered. Hardware was, during the period from 1350 to 1450, imported from the Continent, until a petition to Parliament produced an Act which prohibited the importation of swords, scissars, and knives, so that you see protectionists were strong and free traders unknown, in those early days of the iron trade; but even at that time Yorkshire and particularly Sheffield, was celebrated for its cutlery, although the cutlers could not then compete against the foreigner in the manufacture of those articles in which it can now compete, even in the face of enormous duties, against the world.

But as our manufacture advanced and developed it was arrested by a new difficulty; hitherto iron had been produced from charcoal alone, and the spacious forests of England were fast disappearing before the devouring and ever-blazing furnace. The efficiency of the Navy was then, as it is now, essential to our independence and security, and how could that be maintained if the timber of which our ships were built was taken to produce the cannon and the shot with which our ships were to be armed? The question was natural enough, the year 1558 an Act was passed forbidding the cutting of any timber for the furnace over one foot square area of the root,

growing within fourteen miles of the sea, or any part of any river, so far as that river was navigable, with the exception of some parts of Kent and Sussex. Iron was then made in Sussex and in and near London, till at length ironworks were prohibited within twenty-two miles of London. Many of the ironworks were consequently stopped for want of fuel, and in the reigns of James I. and Charles I. great efforts were made to find a substitute for wood as fuel, and attempts made to smelt iron with coal; these attempts were far from successful, strange as it may appear to us, and many large fortunes lost, in endeavouring to make iron by coal instead of wood. Patents were issued

by Charles I. for the new process, but these patents were unproductive to their possessors, and although high learning and the greatest intelligence of the time had been called in to aid the invention, yet it was a failure. Iron could be made by the new process, but it was not good; it was not saleable—no wonder. The nation had been used to charcoal iron, and would not be put off with cinder bars; so the patentees complained bitterly to the king and the nation—to the king, of the great losses they had sustained; to the public, that they would not see the value of their discovery, and appreciate a quality in their pit coal iron which it had never possessed.

In 1619, Edward Lord Dudley's invention of making iron with pit coal was making progress towards perfection, but his discovery was retarded in its development by the political commotion into which the State was plunged at that period; however, 300 furnaces were then at work, as we find from parliamentary reports. Lord Dudley's works were destroyed by a mob, and himself nearly ruined by his endeavours to perfect his process. For more than a century the iron trade languished, in consequence of the scarcity of fuel, and the requirements of the country were supplied from abroad, particularly Sweden and Russia. The 300 English furnaces of the previous century had dwindled down to fifty-nine, and the total production of the year 1740 was only 17,000 tons; whole production of Yorkshire was in that year 1400 tons, and Staffordshire only 1000. The demand for iron, however, was daily increasing; improvements in machinery were being made, the cumbersome bellows, worked by oxen, were discarded for the blast-engine, and the first blast cylinders of any magnitude were used at the Carron Ironworks, just 100 years ago. The quantity of iron now rapidly increased, and by the beginning of the present century the estimated production yearly was 250,000 tons. This was a tolerably rapid stride in sixty years—viz., from 1740 to 1800, in the

produced a remarkable degree of civilization amongst the Britons, and when Cæsar landed in this country he was opposed with weapons of iron, and discovered that the manufacture of iron had already made great progress. It is also tolerably well authenticated that our ancestors had discovered, or been taught, the arts of working tin, lead, brass, and iron, and that the Gauls traded with the Britons extensively in iron. I wonder how the ancient Britons kept their ledgers in those days, but there is nothing to satisfy our curiosity on this head. Our ancestors, under Cassibelanus, fought with great valour: they had many thousands of chariots, armed with scythes and hooks, which did great damage to the Roman army as they charged them; and if our ancestors were somewhat barbarous, and knew but little of the arts, they gave us even then a lesson of patriotism and heroic valour, which has never yet been wanting in the hour of England's need, and a courage which I trust may descend unimpaired to a long line of future generations. These scythes were doubtless made in Britain, and from this period (B.C. 55), we may date the iron trade of Great Britain.

When the Roman Emperor Adrian came into Britain (A.D. 120) he established a great military force, or arsenal, at Bath, for the construction of arms and munitions of war, whence they were distributed to the various Roman stations throughout the kingdom. This was a college of armourers, and they bore very much the same relation to the army that the artillery does to the armies of Europe in our own day. The iron was brought from the Forest of Dean and the hills of Monmouthshire, and manufactured at Bath; and the Romans continued to work the mines for 350 years (A.D. 409), about which time they finally abandoned Britain. Many traces have been found in Yorkshire and elsewhere, which gives proofs of the existence of the iron foundries of the Romans during their dominion here. The Saxon invasion paralysed the iron trade, and no mention is made of

* By the Rev. N. J. Heineken in the *Journal of Science*.

former of which years the production had been only 17,000 tons. The inventions of the deceased Mr. Cort had a wonderful effect in stimulating the production of iron, and from the date of his discoveries begins the epoch of the stimulus which has led to the present enormous development of the iron trade. Bars had been always hammered before this to the required sizes, but Mr. Cort introduced the application of rollers, the importance of which we can now fully appreciate; great as were the discoveries of Mr. Cort, he never received any benefit from them. The story of his wrongs is well known. Government seized upon his works at Gosport, sold them, prevented his carrying out his inventions; and in restitution of this great injustice gave his widow a small annuity, and now gives his only son, who is far advanced in years, the trifling sum of £50 a year, after having spent the greater portion of his life in seeking for redress. The coke refinery was also discovered about this time (1810), and the development of the manufacture advanced exceedingly. It is related, in a work on the Turkish empire, that an Armenian of Constantinople had discovered the art of casting iron which, when it came out of the mould, was as malleable as hammered iron; some of the productions were shown to M. de Gaffron, Prussian charge d'affaires at Constantinople; he was struck with the importance of the discovery, and instituted enquiries for the inventor, but he had died poor and unrequited, and his secret perished with him. Many valuable discoveries have undoubtedly been lost to the world in a similar manner, and probably as many by the obstinacy and prejudice of the learned as the ignorance of the unskilful.

(To be continued.)

ASTRONOMY.

Some important steps have been gained and some real contributions made to exact science during the past year in the department of Meteoric Astronomy. A summary of these by A. S. Herschel, Esq., formed the next important communication made to the Royal Astronomical Society. As regards the height of shooting stars it appears from a comparison of several hundred observations dating from the end of the last century, that it may be stated respectively at 72 and 52 miles at first appearance and disappearance above the surface of the earth, with a probable error of not more than three miles. The average velocity of shooting stars in sixty-six instances is 35 miles per second. In this respect fire-balls resemble shooting stars, but they differ from them in penetrating more deeply into the atmosphere; should they arrive within 20 miles of the earth's surface a violent concussion is usually produced, and stones are not unfrequently precipitated from the meteor. One of the most remarkable observations of a fireball on record was made by Dr. Schmidt, at Athens, on the morning of the 19th of October, 1863. A fireball of surpassing size and brilliancy was examined for 14 seconds by Dr. Schmidt, in a telescope with a magnifying power of eight diameters. The meteor was twin or double, attended and followed by a tribe of lesser meteors advancing side by side together, with parallel motions of translation, until the whole were extinguished. Respecting the origin of aerolites, it has been found from a microscopic examination of the mixed minerals of which they consist, that these crystals differ in some essential particulars from those of ordinary volcanic rocks, but their consolidation must have taken place from fusion in masses of mountain size. The planetary velocity (at least 15 miles per second) of the meteor, which produced the recent aerolites of Orgueil, greatly exceeds the ballastic forces which can be supposed to reside on the surface of the earth or moon. We are therefore compelled to give a wider range to conjecture with regard to aerolites, and to suppose that they are projected from small planets near and within the orbit of the earth. Aerolites commonly fall in the daytime. They circulate round the sun in such countless numbers, or else they bear such close a relationship to the earth that they in all probability strike the earth daily in its path.

RAISING SUNKEN VESSELS.—We mentioned some time ago a collision which occurred in the port of La Joliette, Marseilles, and in consequence of which a lighter, laden with 275 tons of coal, was sunk. This vessel and its cargo have been recovered by the aid of the narval, an apparatus invented by M. Eyber, a civil engineer, and which consists simply of a vast air-chamber, affording through its buoyancy purchase enough to admit of its raising enormous weights.—*Galignani.*

The use of nitro-glycerine for blasting purposes is proposed. It is said to offer many advantages over the old method.

AMERICAN LATHE CHUCK.

This modification in the chuck for lathes, says the *Scientific American*, is intended to facilitate setting irregular forms, such as eccentrics or cams, and it is to be applied particularly to scroll chucks, which are arbitrary in their motions and cannot be set out of the centre unless one of the jaws be taken out and started on the thread after the other jaws have been run in one turn or two. Even this will not always bring the work true, and some simple arrangement of the kind here shown will prove a great convenience. The details are as follows:—

FIG. 1.

A is the plate, which is fastened securely to the main chuck, forming a part thereof, into which the dovetail projection of the plate, B, slides; C is the hub, which screws on the lathe spindle; D is the screw, by the use of which the chuck may be adjusted to any required position with the spindle of the lathe. The face side of the dovetail projection is laid off to fractional parts of an inch, and marked with figures, so that there is no difficulty in setting the work accurately. The screws, I, hold the piece to which the screw, C, is secured firmly to the plate, B. F is the gib, which is tightened up as it wears, by screws, as usual. G G (Fig. 2), are slots through which bolts, E, pass, for the purpose of firmly securing plate, B, to the chuck, A, at any desired point.

FIG. 2.

The utility of this improvement is universally conceded by all first-class machinists who have seen it, and the proprietors of several of the largest and best machine shops have already expressed a wish to adopt it in their own workshops. This attachment may be applied to any size or kind of chuck already in use, equally as well as to new ones, and will add only from one to one and a half inches to the depth

the entire chuck, including the attachment. Though only one sliding plate is represented in the engraving, says the inventor, another slide can be added if necessary. The inventor and patentee is W. Haskell King, 561, River-street, Troy, New York.

PRACTICAL RESULTS OBTAINED FROM BLAST FURNACES BY THE USE OF HOT BLAST OF HIGH TEMPERATURE.

It is not proposed to enter fully into the history of the numerous attempts which have been made to raise the blast for blast furnaces to a very high temperature, nor will the author occupy much time in the description of the means by which the desired result has been obtained, as a full account of the apparatus was given at the meeting of this association held at Oxford, though the paper on the subject was not printed in the Transactions.

In 1861 experimental stoves only, on the new plan, had been erected and worked for heating the blast for one tuyere out of the five used for one blast furnace. Such satisfactory results were, however, obtained, that it was clear that the difficulty of procuring blast of very high temperature had been overcome, and Messrs. Cochrane and Co., of Woodside Ironworks, Dudley, and Ormesby Ironworks, near Middlesbrough-on-Tees, forthwith erected large stores on the new plan for a complete blast furnace, and it is now proposed, with your permission, to lay before the section the results obtained during upwards of four years' practical working with these stoves.

The effect of heating air on the new plan was that a temperature of blast of 1,150 deg. Fah. was obtained, instead of only 600 or 700 deg., as with cast-iron pipes in the common stoves; there was no loss of blast from leakage, owing to cranked or damaged cast-iron pipes; the iron produced was of rather better quality; twenty per cent. more iron was made from the same furnace, and fully 5 cwt. of coke was saved in the blast furnace per ton of iron made.

The details of the construction of the new stoves will be readily understood by all who have studied the subject.

1stly. There are two stoves, which are heated alternately, and used alternately in heating the cold air; these are filled with brickwork "set open," or with small spaces between the bricks, and termed "regenerators," on the principle of Mr. Siemens' "regenerator furnaces," as now so largely and successfully used in glass houses, gas works, ironworks, &c., &c., both for obtaining great heat and economising fuel.

The outside of the stoves are of thin wrought iron plate lined with firebrick, the iron skin being necessary to retain the blast under pressure, while the firebrick resists the heat.

2ndly. There are provided for the purpose of heating the stoves, valves for the admission of gas and air into a central flue, where combustion takes place when a stove is being heated, the products of combustion passing up the flue, and down through the mass of firebricks forming the regenerator, and escaping at the bottom to the chimney, after the whole of the heat has been abstracted by the firebricks; the temperature of the chimney being from 212 degrees to 250 degrees, or thereabouts, during the time a stove is being heated, viz., for a period of four hours.

Then, when a stove is hot, the gas and air are turned off, the chimney valve shut, and the cold blast is turned on at the bottom of the regenerator, and passes up through the bottom courses of brickwork in the regenerator, thus very quickly becoming heated; and passing in the heated state up through the remaining courses of the brickwork, and down the central flue, through the hot blast valve to the blast furnace; the process of absorption of heat by the air being so perfect that, as long as a few of the top courses of brickwork remain hot, the blast is well heated, the variation in the temperature of the blast being only about 100 degrees Fah., with four hour changes.

3rdly. The gas for heating the stoves is supplied from gas producers, similar to those commonly used by Mr. Siemens for his regenerator furnaces, and which have already been described before this Association. They consist of a simple brick enclosure or fireplace, with bars near the bottom, for the admission of a very small quantity of air. The gas is formed by the slow combustion of a very thick fire, supplied with poor coal, or slack down a slope or hopper, the gas passing off from above the fuel through pipes to the hot blast stoves. Gas may,

* By E. A. Cowper.

however, be taken from the top of the blast furnace for heating the stoves, provided proper arrangements are made to separate it from the dust which comes over from the blast furnace with it; and judging from recent practical experiments, it is certain that there are several ways in which this may be done with perfect success.

The late Mr. James Beaumont Neilson, who did so very much for the iron manufacture by his original invention of the hot blast, in 1829, was sufficiently long-sighted to predict the advantages that would flow from the use of blast of very high temperature, though, as it happened, he was limited to what could be obtained from passing the air through iron pipes exposed to a fire, as in common stoves.

Mr. Neilson said:—"In the new regenerator ovens that had just been described the great capacity of firebrick for heat had been well taken advantage of, and a very important step in advance had been made by giving the means of raising the temperature of blast much above the extreme limit practicable with the old ovens; and he considered this would be productive of the greatest benefit in the working of the blast furnace. . . . He had no doubt the make of iron would be considerably increased by the higher temperature of blast given by the regenerator ovens."

These anticipations have been fully borne out in practice during upwards of four years' regular working of the stoves. The high temperature of the blast produces such an improved effect in the furnace that the "burden" is increased so as to save fully five hundredweight of coke per ton of iron made; and as there is less fuel supplied, so there are less impurities taken in, and the quality of the iron is improved, the "tuyere-breasts" do not "work hot," or burn, or give more trouble than usual, as the burden is increased as just stated. The same furnace is, of course, enabled to do more work, the "make" being increased fully one-fifth; so that a given plant produces 20 per cent. more iron per annum, besides saving nearly 3s. per ton for coke.

There is less friction or loss of pressure of blast in the stoves than in common ones, and there is no loss of blast by leakage through cracked or burst cast iron pipes or joints. More stoves are now being erected on the same plan.

GENERAL NOTES.

It is proposed to hold another exhibition of the works of the industrial classes of both town and country during next year at the Agricultural Hall, Islington. The special features of the exhibition will be the encouragement of skilled workmanship, amateur productions, facilities for the sale of articles, machinery in motion, musical gatherings, lectures on popular subjects, manufacturing process in operation, flower shows, conversations of masters and workmen, free admission of school, free reading-room, prizes for evergreens, &c., in pots and a small garden.

GALE'S PROTECTED GUNPOWDER IN AMERICA.—Mr. Handel Cossham, who left England a short time since with Sir Morton Peto and other English capitalists for a visit to the United States, has there introduced Gale's process for protecting gunpowder with the same success as has attended the experiments in England. The New York papers publish the particulars of an interesting series of experiments tried at the Jersey City Locomotive Works, for testing the process, which were very satisfactory.

DRILLING ROCKS.—A machine has been invented by Mr. Robert Hood, of Drayton, Ohio, which consists in the employment of a spiral lifter, in combination with a tappit extending from a sleeve fitted in the drill or drill-rod, and with an arm extending from said sleeve in the cam slot, in such a manner that, by the action of the cam slot or arm, the tappit is held in contact with the thread of the feeder until it arrives at the end of the stroke, when the same, by a curve in the cam slot, is thrown out of contact with the feed-screw, and the drill is allowed to drop, and, while being thrown out of gear with the feed-screw, it is turned, causing it to strike a different spot on each stroke. By this arrangement two or more drills can be operated by means of the same lifter and by the same driving power.

Mr. SMITH stated that we dig annually 84 millions of tons of coal from our pits. The combustion of a single pound of coal, supposing it to take place in a minute, would be equivalent to the work of 300 horses; and if we suppose 108 millions of horses working day and night, with unimpaired strength, for a year, their united energies would enable them to perform an amount of work just equivalent to that which the annual produce of our coal-fields would be able to accomplish.

THE total production of the collieries of Prussia in 1864, was estimated at 42,394,500 tons.

IMPROVED PUDDLING-FURNACE.—Mr. J. Williams, Montreal, Canada East, claims—1. the novel arrangement in a puddling-furnace of a blind grate with the ordinary grate, together with the combination of slide-doors, trap-doors, towed-holes, and air-chamber, whereby for all the fuel consumed in the blind grate the benefit is received into the body of the furnace on the iron, with much less of the fuel passing up the chimney than in the ordinary furnaces. —2. in the different grates he claims the introduction of the trap-doors for letting the ashes, cinders, &c., fall into the external ash-pit, and thus save the handling out of ashes when the furnace is in operation, thereby effecting a saving of time. 3. He claims the peculiar arrangement of water boshes, whereby water may be employed without the danger of an explosion from the generation of steam.

NEW METHOD OF FERTILIZING SOIL.—Two gentlemen, members of the Agricultural Academy attached to the University of Bonn, M. Nounenbruck and Dr. Hardstein, have conceived a new method of assisting the formation of humus, and which, it is said, has been put into successful practice at Annaberg, near Bonn. The method is the introduction of air beneath the surface of the soil; a system of pipes, like those used for drainage, but pierced full of small holes, are laid at depths of from three to six feet beneath the surface of the ground, is placed in connection with a furnace, which keeps up a continual draft through the pipes, and thus the subsoil becomes so impregnated with air, that when the connection with the atmosphere is closed, the fire continues to burn in consequence of the superabundant oxygen which is conveyed to it by the pipes.

ECONOMIC RAILWAYS.—The French Government has recently purchased the free use of a locomotive designed by an engineer named Rarchaert, for the purpose of running on light rails, and passing over sharp curves and steep inclines. M. Rarchaert's engine, with the tender and fuel, does not exceed twenty tons in weight, has four pairs of wheels, coupled, and will not require rails exceeding forty pounds in weight to the metre. The pressure of each wheel would thus be equal to two tons and a half, while that of the locomotives in use on the great lines ranges between five and six and a half tons, and the rails themselves weigh from seventy to eighty pounds per metre. The engine is said to be able to draw 640 tons, in addition to its own weight, on a level, 310 tons up an ascent of 5 in 1,000, and so on, to 74 tons on a gradient of 30 in 1,000; and, at a speed of from eighteen to twenty-four miles an hour, it will, according to the inventor, work safely on curves of a minimum radius of sixty metres; and, therefore, by adopting gradients varying from 12 to 30 in 1,000, nearly all necessity for tunnels, viaducts, and embankments would be avoided. The inventor calculates that under his system the average cost of these local railways will not exceed 60,000*fr.* the kilometre, or less than £4,000 per English mile.

GALACTOZYME.—Galactozyme, or galozyme, is the result of the fermentation of milk by means of yeast, and is used, as stated by Dr. Schnaepff in the *Gazette-Heldouandaire*, by the inhabitants of the Steppes of Russia as a sovereign remedy in phthisis. Cases are mentioned in Dr. Schnaepff's articles where the patients gained considerably in weight by taking half a tumblerful night and morning; but the doses must be regulated by the peculiarities of the patients. Nor is it indifferent whether the fermentation is carried to a greater or less extent.

ACCORDING to Prof. Tyndall 474,439,680,000,000 of waves of light enter the eye in a second of time to produce the impression of red colour. To produce the impression of violet a still greater number of impulses is necessary: it would take 57,500 waves of violet to fill an inch, and the number of shocks required to produce the impression of this colour, amounts to 699 millions per second. The other colours of the spectrum rise gradually in pitch from the red to the violet.

WEBSTER, in his "History of Metals," published in 1671, makes mention of two places in the West Riding of Yorkshire, where formerly good argenteiferous lead ore had been procured. One of the places was Bronghite Moor, in the parish of Slaithburn; the ore held about the value of 67lb of silver in the ton; the other place was Skelhornfield, in the parish of Gisburn; it had formerly belonged to a person of the name of Pudsey, who is supposed to have coined it, as there were many shillings in that county which the common people called Pudsey shillings.

FURTHER ADVANCE IN THE PRICE OF COPPER.—In consequence of a further advance of £5 per ton in the price of copper, the principal firms yesterday raised the price of brass and copper wire and tubing a halfpenny per lb., and yellow metals a farthing per lb.—*Birmingham Gazette*.

CHEMISTRY.

RESULTS OF THE EXPLOSION OF NITRO GLYCERINE. The new blasting material is a light-yellow oily fluid, a compound of glycerine and nitric acid, its chemical formula being $C_3H_5O_3(NO_3)_3$, which gives 18 parts of oxygen; and Mr. Nobel claims that as by combustion the carbon takes 12 atoms of oxygen, and the hydrogen 5, its complete combustion leaves a surplus of O₁ only. He states, moreover, that each 100 parts of exploded blasting-oil leaves a residue of—carbonic acid, 58; water, 20; oxygen $3\frac{1}{2}$; and nitrogen, $18\frac{1}{2}$ —100; and that as the specific weight of the oil is 1.6, one volume produces nearly 1300 volumes of gas—that is to say, steam, 554; carbonic acid, 469; oxygen, 39; and nitrogen, $236\frac{1}{2}$ —1298 volumes. Weight for weight, the blasting-oil bears very favourable comparison with gunpowder, which is calculated to produce ordinarily about 250 volumes of cold gas only; the nitro-glycerine would, consequently, appear to be, other things being equal, about five times as effective as gunpowder. But Mr. Nobel goes further than this, for he remarks that it is difficult to determine the degree of heat produced by an exploding substance, and that, according to theory, the blasting-oil, on account of its complete combustion, ought to develop a more intense heat than gunpowder, and this appears to be borne out by experiment; whence he assumes that the heat developed by the explosion of nitro-glycerine is twice that generated by gunpowder, and from this calculates that nitro-glycerine, compared with gunpowder, possesses about 13 times its power, when volumes are considered, and 8 times its power for equal weight; and that owing to its rapidity of explosion its advantages are still greater.

ACADEMY OF SCIENCES.—OCTOBER 9.

M. de Cizancourt presented a memoir "On the Allotropic Conditions of Iron." The author, like Berzelius, recognises two allotropic states of this metal, and adopts the same names for them—ferrosium and ferricum. Ferrosium is the metal from ores containing protoxide; ferricum is obtained from the anhydrous peroxide ores. The most characteristic form of ferrosium is the white crystalline cast iron (Spiegel Eisen), commonly obtained from the carbonate, and is best produced at a low temperature. This form of iron has a strong affinity for carbon. Chemically it must be classed among the bodies which unite with one atom of oxygen. Ferricum also combines with carbon at high temperatures, but deposits it again on cooling. This form of iron gives the malleable metal, and also blistered iron. The author states that while ferrosium easily passes into ferricum, the inverse change cannot be effected. Ferricum belongs to that class of bodies which combine at least with three atoms of oxygen and often more, but always an uneven number of atoms. This memoir will have considerable interest for metallurgists, and we shall therefore give it at length.

M. Bultinck presented a note "On the Use of Magnesium in Voltaic Piles in Place of Zinc." Our readers can imagine the results. The author shows that a short chain of twenty elements, each composed of thirty-five millimetres of thin silver and magnesium wires, wound about pieces of caoutchouc and properly connected, will produce all the effects, chemical, physical, and physiological, of a long Pulvermacher's chain when simply moistened with pure water.

M. Jennet presented a note "On the Clarification of Peaty Waters by Alum." Most of our readers will have heard of a method of clarifying and rendering portable certain muddy waters by stirring or shaking up with them a very small quantity of finely powdered alum. Then, after standing a few minutes, the suspended impurities deposit, and the water becomes perfectly bright, and at the same time extremely palatable. The explanation of this is as follows:—In dissolving, the alum splits up into sulphate of potash and sulphate of alumina. The former remains in solution in the water; the latter decomposes, and the insoluble alumina unites with and carries down the suspended organic impurities; while the sulphuric acid acts on the alkaline and earthy carbonates, forming sulphates and setting free carbonic acid. The biphosphate of alumina, although slower in its action, the author thinks would be a better clarifier if the carbonic acid set free did not dissolve some of the neutral phosphate. Some persons will, perhaps, see a recommendation in what the author considers an objection.

At the Birmingham Industrial Exhibition last week, the first prize, of the value of £25, was awarded to Mr. Peter Gaskell, the inventor and patentee of the cab indicator, which shows the distance the cab goes, and the amount the passengers have to pay.

PATENT LIST.

(From the Commissioners of Patents' Journal.)
LIST OF SPECIFICATIONS, &c. PUBLISHED DURING THE
WEEK ENDING 20TH OCTOBER, 1865.

2571. Bricks, V. J. B. Gormax.
2629. Cabs, checking the payments of fares in, H. A. Bonneville.
2561. Carriages, breaks for, A. R. Shaw.
2623. Carriages propelled by manual power, T. Du Bonlay.
2137. Cast steel, &c., manufacture of, R. A. Brooman.
2617. Cars, &c., break for, T. Warturton.
2587. Compound cylinder engines, J. Howard.
2593. Cork, cutting and shaping, L. Villette.
2537. Cotton, &c., machines for opening and cleaning, E. Marsland and P. Williams.
2531. Disks, &c., revolving cover for, C. P. Button.
2611. Doubling machines, flyer used in, M. Walker.
2217. Electrical telegraphy, R. Laming.
2553. Fire-arms, breech-loading, J. Millar and B. Burton.
2569. Fires, apparatus for extinguishing, W. H. Phillips.
2529. Fires, apparatus for lighting and reviving of, C. J. Webb.
2615. Gas lamps, J. J. Parkes.
2569. Gun carriages, G. W. Rendel.
2417. Hair, machinery for brushing, F. T. and J. H. Brandreth.
2619. Harness for driving machinery, J. Crutcheff.
2445. Hydraulic pressure engines, J. Dreisornier.
2555. Injection to the human body, administering, W. R. Barker.
2461. Iron and steel, manufacture of, T. E. Cashin and J. F. Allender.
2537. Leather, L. G. Sourzac and L. Bonmail.
2523. Lucerne plant, making paper, &c., from the, C. D. Abel.
2597. Mangling and callendering, R. Walsley.
2613. Measuring, rules for, A. Nicholls.
1555. Metallic stuffing box, V. Duterne.
2547. Nap or pile of nap or pile fabrics, cutting or shearing the, W. B. Stocks, J. Whitlam, and W. Blakey.
2607. Pianofortes, G. G. Rich.
2621. Railway carriages and locomotives, M. Henry.
581. Railway carriages, &c., construction of, H. G. Craig.
2567. Rotary engines and pumps, R. A. Brooman.
2569. Scent and smelling bottles, T. Miles.
2551. Sewing machines, M. Henry.
2513. Sewing machines, wheel feed for, J. Hose.
2587. Spoons, forks, &c., D. J. Fleetwood.
2484. Sulphurous acid, obtaining, R. Reese.
2609. Ventilating apparatus, J. G. Woodward.
2601. Vessels, propelling, W. Clark.
1485. Wheat, &c., grinding, B. Wren.
2577. Wooden spools, T. Machin.
2599. Wool, &c., washing, J. Petrie, jun.
2573. Writing, pens used for, B. M. and D. Cameron.
2593. Wrought iron girders, J. Homan.
* * * Specifications will be forwarded from the Commissioners of Patent's Office, Southampton-buildings, Chancery-lane, by post on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post-office Order, made payable at the Post-office, 5, High Holborn, or Mr. Bennett Woodcroft, her Majesty's Patent Office. We cannot undertake to forward Specifications, or Books advertised from the office of THE ENGLISH MECHANIC.

WEALE'S SERIES.

A TREATISE ON GAS-WORKS, and the
Practice of Manufacturing and Distributing Coal Gas.
By SAMUEL HUGHES, C.E.
Second edition, illustrated, revised by WILLIAM RICHARDS, C.E.,
price 3s.
VIRTUE BROTHERS and Co., Amen Corner, London.

JUST PUBLISHED,

In Post 8vo., Cloth, with 17 Illustrations, 4s. post free,
THE SLIDE VALVE
PRACTICALLY CONSIDERED.

By N. P. BURGH, Engineer,
London: E. and F. N. SPON, 16, Bucklersbury.

FOR SALE.—Cylinder, Covers, Six Columns,
and shaft, with double crank of oscillating Engine, suitable for
driving a Lathe. Cylinder 3 1/2 in. diameter, 4 in. stroke. Cylinder
bored, trunnions, covers, columns, and shaft turned up. 42 1/2 in.
Address, W. O. SHEPPARD, Watling Works, Stony Stratford.

TO ESTABLISHED ENGINEERS AND BOILER MAKERS.

AGENTS WANTED in every Manufacturing
district, for the sale and application of Messrs. Ferguson, Thys,
and Co's.

PATENT NON-CONDUCTING COMPOSITION,

For preventing the radiation of heat or transmission of cold in Steam
Boilers, Steam Pipes, Cylinders, and all Heated Surfaces. A very
liberal Commission allowed. Apply to Messrs. FERGUSON, THYS,
and Co., the Creation Works, Mile End-road, London.

SECOND-HAND CASES OF MATHEMATICAL INSTRUMENTS, Theodolites, Levels, Pentagraphs, Quadrants, Sextants, Universal Dials, Protractors, Circumferencers, Prismatic and Beam Compasses, Ivory and Boxwood Scales, Lead Chains, &c., by Troughton and Simms, Elliott, Dolland, and others, at W. F. LAWLEY'S, 78, Farringdon-street, City. Photographic Cameras, Lenses, Magic Lanterns, Slides, Dissolving View Apparatus, Microscopes, Telescopes, Opera, Race, and Tourists' Glasses, by Voigtlander, B. & Dallmeyer, and others. Instruments bought or exchanged. Catalogues forwarded on receipt of three stamps for each.

JOSEPH STANLEY,

(Late Foreman at David Hart's.)

ENGINEER AND BUILDERS' PATTERN MAKER.

33, FIELDGATE-STREET, WHITECHAPEL-ROAD, E.
Patterns designed and arranged from instruction according to requirement.

HOLLOWAY'S PILLS.—Nothing preserves the health so well as an occasional alternative when the temperature is variable, and the nerves are unstrung. These Pills act admirably on the stomach, liver, and kidneys, and so thoroughly purify the blood that they are most efficient in warding off nausea, fever, diarrhoea, and dysentery, and other maladies so rife throughout our autumns. All who have the natural and laudable desire of maintaining their own and their families' health cannot do better than trust to Holloway's Pills, which will cool, regulate, and strengthen them. These purifying Pills are suitable for all climates, seasons, ages, and constitutions. They are the maiden's safeguard, the matron's safety, the young man's security, and the old man's comfort.

WEALE'S SERIES.

CATALOGUE ON APPLICATION.

CRANES AND MACHINERY FOR RAISING HEAVY BODIES, the
Art of Constructing, by J. Glynn. 1s.

STEAM ENGINE, by Dr. Lardner. 1s.

TUBULAR AND IRON GIRDEE BRIDGES, by G. D. Dempsey. 1s.

LIGHTHOUSES, their Construction and Illumination, by Allan Stevenson. 3s.

STEAM BOILERS, their Construction and Management, by R. Armstrong. 1s. 6d.

RAILWAYS, Construction, by Sir M. Stephenson. Capital and Dividends, by E. D. Chattaway. 2s. 6d.

CLOCK AND WATCH MAKING, and Church Clocks and Bells, by E. B. Denison. 3s. 6d.

STEAM AND LOCOMOTION, on the Principle of connecting Science with Practice, by J. Sewell. 2s.

LOCOMOTIVE ENGINES, by G. D. Dempsey. 1s. 6d. Illustrations, 4to. 4s. 6d.

MECHANISM AND CONSTRUCTION OF MACHINES, by T. Baker; and TOOLS AND MACHINES, by J. Nasmyth, with 220 Woodcuts. 2s. 6d.

MACHINERY, Construction and Working, by C. D. Abel. 1s. 6d. Illustrations, 4to. 7s. 6d.

STEAM ENGINE, Mathematical Theory of, by T. Baker. 1s.

Virtue Brothers & Co.,

1, AMEN CORNER, LONDON.

T. E. TAYLOR.

MODELLER OF NEW INVENTIONS,
LATHE, TOOL MAKER,

AND GENERAL MACHINIST,

110, FETTER-LANE, FLEET-STREET, LONDON, E.C.

Patterns made to drawing.

W. SPEECHLEY,

ENGINEER, MACHINIST,

AND LATHE MAKER,

No. 118, RAILWAY ARCH, VAUXHALL-WALK, S.

JAMES LEWIS.

(Late Lewis & Son),

ENGINEER, MACHINIST, LATHE & TOOL
MAKER, and Modeller of New Inventions.

41, GREAT QUEEN-STREET, LINCOLN'S INN-FIELDS.

(Late of 5, Wych-street, Strand.)

Machinery made to Drawings or Patterns, and Worked
out to Scale.

W. & A. GLOVER,

ENGINEERS, MACHINISTS,

LATHE, AND TOOL MAKERS,

191, OLD KENT ROAD.

SMALL SCREW CUTTING, TURNING, AND PLANING.

Fifth Edition, lately published, 8vo. cloth, now reduced to 15s.
(Postage 8d.)

**TREDGOLD'S PRACTICAL ESSAY ON
THE STRENGTH OF CAST IRON.** Edited by EDWARD HODGKINSON; together with HODGKINSON'S EXPERIMENTAL RESEARCHES. With 8 plates and numerous woodcuts.
LOCKWOOD AND CO., 7, Stationers' Hall Court.

SCREW CUTTER'S GUIDE,

Price 1s. 6d., or stamps.

Containing 115 Pages and nearly 3,000 Tables of Wheels, all different threads and pitches.

Tables for Tap-making for Engineers, 1/2 to 8 inches, Gas Taps 1/2 in. to 2 inches, Mr. Whitworth's thread and make.

A lithograph showing a new radius gear invented by the author of this work.

May be had at James Martin, 19, Wilson-street, New Cross-road, Deptford, Kent.

NATIONAL BOILER INSURANCE

COMPANY (LIMITED),

27, LEADENHALL-STREET, LONDON.

JOHN SMITH & Co.,

ENGINEERS AND BOILER MAKERS,

Sole London Agents.

All Boilers supplied by this firm Insured the First
Twelve Months Free of Charge.

NEW WORKS PUBLISHED

BY

E. & F. N. SPON,
16, BUCKLESBURY.

Just published, 8vo. cloth, price 18s.

PRACTICAL SPECIFICATIONS of WORKS
executed in ARCHITECTURE, CIVIL and MECHANICAL
ENGINEERING, and in ROAD-MAKING and SEWERING: to which
are added a Series of practically useful Agreements and Reports.
By JOHN BLENKARN, Civil Engineer and Architect.
London: E. and F. N. Spon, 16, Bucklersbury.

Royal 32mo. roan, price 5s.

**A HANDBOOK FOR ARCHITECTURAL
SURVEYORS,** and Others Engaged in Building.
By JOHN THOMAS HURST, C.E.

CONTENTS.

Formulae useful in Designing Builders' Work.
Tables of the Weights of Materials used in Building.
Memoranda connected with Builders' Work.
Architectural Mensuration.
Constants of Labour.
Valuation of Property.
Summary of the Practice in Dilapidations.
Scale of Professional Charges, for Architects and Surveyors, with
various useful Tables and Memoranda.

London: E. and F. N. Spon, 16, Bucklersbury.

Just published, elephant folio, cloth, price 22 1/2s.

Kept also in Limp Binding at the same price (can be rolled up in a
compass without injury to the plates).

**PRACTICAL ILLUSTRATIONS of LAND
AND MARINE ENGINES,** showing in Detail the Modern
Improvements in High and Low Pressure, Surface Condensation,
Superheating, together with Land and Marine Boilers.

By N. P. BURGH, Engineer.

London: E. and F. N. Spon, 16, Bucklersbury.

Royal 32mo. roan, 4s. 6d., post free.

**RULES for DESIGNING, CONSTRUCTING,
AND ERECTING LAND AND MARINE ENGINES and
BOILERS.**

By N. P. BURGH, Engineer.

London: E. and F. N. Spon, 16, Bucklersbury.

Eighth Edition, in royal 32mo. roan, price 4s. 6d., post free.

**A POCKET BOOK of USEFUL FORMULAE
AND MEMORANDA,** for Civil and Mechanical Engineers. By
GUILDFORD L. MOLESWORTH, Memb. Inst. C.E.
London: E. and F. N. Spon, 16, Bucklersbury.

Just published, on a Sheet, price 1s.

**DELANY and OKE'S WAGE TABLES for
ENGINEERS, SHIP-BUILDERS, CONTRACTORS, BUILDERS,
&c.,** from a quarter of an hour, in regular progression, to nine hours
and three-quarters, and from one day to ten days, at 1s. to 8s. per
day.

London: E. and F. N. Spon, 16, Bucklersbury.

Just published, royal 8vo. price 7s. 6d.

**THE SEWING MACHINE: Its History,
Construction, and Application.** Translated from the German
of Dr. HERBERT, by UPFIELD GREEN. Illustrated by Seven
large folding Plates.

London: E. and F. N. Spon, 16, Bucklersbury.

600 pages, crown vo., price 10s. 6d.

PERPETUAL MOTION. Its History during
Three Centuries; with ample Descriptions and Illustrations.
By HENRY DIBBEK, Civil Engineer.

London: E. and F. N. Spon, 16, Bucklersbury.

Royal 8vo., cloth, illustrated with 41 Plates, price 16s.

**A PRACTICAL TREATISE on the SCIENCE
of LAND and ENGINEERING SURVEYING, LEVELLING,
ESTIMATING QUANTITIES, &c.,** with a General Description of the
several Instruments required for Surveying, Levelling, Plotting, &c.
By M. S. MERRITT.

London: E. and F. N. Spon, 16, Bucklersbury.

Just Published, royal 8vo., half-bound, illustrated by 84 Plates of
Furnaces and Machinery, price 32 1/2s.

**THE IRON MANUFACTURE of GREAT
BRITAIN,** Theoretically and Practically Considered; including
Descriptive Details of the Ores, Fuels, and Fluxes employed; the
Preliminary Operation of Calcination; the Blast, Refining, and
Fining Furnaces, Engines and Machinery, and the various Pro-
cesses in Union, &c. By WILLIAM TRUBAN, C.E., formerly En-
gineer at the Dowlais Iron Works, under the late Sir John Guest,
Bart., subsequently at the Herwall and Forests Works, under Mr.
Crawshaw. Third Edition revised from the Manuscript of the late Mr.
Truban. By J. Arthur Phillips, Author of "A Manual of Metallurgy,"
"Records of Mining," &c., and W. H. Dornan, C.E.

London: E. and F. N. Spon, 16, Bucklersbury.

Just Published, post 8vo. cloth, 2s. 6d.

**MEMOIRS of the DISTINGUISHED MEN OF
SCIENCE OF GREAT BRITAIN, LIVING A.D. 1807-8.** By W.
WALKER, Jun., with an Introduction by Robert Hunt, F.R.S.
Second Edition, revised and enlarged.

Containing the lives of Watt, Rennie, Telford, Mylne, Joseph
Chapman, Murdoch, the first to introduce gas into practical use;
Rumford, Huddart, Boulton, Brunel, Watson, Bentham, Maudslay,
Dalton, Cavendish, Sir Humphry Davy, Wollaston, Hatchett, Henry,
Allen, Howard Smith, the father of English geology; Croxson,
inventor of the Spinning Mule; Cartwright, Tennant, Ronalds,
the first to successfully pass an electric telegraph message through a long
distance; Charles Karl Stanhope, Trevithick, Nasmyth, Miller,
of Daleston, and Symington, the inventors and constructors of the
first practical Steam Engines; Professor Thomson, of G.E., formerly En-
gineer, Donkin, Congreve, Herschel, Maskelyne, Baily, Fotherham,
Lenie, Playfair, Rutherford, Dollond, Brown, the Botanist; Gilbert
and Banks, the Presidents of the Royal Society at that epoch of
time; Capt. Kater, celebrated for his pendulum experiments; Dr
Thomas Young, and James, the inventor of manikind; Jas. Ivory,
Dr. Priestly and Cort, the father of the Iron trade.

London: E. and F. N. Spon, 16, Bucklersbury.

UPFIELD GREEN,

JOINERS' HALL BUILDINGS, 79, UPPER THAMES STREET, E.C.,

LITHOGRAPHER, PRINTER, ARTIST, AND DESIGNER,

PLANS, DESIGNS, SPECIFICATIONS, AND EVERY DESCRIPTION OF ENGINEERING DRAWINGS EXECUTED WITH RAPIDITY AND ECONOMY.

Estimates Forwarded for All Kinds of Turf Clocks.

Estimates Forwarded for All Kinds of Turf Clocks.

GOLD FROM 1 GUINEA.

SILVER FROM 1 GUINEA.

"EXCELSIOR," "EXCELSIOR"

Family Sewing & Embroidering Machine

WITH ALL THE LATEST IMPROVEMENTS.

IS easy to operate, simple to learn, quiet in action, and not liable to derangement. It will TUCK, HEM, FELL, GATHER, CORD, QUILT, BRAID, and sews from two ordinary reels, requires no re-winding, and the seam, if cut at every inch, will not rip. Price from £6 6s.

WHIGHT AND MANN, 143, HOLBORN BARS, LONDON.

MANUFACTORY—GIPPING WORKS, IPSWICH.

PRICE LISTS FREE.

Crickmer's Patent Plastic Metallic Packing.

FURTHER REDUCTION IN PRICE ON AND AFTER OCTOBER FIRST.
PATENT WIRE GAUZE JOINT PACKING... 1s. 6d. per lb. INDIA-RUBBER CORE PACKING (HEMP)... 1s. 4d. per lb.
CRICKMER'S PATENT PACKING... 2s. 3d. Do. Do. (COTTON)... 2s. 6d. Do.
This Packing takes less Tallow to lubricate it than any other, and being a Pliable Metallic Surface, requiring but little Pressure to keep it Steam tight, there is a great saving in friction.
PATENT TALLOW PUMPS AND LUBRICATORS.
WELL STRETCHED LEATHER MILL BANDS, HOSE PIPES, FIRE BUCKETS, VALVES, WASHERS, &c., &c.
CAUTION.—Engineers, Millowners, and others are Cautioned against Purchasing a Spurious Metallic Packing, purporting to be Crickmer's. THE GENUINE CAN ONLY BE OBTAINED FROM

ALEX. ROSS AND CO., GRANGE ROAD, BERMUDSEY, or their Authorised Agents. Price Lists upon application.

H. WATTS,

MANUFACTURER OF IMPROVED OPEN AND CLOSE FIRE

KITCHEN RANGES,

ENGINEER,

HOT-WATER BATH APPARATUS ERECTOR,

1, Water-street,

NEW BRIDGE-STREET,

BLACKFRIARS, E.C.

Estimates sent, post-free, on application.

No Fitter or Turner should be without a Straight-edge.

The most reliable tool of this kind, graduated to the Standard Measure of the Realm, and manufactured with MARVELLOUS ACCURACY, may be obtained of

RICHARD LLOYD, MILL AND MACHINE IRONMONGER 135, STEELHOUSE LANE, BIRMINGHAM.

Clubs of Workmen supplied at reduced prices. No equal tool is sold under FOUR TIMES THE PRICE.

CHANGE WHEELS FOR SCREW-CUTTING LATHES.

NOTICE TO INVENTORS.—Office for Patents, 4, Trafalgar-square, Charing-cross. Printed instructions (gratis) as to the Cost of PATENTS, for Great Britain or foreign countries. Advice and assistance in disposing of or working inventions. Branch offices and agencies in every Continental State and in America. Established 30 years. Full information as to expired or existing Patents at home or abroad. Apply personally or by letter to Messrs. PRINCE and Co., Patent Office, 4, TRAFALGAR-SQUARE, CHARING-CROSS, W.C.

TO CONTRACTORS, ENGINEERS, SHIP BUILDERS, COLLIERY OWNERS, &c.—Sections and Prices forwarded on application for Boiler, Bridge, Boat, and Ship Plates, Angle, Tee, Beam, Girder, and Dock Iron of all sizes; Sheet Iron, Plate, Corrugated, or Galvanised; Wire Ropes for drawing, telegraph, or fencing; Black or Galvanised. Wire Ropes; Permanent, Colliery, or Tram Rails; Hoop Iron, Bar Iron, Nail Rods, Split Nut Iron, Gutter, Bevelled, Taper, Convex, Half Round, Sash, Tyre, and all descriptions of Fancy Iron; Bar Iron of all sizes; Wrought Iron Forgings, Castings, and Railway Material of every description.

JOHN HORSLEY, Iron Agency Office, 2, ST. ANN'S SQUARE, MANCHESTER.

PLANS, ELEVATIONS, &c., Made, Copied, Traced, Reduced, or Enlarged, in the best manner, at moderate charges, by J. J. GREENE, 63, Upper Stamford-street, Blackfriars.

THE LENOIR GAS ENGINE.—A number of these useful and economical engines to be seen in actual work in town and country. Being free from all danger, they can be used where steam power is totally inadmissible. Exhibition, and every information supplied at 40, Cranborne-street, Leicester-square, W.C.

THE LONDON DRAWING ASSOCIATION for supplying Engineering, Mechanical, Architectural, and General Drawing, Designs, Maps, Plans, Tracings, Wood Engraving, Electrotyping, 7, Duke-street, Adelphi, London. Enclose stamp for prospectus.

JOHN SHEPPARD, of 10, Marsden-square, Manchester, has specially adapted himself for the supply of ENGINE-CLEANING WASTE, at the following prices: Waste at £32 per ton; grey, £25 per ton; coloured, £21 per ton. Washing Material, for wadding manufacturers, at equally low prices, in bleached, crimson, grey, and black. Liberal terms to suppliers.

TO INVENTORS.—GENERAL PATENT OFFICES.—L. de FONTAINEMOREAU, 4, South-street, Finsbury, London; 19, Rue de la Fidélité, Paris; 32, Rue des Minimes, Brussels. Provisional protection, £7; to complete patent, £30; French patent, £6 10s.; Belgium, £2 10s. Circular gratis on application.

W. LANGTON'S PATENT SELF GENERATING GAS STOVE

BOILS or Frys by Methylated Spirits generated into Gas, free from smoke or smell, and is the most useful and economical invention for the purpose ever offered to the public.

Sold by all Ironmongers, and at the Manufactory, 36, CHARLES-STREET, HATTON-GARDEN.

To Electricians.

GAS CARBON (not compressed) Cut in Plates or Blocks for Batteries. Price Lists, on application with stamped envelope. P. HENDERSON, 3, Park-hill, Clapham, Surrey.

THE IMPROVED LEATHER DRIVING STRAPS FOR MACHINERY are stronger for a given weight, more effective, more durable, and cost considerably less than any other kind of Driving Belt. Special Straps for Portable Engines. Price Lists free.

Turner's Patent Strap and Hose Company. Manufactory, Armit Works, Greenfield, Manchester. Warehouse, 31, Mark-lane, London, E.C. Mr. H. FERRABEE, Agent.

INVENTIONS PROTECTED BY PATENT OR REGISTRATION, at fixed and most moderate charges. The Inventors' Manual free by post, or gratis on application.—Apply to Mr. BREWER (late Barlow and Co.), 89, Chancery-lane, London, W.C. Established 21 years.

INVENTORS ASSISTED

IN Securing, Carrying Out, and Disposing of their Inventions.—Apply to Messrs. B. BROWNE and CO., British and Foreign Patent Office, 49, King William-street, London-bridge.

A Pamphlet gratis, on Cost of Patents, may be had on application

INVENTIONS secured by Patent or Registration, on moderate terms, by application to Mr. WILLIAM BROOKES (of upwards of 25 years' experience in such matters). British and Foreign Patent Agency, 62, Chancery-lane, London, W.C.

PATENTS FOR INVENTIONS.—Full instructions may be obtained by applying to Mr. W. T. RAWLE, Office of British and Foreign Patents, 3, Small street, Bristol.

NEW AND ORIGINAL SCIENTIFIC WORK

Now Preparing for Press, and will shortly be Published, Size Sixteen Quarto Pages, Illustrated,

The Mirror of Science:

A Weekly Miscellany of Entertaining and Instructive Articles on

PHOTOGRAPHY, CHEMISTRY, ELECTRICITY, ASTRONOMY, &c., &c.,

Price Twopence (Weekly).

PUBLISHING OFFICE, 147, FLEET STREET.

COMMUNICATIONS TO THE EDITOR TO BE ADDRESSED TO 75, FLEET-STREET.

PATENT HOLLOW STEAM PACKING.

THE great and peculiar advantages of this packing consist in its remaining perfectly elastic, and is so constructed and applied that the pressure of the steam itself makes the joint by entering the packing from the cylinder; thus the many objections to packing previously existing are effectually removed.

Vulcanised India-rubber Sheet Washers, Valves, Springs, Hose, Glazed and Solid Tubing for Gas, Speaking Tubes, Diving Dresses, Gas Bags, Air-proof Goods, or any description of India-rubber articles made to order.

Price list or circular, with full description of packing, to be had of the only Manufacturers and Patentees of Hollow Steam Packing.

FOSTER and WILLIAMS, India-rubber Works, Cowper-street, City-road.

W. JONES,

DIE SINKER.

EMBOSSER AND ENVELOPE MAKER, MACHINIST,

PRESS AND BRASS LABEL MANUFACTURER, 246, HIGH HOLBORN.

TO ENGINEERS (Civil and Mechanical), Patent Agents, Inventors, Architects, Builders, Iron Founders, &c.

Patterns for Castings, Models for Locomotive and other Engines, Ships, Carriages, Bridges, Permanent Way, and every description of Machinery made to order, Templates, Working and Finished Drawings, Turnings, &c. Models, and Plans for Trials.—New Inventions practically carried out full size or to any scale. Iron, Brass, and Malleable Iron Castings supplied, by **MAGDOREAN & Co.**, 140, Salisbury Court, Fleet-street, E.C. Agents for L'Esclapart's Patent Gas Engines.

N.B. Prospectuses and space papers for the City of London Working Classes Exhibition, and all information given.

W. R. GIBSON,

DRAUGHTSMAN AND ENGRAVER ON

WOOD, LITHOGRAPHER, &c.

EAST TEMPLE CHAMBERS, WHITE-

FRIARS STREET, LONDON, E.C.

THE EVAPORATOR SURFACE CONDENSER (PERKINS'S PATENT).—This simple apparatus, having now been in use for some years, can be strongly recommended as very effective and economical.

A vacuum of 26 in. can be readily obtained by evaporation alone, and all the water now required for the ordinary condenser is dispensed with entirely, and pure water is returned to the boiler, thus avoiding all sediment, &c. In non-condensing engines the water is returned to the boilers at a temperature of 212 deg.; and, by the addition of a donkey air-pump, all the advantages of a condensing engine is obtained.

ECONOMIC LUBRICATOR,

FOR MARINE, LOCS, AND FIXED STEAM-ENGINES.

(As supplied to the Admiralty, and many Engineering and Steamship Companies.)

This Lubricator offers a perfect method of lubricating all the internal parts of the steam-engine, by the vaporisation of the lubricant, saving, at least, half of the oil or tallow generally used, and lessening the "wear and tear" consequent upon imperfect lubrication.

PRICES, COMPLETE, WITH GUN-METAL FITTINGS:—

2 Pints, 62s. 6d.; 3 Pints, 67s. 6d.; 4 Pints 75s.

BRIGHT GUN-METAL BODIES, EXTRA.

As they are fixed on the steam-pipe, the diameter of this should be given; and it should also be stated whether horizontal or vertical.

BRITISH AND FOREIGN PATENTS AND THE REGISTRATION OF DESIGNS.

MR. H. H. MURDOCH having succeeded to the business of his late Father, which has been established upwards of Thirty Years, offers his professional services to inventors. A circular, containing full information respecting the various modes of securing protection for inventions at home and abroad, may be had, Gratis, by applying (personally or by letter), at his OFFICE FOR PATENTS, 7, STAPLE INN, LONDON.

PATENTS.

MR. VAUGHAN, Member of the Society of Arts, British, Foreign, and Colonial Patent Agent, 54, Chancery-lane, W.C. Transacts every description of business connected with Letters Patent for Inventions. Provisional protection, 5 to 8 guineas. A "Guide to Inventors" free by post.

ENGLISH MECHANIC:

A Record of Mechanical Invention, Scientific and Industrial Progress,
Building, Engineering, Manufactures, Arts, &c.

Vol. II.—No. 33.]

FRIDAY, NOVEMBER 10, 1865.

[PRICE ONE PENNY.]

COOLING AND FREEZING.

Our readers have at various times asked us for an illustration of the machinery used for these purposes. We have now the pleasure of complying with their wishes. The apparatus is styled "Brooman's Cooler and Freezer," and is founded on a communication to him from Marcar Beyli'h, of Constantinople. The apparatus, which the inventor denominates "psychrogene," produces artificial cold by the vaporization of a volatile fluid, the same quantity of which may be used over and over again. The congealing receiver partakes of two special forms dependent upon the ice to be produced.

The accompanying illustrations shew the combination of parts constituting this new apparatus.

u, opening upwards, and guided by a vertical rod. Upon the opening *m* of the mercury well a compartment *o* is fixed, where the valve *u* slides with very slight friction; at the upper part of this compartment there is a cup *p*, in the centre of which there is a bi-conical opening for receiving on one side the valve *u*, and on the other the body of the valve *q*, which is pressed by a coiled spring. The cup *p* is pierced laterally with a circular opening, in which a solid piece of glass *r* is hermetically fixed. *s* is the pressure chamber; to its upper part a cylindrical tube is screwed, and at its lower part, which is conical, rests the suction valve *u*, which is in the centre of the valve *q*, and in this manner the orifice of this latter is in communication with the compart-

ment *o*. The pressure chamber *s* terminates laterally in a tubular branch *t*, covered by a second valve without spring *u'*; *v* is a pipe uniting the ejection chambers; and *z* is a pipe uniting the suction compartments. *A* is the receiver of the condenser, surmounted by a series of a tinned iron tubes surrounded with fine cambric, the rows of stitches of which are folded in loose nets; the upper ends of these nets traverse caoutchouc tubes, which dip in the reservoir *B*; it is furnished with a cock *C*, from whence runs the conducting pipe *D*, which places the interior of the condenser in communication with the pressure chamber. The box *e*¹¹, annexed to the condensation receiver, encloses a bath with a thermometer filled with alcohol, and is pierced with two openings *f*¹¹ and *g*¹¹, the one of which receives the discharge tube *h*¹¹, communicating with the inside of the feed cock (see Fig. 1), and the other

twelve atmospheres; there is also a level gauge *u* fitted to the box *e*¹¹. *J* is a fan chamber open upon the plan of a centrifugal fan; *k*, *k*, are the blast pipes, the arrows in which indicate the direction of the current; *E* is a tubular steam boiler, in the dome *F* of which the steam generated is stored. In the centre and upper part of this dome a bath with a thermometer *c*¹, filled with alcohol, is suspended to free the vapour of any drops of liquid carried off mechanically. The opening *d*¹ is for receiving the body of a vacuum and pressure gauge *e*¹ marking up to 12 atmospheres; *f*¹ is an opening, which is carried through the tube *g*¹ in the bottom of the boiler, and in communication with the discharge opening of the feed cock; *h*¹ is the body of a cock

Figure 1 is a vertical section of the whole apparatus; Figure 2 is a plan of the condenser; Figures 3, 4, and 5 shew in elevation and plan the congealing receiver.

a is a piston, the working surface of which is hermetically closed by the leather *b*; the connecting rod *c* is united to the crank *d*; *e* is the cylinder fixed upon the base of the water reservoir *e*¹¹; one end of the bent tube *f* is fitted to the side of this cylinder, while the other end is united to the cylindrical piece *g* of large diameter; the bent tube is provided with a safety valve *b*, the orifice of which opens in the water reservoir. The cylindrical piece *g* is screwed upon the opening *i* of the mercury piston *j*, leaving at the point of junction circular cavities *h*¹¹, *h*¹¹, the section of which is in the form *z*. The cylinder *g* receives the moveable cover *l*, the rod of which slides in a ring. The conical opening *m* of the mercury well receives the body of a valve

ment *o*. The pressure chamber *s* terminates laterally in a tubular branch *t*, covered by a second valve without spring *u'*; *v* is a pipe uniting the ejection chambers; and *z* is a pipe uniting the suction compartments. *A* is the receiver of the condenser, surmounted by a series of a tinned iron tubes surrounded with fine cambric, the rows of stitches of which are folded in loose nets; the upper ends of these nets traverse caoutchouc tubes, which dip in the reservoir *B*; it is furnished with a cock *C*, from whence runs the conducting pipe *D*, which places the interior of the condenser in communication with the pressure chamber. The box *e*¹¹, annexed to the condensation receiver, encloses a bath with a thermometer filled with alcohol, and is pierced with two openings *f*¹¹ and *g*¹¹, the one of which receives the discharge tube *h*¹¹, communicating with the inside of the feed cock (see Fig. 1), and the other communicates with a pressure gauge marking

on which the suction pipe *I* is fixed, and through which the pumps take their supply; *j* is the level indicator gauge; *G* is the vertical section of the feed cock, the base of which *h* is pierced with two bent conduits, into which the ends of the tubes *g* and *m* are introduced laterally. The upper orifices of the bent conduits are covered with sheet lead, which is soldered to the base *h* and *g* pressed by the cylindrical piece *o*¹. Upon it rests the pointed end of a forked bar *p*¹, the arm of a lever *q*¹ charged with a weight *r*¹, resting upon the forked bar, the cylindrical piece *o*¹ presses the sheet of lead upon the base *h* so as to close communication between the tubes *g*¹ and *m*¹; the ring *s*¹, moveable upon its screw thread at the end of the lever, is traversed by a rod *t*¹, furnished at bottom with a button *u*¹¹, and joined at top to the carriage *r*¹, which is free to slide or to remain fixed by a screw upon the crank *x*¹ when the shaft of the toothed wheels receives its

motion from the fly wheel shaft through a belt and the pulley Z, the rod P, moved by the crank, slides in the ring A, but when the button abuts against the end of the lever arm Q, it rises to travel with the rod, and ceases to press the cylindrical piece of against the sheet of lead; the elasticity of this latter yielding to the power of the compressed vapours, moves from the base upon which it was applied by the action of the lever, the small valve opens, whereupon communication takes place between the two lateral conduits; the play of the cylindrical piece of being limited in the space in which it is placed, the sheet of lead can only move a very slight distance from the base. When the crank reaches the position in which it no longer supports the lever, the sheet of lead compressed by the existing power becomes again placed upon the base, and passage by the cock is immediately shut off; by changing the position of the button M upon the rod, and of the carriage R upon the crank, the duration of the action of the cock may be varied at will. Among the outside parts shewn in the drawings there is the fly wheel H and the fan J, which drives the air through pipes K, K, around the pipes T of the condenser A; H is the framing which encloses the generator and condensation receiver N.

To explain the action of the apparatus: the mercury well j, the compartment a are filled with fine mercury, the maximum level of the mercury is designated by + upon the cup p, and the lowest level in the cylinder g by —, the piston a is driven into the water, whereby the interior of the pump is entirely filled to the exclusion of a single air bubble. To follow the working of the apparatus it will suffice to follow the action in one of the pumps, all being identical in the other. When the piston a at first at the bottom of its stroke is raised by the crank, it draws after it the column of water in contact with it. The column of mercury forms a continuation to the column of water, sinks in the chamber o, rises in the cylinder g, and takes the place of the water displaced, as this latter does that of the piston. A vacuum tends to be produced above the level of the mercury lowered in the chamber o, but thereupon the tension exercised in the generator opens the suction valve u, and enters the space occupied at first by the mercurial column. Equilibrium is established, and when the crank is at the top of its course the piston descends, presses upon the column of water, the water on the mercury and this latter compresses in turn the vapours, which are prevented returning into the chamber of the generator, the suction valve being closed. It becomes more and more compressed until its elastic power overcomes the pressure in the compression chamber, and raises the valve q, which remained closed during the first course of the piston. When the piston reaches the lowest point of its course, the elevation of the mercurial column attaining its highest point, the vapours entering through the generator are completely expelled into the compression chamber. At the second stroke of the piston the same effects are produced, and so on in the two pumps. When the tension in the compression chamber is sufficiently powerful to raise the valve w, the compressed vapours enter continuously into the condenser. By the employment of a mercurial piston absolute and permanent tightness is obtained in the moveable surfaces directly in contact with the vapours. However, for the success of this description of pump certain mechanical arrangements which will be cited are indispensable. The movement of the mercurial piston from a certain molecular motion is not so regular as that of a solid piston, especially when the diameter of the pump is great, and the to-and-fro motion rapid. The arrangements adopted prevent the jumping of the mercury, and control its level every instant a small quantity of mercury penetrates into the cavity n, and tends to destroy any injurious space. The object of the circular cavities h¹, h², is to prevent the water passing by sliding upon the slides of the cylinder g.

[We are sorry that lack of space compels us to delay the remainder of the explanation till our next number.]

Tides are affected by the state of the atmosphere. At Brest the height of high water varies inversely as the height of the barometer, and rises more than eight inches for a fall of half an inch of the barometer. At Liverpool a fall of one-tenth of an inch of the barometer corresponds to a rise of the Mersey of about an inch; and at the London Docks a fall of one-tenth of an inch corresponds to a rise in the Thames of about seven-tenths of an inch.

HERODOTUS refers to a petroleum spring at Zante, and it is said that the oil was used for burning at Agrigentum in Sicily.

ANSWERS TO CORRESPONDENTS

SPIRITUAL MECHANICS.—Two letters are lying at our office for the enquirer in this matter. They will be forwarded to him when address received.

J. M. S.—Your letter having reached us (from the publisher) mutilated, will you kindly forward us another for insertion.

C. LUCHEURST.—Thanks for your letter. The one inserted covers your ground.

GEORGE JOHNSTON (Ashley).—If you send to Mr. Woodcroft, at the Patent Office, he will forward you the specification at its price.

JOHN PALMER.—We don't think Lloyd's will insure under the circumstances. It is understood that officers generally are not insured; in fact, we believe they must be, to comply with the particulars of insurance.

J. D. E.—Thanks for your letter. You have been anticipated, and satisfactorily. Your query in another column.

JOSEPH HAGG.—Send a stamp and your address to Wale, Holborn; Lockwood, Stationers Hall Court; and Spon, Bucklebury, and they will forward you their catalogues. You will find it in one of them, we think.

A NOTTINGHAM MECHANIC.—Thanks for your letter. What has been given has been asked for by very many. What you require will shortly be started again. There is an E. Hott in 475, Oxford street; you might send there, but we don't know of the book you mention.

J. W. W.—Send to Spon's, Bucklebury.

E. ADAMSON.—It would meet with a certain amount of sale, provided you were in business, and had the means of pushing its sale along with other things. In that case, it would be worth while patenting. We question if it would under any other circumstances be worth more than trying a "provisional protection," and endeavouring to sell your right.

J. L. HAMPTON.—Tredgold's is a capital work; also Fairbairn, on millwork. Send to Spon's, Bucklebury.

J. H. W. G.—We will endeavour to get what you want.

S. F. FURNER (Caisley).—A humbug. Have nothing to do with it.

FRED HARDY.—An engraving of a design for a velocipede will appear in our columns next week.

R. B. W.—Thanks for the trouble you have taken.

PHILANTHROPOS.—Thanks; the hit will be borne in mind.

AGATE.—I. We will enquire for you. 2. We had often been asked for the memoir, and it appears to give great satisfaction to our subscribers.

. We have to ask our correspondents to sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have ten by the thousand; the same with "Well Wisher," &c. If they don't like to see their own names paraded, use those of an ancient or any other man.

Several letters remain over till next week for answer. LETTERS applying for information to be furnished by post cannot be attended to.

Correspondents are requested to keep copies of their drawings and manuscripts as the Editor cannot undertake to return such as may be rejected.

ROYAL SCHOOL OF NAVAL ARCHITECTURE.—On Monday last the winter session of the Royal School of Naval Architecture and Marine Engineering at South Kensington, in connection with the science and Art Department of the Committee of Council on Education, was opened, Mr. C. W. Merrifield, F.R.S., having been appointed principal in the room of Mr. H. J. Parkiss, B.A., who was drowned a few weeks since while bathing in the Cam. The course of study, which is calculated to last three years, consists of pure mathematics, applied mathematics, theory of fluid and resistance of waves, theory of design, construction and behaviour of ships, theory of steam and of design, and construction of steam engines, practical construction of ships, naval equipment, naval artillery, &c. In the course of the present month, four free studentships will be given in competition if qualified candidates come up, and to the two best of these scholarships of £50 per annum. The subjects of the competitive examination, with the number of marks attached to each, will be as follows:—1. Pure mathematics, including arithmetic, geometry, plain and descriptive; trigonometry, and the elements of the differential and integral calculus, 2,500 marks; 2. Theoretical mechanics or applied mechanics, 1,000 marks (in these subjects at least half the marks will be required); 3. Practical mechanics, 750 marks; 4. Practical shipbuilding; 5. Steam; 6. Physics; 7. Chemistry; 8. Mechanical and freehand drawing, 750 marks.

SOUTH-EASTERN INDUSTRIAL EXHIBITION.—This exhibition, which opened on Saturday week at Greenwich Hospital, has since been visited by an average number of 1,400 persons daily, and promises to be entirely successful. It is our intention to publish an extended notice of the mechanical department, in a future number of THE ENGLISH MECHANIC.

THE red, green, blue, and yellow colours have been successfully rendered by means of photography by Mr. Niepce de St. Victor.

NOTICE TO ADVERTISERS.

ADVERTISERS in this journal are respectfully informed that the Collector from the office, 162, Fleet-street, will call upon them for a settlement of the amounts due for the insertion of advertisements. The Collector will in every instance hand in a printed receipt for the sum paid to him. Advertisers are particularly cautioned against paying money without receiving the printed receipt.

THE ENGLISH MECHANIC!

Just Ready, and now Publishing, the
FIRST VOLUME

of
THE ENGLISH MECHANIC,
A Record of Mechanical Invention, Scientific, and Industrial Progress.

UPWARDS OF ONE HUNDRED
ILLUSTRATIONS.

Handsomely bound, only 4s. 6d.; post free, 5s.
GEORGE MADDICK, 162, FLEET-STREET, LONDON,
and all Booksellers.

THE ENGLISH MECHANIC.

Every Tuesday, One Penny. Monthly Parts, 5d.
Now Publishing, complete, the First Volume.
. Title Page and Index, One Penny. Cases for binding, One Shilling and Sixpence.
It is solicited that all back Numbers be ordered at once.

All the early Numbers have been reprinted. It is therefore necessary that sets be made up at once, as there will be no further reprints owing to the great expense they entail.

162, FLEET-STREET, LONDON, and all Booksellers.

TO ADVERTISERS AND CORRESPONDENTS.

. In future all Advertisements and Communications for the Editor to be sent to
162, FLEET-STREET.

OUR MONTHLY PARTS.

Part 7 of THE ENGLISH MECHANIC, in coloured wrapper, is now ready.

Price 5d. only! Post free, 7d.

All back Nos. have been reprinted, and can be had direct from our Office, or through any bookseller.

TO ADVERTISERS.

As the ENGLISH MECHANIC addresses itself to the largest and most intelligent portion of the community, and is the only Paper of the kind established, it offers unusual advantages as an advertising medium.

All Advertisements should be sent to us not later than Friday.

The English Mechanic.

FRIDAY, NOVEMBER 10TH, 1865.

FILE CUTTING BY MACHINERY.

IT is not so very long since we were informed that hand-cut files would soon sell at high prices—for museums, and as curiosities; for that the file-cutting machine was about to take the trade upon itself, and convert file-cutters into workhouse tenants, or other sort of cast-off clothes. We demurred to the statement at the time, knowing that the machine, as at present constructed—rocker bed and all—could not do the best quality of work, and in many cases could not do it at a figure lower than that now paid to the hand worker. We have waited for the file that was to be equal to the old hand-made one, but have not yet seen it; and the feeling is rapidly coming over us that the file-making machine companies of Manchester and Birmingham are more anxious now to sell their machines than they are to make files. About the time of the starting of these companies a bad name was given to the Sheffield men—before the trial of the machines be it remembered,—that they

would flow up the factories, assume the men who worked therein, and generally throw a sufficiency of obstacles in the way of the work as to render it anything but profitable. Whether this "name" was put on the "dog" by those interested in getting up the companies, we know not—we hope not; but the name was given, and the coincidence is singular, and suspicious. Now as to the men not allowing the machine to work: thirty years ago Messrs. Turton and Sons—a well known name and brand, by the way—erected file-cutting machines at their works in Spring-street, Sheffield, and the men did not strike against it, but did the work the machine could not do; nor have they ever, so far as we are aware, done more against the machine than this. Eventually Messrs. Turton's machine was turned on to the scrap heap, as the best place for it. So much for the interference of the men, and the efficiency of the machine. Now, as to difference in cost of production. Referring to the prospectuses of these companies, it is stated that good file cutters earn from £3 up to £5 per week. What is the fact? The "flat bastard file—14 inches" is the leading article in the trade, and for these the workmen are now better paid than ever they were. These "bastards" are now paid 3s. 6d. per "dozen of thirteen," for cutting, and he is no ordinary workman who can turn out seven dozen a week—year's end to year's end. Now from these four-and-twenty shillings two have to be deducted for steel and lead, and repairing chisels, leaving the workman twenty-two shillings as against the £3 to £5! Were the workman to be paid at this latter rate there would be a fine chance, and a necessity, for the machine—if it could produce all the workman can, which it cannot. We should like very much to know what it does cost to produce files, of any name, by machinery, including wear and tear, and all the odds and ends of necessary items; and until we can get at this we cannot make the comparison complete. Further than by this—that manufacturers seem disinclined to laying down the new machinery—not, be it remembered, from fear of the handworkers, but having a wholesome dread of having to do as did the Messrs. Turton and Sons. It is just possible we may be wrong—only, by our present light, we don't think so. If any reliable figures, confirmed by actual experience, can be forwarded us, we shall be happy to give them the consideration and publicity they may deserve. J.F.H.

HOW TO CONSTRUCT AN ACHROMATIC ASTRONOMICAL TELESCOPE.

SIR.—The invention of the telescope and the microscope may be properly classed amongst the most important discoveries ever made. True, the steam-engine has done more for the social well-being of mankind; but no inventions have done so much to ennoble the mind with exalted views of the Creator of all things. By the aid of one, we find the most perfect organisations existing in the minutest form, invisible to the naked eye; the other reveals to us the infinite extent of creation, in the innumerable worlds existing throughout the immensity of space, and opens to our view wonder, beauty, and grandeur, of which we should otherwise remain ignorant.

The possession of a good telescope is a source of unpeakable pleasure of the purest and most intellectual character, and this my humble effort at endeavouring to popularise this noble instrument, is one of the most pleasing—knowing it to be an object worthy of any man's ambition; and ere I lay down my pen, I trust I shall have placed the possession of a telescope that will show Saturn's ring within the reach of even a working man's pocket.

I will now briefly describe the construction of a telescope of a power of 120—a power which will show the half-enlightened phase of Venus, the satellites of Jupiter, the rings and two or three of the moons of Saturn, the nebulae in Orion, the companion to the Pole Star, the components of most of the double stars, and also divide the quadruple star in Lyra, together with various other phenomena of equal interest. Its cost, if my directions are strictly attended to, will not exceed £210s., which is but very small compared to the price of one of the same power, if made by an optician, viz., £9.

The first thing required will be the lenses, which can only be obtained from Mr. J. T. Slugg, 214, Stretford-road, Manchester, a gentleman who has devoted the greater part of his life to the construction of cheap and perfect achromatic lenses; and a gentleman to whom the public I think are greatly indebted for his unceasing efforts to popularise the telescope by placing it within the reach of all classes. The object glass must be 23 inches diameter, and 36 inches focal length, and will cost £15s. The eye-piece is a *pancratic* one, and con-

tains three powers, viz., 80, 100, 120, and costs 12s. Both lenses are fitted into cells ready to be inserted into the tubes, and it is advisable not to remove them from their cells on account of their liability to get scratched. These will be carefully packed and forwarded to you on receipt of a Post-office order for £117s., payable to Mr. J. T. Slugg. You must next procure two tubes of brass or other suitable metal, which can be obtained at a small cost from any respectable ironmonger. One of these must be 31 inches long, and the diameter suitable to your *object-glass* or the larger lens, which has to be inserted. Before fixing in the *object-glass*, care must be taken to blacken the inside of the tube by a mixture of lamp-black and spirits of turpentine to prevent reflection.

The other tube must be 10 inches long and of a diameter suitable to your *eye-piece*. This must be blackened in a similar manner to the large tube, and after it is dry the *eye-piece* is to be fixed in the one end.

You have now the two parts of your telescope, and all that is required to complete it is to place them together in the following manner:—

Make a block of wood three inches long, and of a diameter *tightly* fitting the open end of your large tube; in the centre of this block you must make a hole in which your small tube will slide backwards and forwards, but not too easily. This should be turned in a lathe, and without you possess one, you should get a carpenter to make it for you, as the centre of the *eye-piece* must be in a direct line with the centre of the *object-glass*; and the smallest deviation in this respect will materially injure the working of your telescope. This block should also be blackened.

For a telescope this size it is necessary to have a stand which is very firm and steady, and I should advise my readers to obtain one direct from Mr. Slugg, who makes an excellent one suitable for the above telescope at 16s. 6d., for a home-made stand is at best but an unsteady affair.

This telescope is one which, as regards power, I strongly advise my readers to be content with, if they make it themselves, as although for a few shillings more you can have more powerful lenses, yet the difficulty of constructing them properly increases so much, that it is time and labour lost. And I am sure the most interesting views can be obtained with this telescope. Indeed, some of the most important discoveries have been made with telescopes of comparatively low power.

Although this instrument cannot be supposed to possess that exquisite finish and expensive workmanship which is required by the professional astronomer in making his observations, it will nevertheless be so exact and well made as that it shall give to the man who may possess an intelligent and enquiring mind, but limited means, "an opportunity of making himself practically acquainted with those wonders of the starry heavens revealed only by a telescope, which he would, perhaps, live and die without ever seeing, but for such an opportunity."

Once you have made your telescope you will find ample repayment by the glorious views it will reveal to you. I could and would willingly say more on this interesting subject, but space bids me conclude, and I fear I have already taken up too much space in our valuable journal, THE ENGLISH MECHANIC. But I trust that this short letter may be the means of inducing some of your readers to profitably employ a few spare hours in the study of this most interesting and inspiring science; and I feel they will soon enter into the feeling of the Psalmist in saying, "The heavens declare the glory of God, and the firmament sheweth His handiwork."

6, Old Jewry, London, E.C. R. B. WEGG.

P.S.—Should any reader require any further instructions I shall be most happy to communicate with him.

CHANCELL, an English captain, in 1554, first sailed into the White Sea, and this led to the building of Archangel and the commerce of Russia.

DR. BENCK JONES states that sugar is produced in fluids of the animal body by extreme cold, owing to deficient oxidation of the carbonaceous articles of food.

M. BUNSEN finds that pyrolusite exceeds bismuth in thermo-electric power, and copper pyrites possess the same quality in a still higher degree.

M. REGNAULT has succeeded in obtaining photographs with bromide, iodide, and fluoride of copper; the bromide proved the most sensitive.

MR. BOHN states that the mistletoe has precisely the same relation to its nutritive plant as a twig to its parent branch, or a graft to the stock.

LETTERS TO THE EDITOR

[We do not hold ourselves responsible for the opinions of our correspondents.]

ELECTRO-MOTIVE POWER.

Sir,—It appears to me that there is an immense mechanical motive power lying dormant in Electro Magnetism. We all know how great is the lifting power of an electro-magnet, even when influenced by a very small battery and weak current.

With this fact in view, wherein lies the difficulty of propelling ships by means of electro-magnetism, except the cost of battery power? I am not sure whether it would not be practicable to convert the ship herself into a galvanic battery by sheathing one side with copper and the other with zinc, insulating the sheathing from the ship by means of sheets of gutta percha. The galvanic action of salt water on so large a surface would generate a sufficient electricity to create very large electro-magnets of immense power. Two thick wires or rods carried through the sides of the vessel in contact with the copper and zinc would communicate with the electro-magnetic engine, of which there are various forms. I suggest two very large magnets laid horizontally with their poles opposite each other, with an armature attached to a crank working between them; the current would be changed at the instant of contact, and the engine would be adapted to drive a screw shaft. The battery power would of course increase in proportion to the size of the ship. Perhaps some of your readers may be able to turn my suggestion on to account. It is simply a question whether sufficient power can be obtained from the action of salt water on so large a surface as the whole area of immersion of a floating vessel. From minor experiments I have not the least doubt of it myself. Jno. TAWSE.

STEAM BOILER.

Sir,—In your number of November 3rd, Aspirant offers several objections to my boiler. He asserts that the boiler would be a very heavy one, and that the plan would only add strength to the weakest parts. The only increase of weight will be the hoops, and the increase of their weight will be but of little consequence. Strengthening the weakest parts is a great desideratum.

The fallacy in the next paragraph of his letter is mainly caused through my own neglect at not stating in my letter to your journal, that the design was intended for a boiler fired internally—in which case, I intended that the flues should be made on the same principle reversed, when the steel traps will be dispensed with and the thickness of the two plates of iron will be nearly equivalent in their superficial area and thickness as the ordinary lap joints. The plates can be made in size according to the power of the boiler, and judgment of the maker; but he will perceive that the greater the number of hoops the stronger will be the boiler. I prefer the four plates in place of one, as he suggests on account of the liability of having a defective plate if rolled entire. I have no objection to welded joints in boilers, except that rivetted joints are more reliable; for the risk of imperfect welding is greater than that of imperfect rivetting. ADRIAN NEISON.

OUR SUBSCRIBERS' NOTES AND QUERIES.

ASSAYING.—Would any reader inform me respecting the title and approximate value of a good book, treating upon assays of copper, silver, and lead minerals, wherein the method of assaying is clearly explained.—H. E.

ZINC TRAY.—What would be the cost of a zinc tray, 2ft. long, 1ft. broad, 4in. deep, painted, with an ornamental wire rail 3in. high, round top—designed for an uncovered fernery.—J. D. E.

WATCHWORK, &c.—Where can I purchase watch materials and lever clocks? Is there any way of bronzing lead urns? H. J. F. (Winchester).

BOILER CLEARER.—Where can I obtain a patent boiler cleaner?—JAMES NEWTON.

ELECTRICITY.—In a cylinder electric machine, might a condenser made of alternate sheets of shellac varnished tissue paper and tinfoil be placed in the stand, and if so, how should it be connected with the cylinder?—T. TROSBROD. [Your stamps have been returned. We do not undertake the forwarding; sent to Mr. Woodcroft, Patent Office, Chancery-lane, they will procure what you require by return of post.]

SPOTS ON ZINC.—How can I remove spots of grease from polished zinc plates without injuring the surface of the plate?—W. J. P.

CASTINGS.—What can I run small castings of various metal in? Plaster is the best I have tried, but it will not last more than three times.—B. G.

TOOLS.—How can a tool be fitted on a lathe to turn ram-rod and the like?—B. GUY.

PUNCHING WASHERS.—How can I punch washers so that washer and burr will leave the die freely with one stroke of punch, the washer to be complete?—W. PUNCHER.

HARDENING PLASTER.—How can I do this for moulding without stopping the setting of it?—GUSTAVUS.

COATING PILLS.—How can I do this, with sugar, similar to plum coating?—G. G.

WATCHWORK.—How are the wheels and pinions of watches made, and how the small screws blued?—HAGILT.

VENEERS.—Where can I obtain the narrow stringing used for inlaying with veneers?—COUNTRY NOTICE.

MICROSCOPE.—It is desired to raise to about 200 a small compound microscope, magnifying about 30 diameters; can it be effected by placing a second object-glass, enclosed in a tube within the focus of the one I now use, or what other arrangement?—And price of lenses?—G. T.

WINDOW SHOW.—How can I construct a machine to turn a stand and figure in a window?—SNIP.

OXIDATION.—How can I prevent this in steel after it has been highly polished, without affecting the lustre?—FARROW-BANK.

MAGNETISM.—How can I produce this in steel?—J. B. PLATINIZED SILVER.—Where can I obtain a plate of this, 6in. by 4in. wide, for a Smee cell, and its price?—W. H. H.

HEAT.—The simplest way of obtaining, equal in intensity to a potter's oven?—J. L.

STONE CUTTING AND POLISHING.—Where can I obtain information respecting these; or the price of any work on them?—J. L.

CAMS.—How to turn cams, with different lengths of dwell?—J. P.

TELEGRAPHY.—Where to purchase, and price of the work on telegraphy by Culley, of Bristol?—E. MCGURK.

FRETTING AND MOULDING MACHINES.—Can any one tell me of a book on these, where published, and price?—J. HERBERT.

VARNISH.—Can one be made from oilbarnum?—DABBLER.

(1) Use a good scrubbing-brush and sand.]

LACQUER.—Wanted, a good recipe for making green lacquer.—AMATEUR.

GRAVITY.—Wanted, to know how to find the centre of gravity in any solid body, a bit of wood for instance?—C. R.

FIRE.—Why does fire die out under the action of the sun?—F. MASON.

ANILINE GREEN.—Where can I get information respecting Simpson, Maule, and Nicholson's method of producing?—G. L.

POLAR AXIS.—Wanted the length, in feet, of the earth's polar axis; also the diameter of the equator of a circle, but if an ellipse, the length of the two principal diameters, in feet, with the longitudes of their positions. Captain Clark's (Memoirs R. Astronom., Soc., 1860) would be most satisfactory.—T. C.

FULHAM RAILWAY.—How is it getting on?—J. J. AYLING.

RUST ON WIRE.—How can I remove, without injury, rust from wire netted window blinds?—A. SMITH.

ELECTROTYPY.—How are plaster figures prepared for electrotyping?—F. B.

ENGRAVING.—Does any one know of a work on this art, and the tools?—H. GILBERT.

SHOEMAKER'S BENCH AND RIVETTING MACHINE.—Where can I see these, in or near to Birmingham?—S. L.

DRILLING.—I have a surface of cast iron to drill with 4,000 holes, 3-32 inch in diameter, through 3-16 inch stuff. Have tried every shape of drill, at all tempers? am beaten? can't make drills fast enough. Will any one help me in my quandary?—VULPES.

COVERED COPPER WIRE.

Sir,—Allow me to say that No. 35 B. W. G. copper wire, is under rather than over 1500 yards to the pound, and when covered with silk, if any amateur thinks he will get more than 1400 yards in the same weight, he is woefully mistaken. I know Silvers 35 wire very well, and the above applies to it.

Mr. Preece gives the diameter of No. 35 as .005; but it is not the B. W. G. 35.

You may call any gauge you please by any number you please; but I take my stand upon the B. W. G., and say the length is as above given; and if any one doubts my word, let him go to a Birmingham wire drawer, and get a pound, and test it for himself.

Since however, there is such an utter dissimilarity in different gauges, it would be desirable to abolish them altogether for fine wires; they are not to be depended upon for accuracy.

It is, doubtless, convenient in the trade to denote a particular size by a number which corresponds with some standard gauge, but it would be better to call all sizes of wires by their diameters; or, if this be found impracticable, it is a pity some standard gauge is not adopted.

But your correspondent found the diameter of his wire to be .005, and to measure, when covered, 108 yards to the ounce.

Mr. Preece also finds the same diameter for No. 35; but the weight of one mile of his is .4012 lb., or more than double the length of Mr. Williams's, the diameters being the same.

Now, in electrical experiments, accuracy is essential, and an amateur should know as near as possible what length he will get of a given number, and weights of covered copper wire, otherwise his experiments, calculations, deductions, and the rest, are worthless. 400 yards difference between your No. 35 and mine, my friend, is no joke; but you are a lucky dog it seems, and got No. 36 at No. 35 price. May very reader of these pages who want a pound of wire be equally fortunate.

S. TAYLOR.

HEATING, &c.

Sir,—In reply to Seghill.—For a house the size mentioned, he would be better supplied with hot water by having a tank, which he may place anywhere as near the boiler as possible, if it is six or eight feet above the boiler, to hold 40 gallons, and the boiler 30. The boiler to be supplied from the main cistern by 3 inch lead pipe, without any branches, and the boiler and tank to be supplied with strong 1 inch lead pipe. The hot from the boiler top, to underside of tank, and the return from the tank out at the side a little above the centre into bottom of boiler.

The tank is part and parcel of boiler, and, as the water commences to heat, so it revolves, the supply through the house to be taken from the top of the tank, and led away through a 3 inch lead pipe to the different branches, to be always on the ascension to the steam or safety pipe. For a main pipe he may use 1 inch pipe; but I think 3 inch inside is plenty.

If the house is not large, he may have plenty of hot water without a tank, with a boiler the same size, to be supplied in the same way from the main cistern, and branching off as before. The reason why there should be no branches off the supply to the boiler for fear that it might come to draw from supplying it, and there is a danger of a cock being left open, and then by endangering the boiler and life.

MORRE.

THROW OF VALVE.

Sir,—A. K. B. wishes to know what I mean by the throw of the valve. It is just equal to the travel of the slide. He also thinks there must be some mistake as to the letters G, I, F, but they are quite correct. Set the line G, I, F, at right angles to the crank, the same as in the diagram. The diagram will either do for engine with or without link motion. The throw of an eccentric is equal to twice the eccentricity of the inner circle keyed on the shaft.

JAMES MORRISON.

Sir,—In reply to Cagliostro, in No. 30, September 27th if he cannot find Beeton's book of "Parlour Magic," he may procure from almost any respectable bookseller, or for one penny additional, from the publishers, Messrs. Cameron and Co., Publishers, 88 and 94, West Nile-street, Glasgow, "Parlour Magic," price 3d., "Tricks and Delusions," with cards, 3d., "Whole Art of Magic," 6d., "Boys' Book of Magic," 1d.

D. MCCANN.

AIR PUMP PACKING.

Sir,—W. Taylor recommends a strip of bladder for the valve of an air pump; he will find a strip of oil silk much better, as it will not get hard and stiff like bladder, and thus prevent the free passage of the air.

F. HART.

Sir,—In answer to R. T. S., the simplest form of chuck for turning brass rods, &c., is this. A plain chuck of any metal (A) with a coned end, has four small wedges B, arranged in the form of a cross, and screwed into the end of the chuck. By making a crosscut in the end of the rod to be turned, the wedges B take into the crosscut and hold it effectually.

The quickest way to make a chuck of this kind is, I find to solder the wedges on a brass or pewter chuck. I have had such a one in use for turning iron and brass rods for years past. It is not my own invention.

T. E. MERRITT.

SIMPLE FURNACE.

Sir,—I am pleased to see my small furnace has given satisfaction to Amateur Mechanic. I think he might obtain a single crucible from Mr. Statham, chemist, 111, Strand, W.C. I think by attending to the following description and diagrams, Amateur Mechanic will be enabled to construct one for himself of a superior kind, and suitable for the furnace at a small outlay.

Two parts of fine ground raw Stourbridge clay, and one part of the hardest gas coke previously pulverized and sifted through a sieve (the coke must not be too fine, or the pots are liable to crack), mix with the proper quantity of water, and tread the mass well. The pot must be moulded on a wooden block, constructed similar to the following:—

A, the bench; C, B, two uprights supporting a cross bar C; D, the wooden block on which the pots are moulded, supported on spindle E, which turns in a hole in the bench; F, a gauge to regulate the thickness of the melting pot. He should also have a cap of linen placed wet on the core before the clay is put on to prevent it from sticking, and have a wooden ball to assist in moulding.

A pot thus constructed when wanted for use is first warmed by the fireside, and then laid in the furnace with the mouth downwards, the red coals being previously clamped with cold ones, in order to lessen the heat; more coke must then be thrown on till the pot is covered, and it is then brought to a red heat gradually. The pot must then be fixed mouth upwards in the furnace without being allowed to cool, and must be charged with cold iron; in a short time the iron will be melted (it must be so placed to be within a little distance of the top). A pot constructed thus will last for fourteen or eighteen meltings, provided it is not allowed to cool in the intervals. Should it be allowed to cool it will crack. The best plan is to allow it to cool gradually in the ashes.

Will some subscriber inform me how to construct a small set of figures to work by clockwork similar to those exhibited at Bristol.

EDWARD MCGURK.

1, Houndwell View, Southampton.

TELESCOPE, MICROSCOPE, AND BAROMETER.

Sir,—Satellite can scarcely be serious in enquiring how to get up a telescope with a "12 inch object glass, cheaply." Messrs. Merz and Son, of Munich, are probably the only opticians who would undertake a glass of such aperture, Messrs. Cooke, of York, might, but I am uncertain as to this, and they would certainly not let Satellite have it under a thousand, or more likely eleven hundred pounds. An eye tube with glass complete may be bought for a sovereign.

J. Whitehead may obtain Collins' Dissecting Microscope at 77, Great Titchfield-street, Portland-place, London; the price is two guineas.

Finally, in reply to Torricelli, there is no fixed proportion between the area, or rather bore, of the tube of a standard barometer and that of the cistern; and for the simple reason, that in all standard instruments the scale terminates downwards in a fine ivory point, which is always made to coincide with its reflected image in the mercury in the cistern before taking an observation by either raising or depressing the moveable bottom of the cistern. The scale of inches thus always starting from the surface of the mercury, there is no correction to be made for "capacity," and thus all need for knowing the relative areas of the tube and cistern is obviated.

AN AMATEUR TURNER.

Sir,—In answer to Torricelli, No. 31, I find there is no reason why the diameter of the cistern of a barometer should bear any ratio to the bore of the tube. The most approved standard barometers have a movable bottom to the cistern, to allow of adjusting the surface of the mercury to the zero of the scale. In making an immovable cistern, however, it would be advisable to consider the diameter (supposing the shape to be cylindrical), which will the least vitiate the reading of the scale, supposing it to be fixed. Let D = internal diameter of cistern; d = do. tube; B = range of barometer column; b = corresponding range of the surface of the mercury in the cistern. Now, the scale is only correct when b = o; which it never can be with a fixed cistern, however large. Taking the bore of the tube at 1/8 of an inch, B = 1 inch and b = 91 inch. We can calculate D as follows:—

Volume of B = $1 \times \frac{1}{8} \times \frac{1}{8} \times 7854$; do. b = $D^2 \times .01 \times 7854$. Since whatever mercury passes from the tube enters the cistern *et vice versa*, the volumes of B and b are equal. Hence, $D^2 \times .01 = \frac{1}{8} \times \frac{1}{8} \times 7854$; whence $D = 6\frac{1}{2}$ inches; rather inconveniently large. It would be better to have a smaller cistern with a movable bottom, or a small intact cistern, and apply a movable scale to the barometer.

In this calculation I have omitted to allow for the annular space occupied by the end of the tube, which dips into the mercury in the cistern, as it would have no appreciable effect upon the result.

RICHARD STRACHAN.

11, Offord-road, Barnsbury, N.

TELESCOPE.

Sir,—Satellite will find all he wants to know in "The Telescope, its Construction, and Use," by J. T. Slugg, Simpkin, Marshall, and Co., London. Price is 6d. A 12-inch achromatic object glass is an expensive affair. Let him make or buy a silvered glass speculum, and fit up a reflector. It will cost a great deal less, and be more pleasant to use.

OLD CHARLIE.

CHUCK FOR SMALL WORK.

Sir,—In answer to R. T. S., who requires a chuck for turning small brass rods, I think he will find this a very handy one:—

It consists of a chuck and eight screws; the chuck is hollow, the end being enlarged. If required, to screw on the mandril. Four screws are placed at one end at equal distances on the circumference from one another, and the other four are placed at the other end, equal distance from one another, and opposite to the spaces made by the other four. Holes are drilled through the ends of the screws to admit of being easily tightened.

G. S.

STEEL POLISH.

Sir,—The polish on flat-steel pieces in fine watch work is produced with oil stone dust, burnt Turkey stone, and a steel polisher, soft steel, bell metal, and sharp stuff, grain tin and glossing stuff. The metals are squared with a file, and vary in shape according to the work in hand.

E. Feather.—The oil recommended by Mr. Denison is neat's foot oil, well stirred about in water, skimmed off, and filtered once or more through blotting paper until it is quite clear. I never use any other than olive oil, and, by experience, I know that when pure, it is well suited for the purpose. Small emery sticks (so called in the watch trade) about three inches long, and small in the round are used for chamfering dial holes. I have tried to obtain and failed. Perhaps some of your readers will instruct me how to make, or where to obtain the same?

A LIVERPOOL WATCHMAKER.

AQUARIUM FOUNTAINS.

Sir,—In answer to W. Brown in your last number, I made a fountain in my aquarium in the following manner:—

I fastened on the wall near the ceiling a tin vessel, from that I carried a dead pipe one-eighth of an inch in diameter. I let that pipe go through the bottom of my aquarium, and then through the rock work. In the end of the lead pipe I fastened a piece of glass tube with a very fine hole, and about 1-64 inches in inside diameter, and I let that pipe finish just at the water surface.

PHILIP.

upon a perforated revolving plate over a charcoal fire, hardened in oil and blazed off. Next, the spring is distended in a metal frame, and ground and polished with emery and oil between lead blocks. At this point its elasticity seems gone, but this is quickly restored by hammering on a bright anvil. The colouring is done over a flat plate of iron, under which a spirit lamp burns: the spring is continually drawn backwards and forwards over this, about two or three inches at a time, until it assumes the orange or deep blue tint throughout as required. The last process is to coil the spring into the spiral form, which is done by a tool with a small axis and winch handle, and does not require heat. The balance springs of chronometers, in the form of a screw, are wound into the square thread of a screw of the appropriate diameter and coarseness; the two ends of the spring being retained by side screws; and the whole is carefully enveloped in platinum foil, and bound tightly with wire. The whole is then placed into a piece of gun barrel and heated, then plunged into oil, which, without discolouring, hardens the spring; the covering is removed, and the spring let down to the blue before removal from the screwed block. The hair springs of the best watches are hardened in

RAMSBOTTOM'S MANUFACTURE OF STEEL AND IRON.

This invention, patented by Mr. J. Ramsbottom, engineer, Crewe, is applicable to the manufacture of steel and iron by the atmospheric process commonly known as the Bessemer process, and as described in the specification of letters patent granted to Henry Bessemer on the 12th February, 1856, No. 356, and it consists in certain improved apparatus for heating atmospheric air or other gases before they are forced through the liquid metal in the converting vessel. The apparatus for heating the air or other gases may be constructed as shown at Figs. 1, 2, and 3, in the accompanying engraving.

Fig. 1 is a plan of part of an apparatus for converting iron into steel according to the Bessemer process above referred to.

a, a are sections of the converting vessels, which oscillate on the centres indicated by the dotted lines *b, b*; *c* is the foundation plate of the crane for supporting the ladle by which the molten metal is poured into moulds ranged round the semicircular wall *d*; *e* is the chest containing the valves for regulating the blast, and *f* is the series of pipes for conveying the blast or compressed air forward to the

*f*₂ of the pipe *f*, and are thence passed forward into the pipe *f*, the lid *f*₃ having been previously secured to the other end of the pipe; the lid *f*₃ is then secured, and the blast, in passing through the pipe *f*, becomes heated to the required extent before entering the converter. The relation between the heating surface and the quantity of heat contained in the spheres may be varied at pleasure, either by altering the diameter of the spheres or by making them hollow. When the blowing is completed the lid *f*₃ is removed, and the spheres are allowed to run out, or are blown out of the pipe *f* into a box, in which they are taken to the oven to be re-heated for further use. It is evident that the same spheres may be used for heating the blast of any convenient number of converters. The pipe *f* may be lined with fire-bricks or other non-conducting substances, so as to prevent loss from radiation and reduce the disturbances arising from expansion and also the reduction in the strength of the pipe from excessive heat, when the temperature of the air is required to be very high.

Fig. 4 represents a modification of the improved heating apparatus, *h* is a vessel lined with fire-brick or other non-conducting substance. At the top of the vessel is a manhole provided with the lid *h*, and

the coil on a plain cylinder, and curled into a spiral between the edge of a blunt knife and the thumb. Mr. Dent, in his lectures on the time-piece, stated that 3,200 springs weigh only one ounce; and as soft springs are worth 2s. 6d. each, and the hardened and tempered ones worth 10s. 6d. each, the value of the steel, originally less than 2d., is raised to £400 and £1600 respectively!

DURING last year 2,887 ounces of gold were procured from 2,336 tons of quartz, which were mined from the slate rocks of Merionethshire.

It has been found that half a grain of lithium given to a guinea pig for three consecutive days could be detected in every texture of the body.

converting vessel. This pipe the patentee now proposes to make of about twice the area of the pipes hitherto employed, in order that it may afford room for the heated spheres *g*, which are supported on rails *f*₁, fixed in the pipes as shown best in Figs. 2 and 3. Each end of the pipe *f* is closed with a lid, and the lower end, or that near the converting vessel, is provided with a stop block to prevent the spheres injuring the lid *f*₃. This end of the pipe *f* is connected to the trunnion of the converting vessel by the syphon pipe *a*. During the melting of the metal for conversion, the spheres are being heated by the waste heat from the melting furnace, or in a suitable oven provided for the purpose, and just before the metal is run into the converter the spheres are run from the oven upon suitable ways to the end

at the bottom is the opening *h*₂; *h*₃ is the pipe for admitting the blast to the vessel *h*, and *h*₁ is the pipe in communication with the trunnion of the converter. The spheres similar to those shown in the pipe *f* having been heated, are allowed to drop into the vessel *h*, the lining of the lower portion of which is protected by a metal plate or by pieces of broken fire-brick, or tap cinder, or other suitable material. The blast becomes heated in passing through the spaces between the spheres.

In Figs. 5 and 6 the blast is heated in passing between the metal tubes *i*, which are secured by flanges or otherwise to the top of the vessel *h*. The tubes *i* are heated by the heaters *j*, which are lowered into the tubes previous to or during the time that the blast is being admitted to the vessel *h*.

The top and bottom of the vessel are held together by vertical stays to resist the internal pressure of the blast, or the tubes may serve as stays by connecting the lower ends to the bottom of the vessel. In this case the heat is conducted through the metal of the tubes, and the heating surface is therefore less effective than when the heat is applied direct as before described. To compensate for this the surface of the tubes is made proportionately greater. It is preferred to make the cylindrical tubes of cast iron, as the pressure is external, and this metal is comparatively strong to resist compression when heated.

The modes above described of constructing the improved heating apparatus are only given as illustrations of the mode of heating air under considerable pressure, and may be considerably modified, as, for instance, more than one line of spheres may be placed in the pipe above described, or more than one pipe with spheres or other heaters may be used, or the heaters may be cylindrical or of any other form that can be conveniently introduced; or in the apparatus shown in figs 4, 5, and 6, ingots from a previous cast may be used as heaters, either by being placed in the vessel *h*, Fig 4, or in the tubes *i* in Figs 5 and 6.

This invention also consists in forcing into the converter, along with the atmospheric air or other gases, carburetted hydrogen gas, or ordinary illuminating gas, in about the proportion of one part of the carburetted hydrogen gas to thirty parts of atmospheric air, to eliminate sulphur and phosphorus from the converted metal; the object being also to render available certain descriptions of iron which, owing to the presence of these elements, cannot now be treated by the Bessemer process.

GAUGES FOR WIRE AND SHEET METAL.

(Concluded from page 64.)

The column to which Section 2 is prefixed in the table inserted in last week's number is called the "metal" or "plate gauge," in contradistinction to the wire gauge. Its intervals are closer and smaller than that for wire. Thus the No. 1, which in this series is the smallest size notch, is 4-100ths or 1-25th of an inch wide, whilst the largest or 36 notch measures 167-1000ths, or is evidently meant for the sixth part of an inch. When thicker metals are wanted, then measures are sought in the Birmingham wire gauge—thus the 36 on the gauge-plate nearly agrees with the 8 on the wire gauge; and so the Nos. 7, 6, 5, to 0000 of the latter are then employed for thicker metals than can be measured by the plate gauge. Frequently the plate gauge ends at 24, which number agrees with 14 of the wire gauge, and then the Nos. 13, 12, 11, to 000 of the latter are similarly resorted to for thicker metals. It is evident these combinations lead to confusion.

Sheet metals also present much variation in their description; for instance, zinc has a gauge thus constituted:

Sheet zinc.....6, 7, 8, 10, 11, 12, 13, 14, 15, 16 (are all nearly alike.)
B Plate gauge.....4, 4½, 5, 7, 8, 9, 10, 11, 12, 13 (all like.)

These thin sheets of zinc, measuring from one to four hundredths of an inch in thickness, are principally used for gutters, roofs, and small works, by the hammer. Thicker zinc plates, from five to eighteen hundredths thick, or those used for zincography, door-plates, and engraved works, are commonly made from notches 18 to 7 of the Birmingham wire gauge, without alteration of the numbers, but running the reverse way of those of the other series used for zinc.

The fourth, fifth, and sixth columns of the table constitute one series of gauges, employed exclusively for the bright steel wire prepared in Lancashire, and the steel pinion wire for clock and watchmakers. The smallest notch in this series is No. 80, and measures 13-1000ths of an inch, or about 1-12th of an inch; and the first part of this series continues with No. 1, which measures nearly one quarter of an inch (227-1000ths). The steel wire gauge apparently ended at this size in the first instance, but has since been extended by a second series to the diameter of 494-1000ths, doubtless intended for half an inch. To avoid confusion, the larger sizes are distinguished by letters, from A to Z, and these terms are then continued under the denominations A1, B1, &c., which latter size is the largest, and measures 494-1000ths of an inch, as shown. There are many other arbitrary gauges—among them those used by rod-iron makers, nail-rod, button, and watch-work makers, also for gun and rifle bores, which need not be particularized. Suffice it that great confusion exists, and that it is high time this arbitrary, incongruous system was removed, and the decimal divisions of the inch employed, and those under

their true appellations. Thus for most purposes the division of the inch into 100 parts would be sufficiently minute, and the measures, 1, 2, 5, 10, 15, or 100 hundredths, would be also sufficiently impressive to the mind; then quantities might be written down, as 1, 2, 5, 10, 15, or 100 hundredths, as the decimal mode of expression might, if preferred, be safely abandoned, and the method would be amply distinct if the gauge were marked "hundredths"—quantities which easily admit of verification.

SWEDENBORG.—No. III.

(Continued from page 63.)

I THINK before my reader has finished the perusal of this chapter he will be more interested in the subject of these papers than he has, probably, yet been. It may be added, *en parenthese*, that the "Principia"—the work we are considering—is rendered very interesting to numbers at the present time, as containing the germs of the system of geological science which now occupies so much and deserved attention, in connection more especially with the duration of our supply of coal.

A remarkable proposition is contained in the chapter on the means which conduce to true philosophy and on the true philosopher—that no one can acquire the former, and not become the latter; also that no one can become a true philosopher who is not a good man. It has been contended by those who do not know anything about the work, that there is an air of mysticism about it which paralyzes attention. That is, I suppose, the attention of supposititious individuals. A late Professor in a University said of it—"It is an extraordinary production of one of the most extraordinary men that ever lived. . . . Many of the experiments and observations on magnetism presented in this work are believed to be of much more modern date, and are unjustly ascribed to much more recent authors." The pervading idea is the recognition of external objects as the product of internal powers, and this, not as to form only, but as to their matter and subsistence. Two things are virtually assumed in all its deductions—the absolute reality of the Infinite and the existence of finite entities; "it has a good foundation therefore in common sense, and has necessarily a religious tendency." Descending from the "first natural point"—by which pure motion is indicated—the author defines the phenomena of heat, light, magnetism, and the elementary substances themselves, as so many graduated manifestations of infinite activity. Many recent "discoveries" are anticipated, such as the identity of electricity and lightning, and the stellar constitution of the Milky Way, and there is promulgated a complete theory of tellurian magnetism. In June, 1752, Franklin performed his celebrated experiment; in 1733 the same truth is reasoned out by Swedenborg as a minor consequent to his philosophy. Respecting tellurian magnetism our author's theory proves the existence of the magnetic element; establishing that, the particles of this element being spherical, the tendency of their motion is either spiral, or vortical, or circular—the importance of this in the connection will presently be seen;—that as each of these motions requires a centre, whenever the particles meet a body which is adapted to their motion, by configuration and position of parts, they avail themselves of it, and form around it a magnetic vortex; and that if this body possesses an active sphere of its own, and its parts are flexible, and if its motions are similar to that of the particles, it will be so much the more disposed to admit them:—thus, that the magnetism of bodies depends on their form. Some of the results of this theory were confirmed in a brilliant manner by our own Faraday; and it is probably destined to take its place, along with Swedenborg's general doctrine of spheres, or exhalations, as the only hypothesis capable of explaining the phenomena and correlation of forces. Respecting the phenomena of planetary motion, various hypotheses had been constructed, on the general principle that the planets were carried round the sun by its supposed vortex. Kepler, Descartes, and Leibnitz had been thrown into the shade by Newton before the publication of the "Principia," but undismayed its author attempted to reconcile the laws of gravity with the existence of a vortex, and, though it still remains for a yet higher authority to pass judgment on this attempt it is sufficient evidence of Swedenborg's genius that the circumstances affecting the periodicity of the comets of Encke and Biela have left astronomers no alternative but an accommodation of this nature. He makes the magnetic element the agency which controls the planetary movements—resolves the power of gravitation into magnetism, and shows that precisely the same laws which govern a single particle of matter govern also the heavenly bodies in their orbital revolutions. Hear him:—"The magnet with the play of its forces

we both see and we do not see. . . . In the magnet and its sphere there is, however, a type and effigy of the heaven; a mundane system in miniature presented to our senses and brought within the limits of our comprehension. In the sphere of the magnet are spiral gyrations or vortices; in like manner in the sidereal heavens there are spiral gyrations and vortices. In every vortex round the magnet there is an active centre; in every vortex in the heaven there is also an active centre. In every vortex round the magnet the motion is quicker near the centre than it is at a distance from it; the same is the case in every vortex in the heaven. In every vortex round the magnet the spiral gyration is of greater curvature in proportion to its nearness to the centre; the same is the case with every vortex in the heaven. In every vortex round the magnet there are, in all probability, corporeal fluids round the centre and revolving round an axis; such also is the case with every vortex in the heaven. The vortices round the magnet colligate themselves by means of their spiral motions, and, thus colligated form a large sphere; the same is the case in the sidereal heaven. . . . All things are similar one to the other; because in small things as well as in large, nature preserves the greatest similarity to herself; especially as the vortices round the magnet possess particles and elements of the same nature as the vortices of the great heaven; and inasmuch as these vortices are similar, as well as their causes, therefore the effects are similar? Our author further remarks that the axis of our own universe is in the galaxy; that here consequently the magnetic power is the strongest, and hence that here we find the greatest condensation of solar systems; that our own sun is not in this axis but a little out of it, and hence the original cause of the ellipticity of the planetary orbits, which he supposes to be attracted in the direction of the axis of the common sphere. It should not be lost sight of all through that it is a stand-point of our author that the visible world is the out-birth of the invisible, and that the manifestations of changes in the external are but manifestations of progression in the state of the internal—hence, according to this, no one can ever well understand the outer without having a knowledge of the inner. Admitting the first part of the proposition, all the rest follows as matter of course.

Respecting Swedenborg's cosmogonical theory it may be remarked that Buffon was acquainted with it, and, most probably, La Place also. The "Principia" was published ten years before Buffon's theory, and about twenty before that by La Place. According to our author the sun is the centre of a vortex; that it rotates upon its axis: that the solar matter concentrated itself into a belt, at the ecliptic; that by attenuation of the ring it became disrupted; that upon the disruption part of the matter collected into globes, and part subsided into the sun, forming solar spots; that the globes of solar matter were projected into space; that consequently they described a spiral orbit; that in proportion as the igneous matter thus projected receded from the sun, it gradually experienced refrigeration and condensation; that hence followed the formation of the elements of ether, air, aqueous vapour, &c., until the planets finally reached their present orbit: that during this period the earth experienced a succession of geological changes which originated all the varieties in the mineral kingdom, and laid as it were the basis of the vegetable and afterwards of the animal kingdom. Swedenborg begins at the centre, La Place at the circumference. Experiments are favourable to the former, and unfavourable to the latter. Again, Swedenborg alleged that there were seven planets created from the sun at the same time: over forty years afterwards Herschel, in gauging the heavens, confirmed the philosopher!

Again, concerning the stability of the solar system our author's theory declares that, as the solar system is carried along the milky path, and afterwards compelled to diverge therefrom, the planetary orbits will change their form and eccentricity to a certain amount, and then return to their original condition, when they will again change, and again return, and so on to eternity. La Grange's demonstration, forty-four years afterwards, is a direct proof of our author's theorem; and yet the doctrine of a cyclic return in the form of the solar system—now received as the most reassuring and beautiful conception of man—is known under the name of La Grange's Theory!

I may return to this part of the work in the next chapter—which may, perchance, be the last, owing to the heavy demands of business, but I cannot leave this without remarking that few who earnestly peruse his works can doubt the transcendancy of our author's genius, or object to his claims for the highest anticipative originality.

(To be continued.)

BIRTH AND GROWTH OF THE IRON TRADE.*

By JAMES ROBERTSON.

(Continued from page 68.)

Cort's invention of the rollers was most important—in this respect, that before his discovery the smallest size of the bars drawn under the hammer was three quarters square; all below that size were made in the splitting mill, and came under the denomination of slit rods. Before that time—that is, the use of the splitting mill in this country—all the slit rods were imported from Sweden. The effect was most disastrous to the nail makers of Stourbridge, but the secret of the splitting mill was transferred to this country in a most singular manner, by the pertinacity of a very humble individual. This man was the founder of the Foley family; he was a fiddler by profession, and lived at Stourbridge when not on his travels, and although he was by no means remarkable amongst his fellows for penetration, yet he saw the great loss of time and labour which nail makers of Stourbridge experienced in cutting the iron for their nails out of flat pieces of iron, and he resolved to find out the secret. He fiddled his way to Hull, and thence worked his passage across the North Sea to Sweden; arrived there, we may justly presume he had a language to learn, as the Swedish tongue is not spoken with correct emphasis in Stourbridge, however well the tones of Foley's fiddle might be understood in Sweden. He elbowed his way to the iron works, and became a great favourite with the workmen, to whom he played. He was an attentive observer of the process of rod splitting; he had seen the machinery, and, as he thought, had mastered its details. He disappeared from the ironworks, and worked his way back to England, to the regret of the admirers of his musical skill. Arrived at Stourbridge, he communicated the result of his voyage to two gentlemen in the neighbourhood: they had works built for the manufacture of slit rods, but when the necessary machinery had been fixed it was found that it did not answer the sole purpose of its creation—it would not act. Back to Sweden went Foley, with his fiddle, as before, to discover his error. The workmen, his former friends and admirers, were delighted to see him. To his inexpressible joy he was lodged in the splitting mill. He made sketches of the machinery to aid his memory; he impressed every detail upon his mind, and made the best of his way back to England, where the works were soon set going, and rod splitting was carried on with the greatest success. He not only enriched himself, but benefitted his countrymen. There are not many such surprising instances of indomitable perseverance as the one contained in this simple narrative.

Another vast stride in the development of the iron trade was the invention of the hot blast, by Mr. J. B. Neilson, civil engineer, of Glasgow, thirty years ago; previous to this it was thought, but most erroneously, that the colder the air upon entering the furnace the better would be the material produced; but the currents of cold air on entering chilled the material, and produced a pipe on either side of the furnace, the furnace having a double blast. These pipes often extended so as to meet in the middle of the furnace, but the duty of the keeper was to watch this and regulate the blast, so that the pipes might be neither too long nor too short. Mr. Neilson suspected that it was the presence of sulphurous vapour which injured the blast, and he concluded that, by heating the air of the blast before it went into the furnace, the evil would be avoided, as air will not support combustion until heated to a temperature of 1000° Fah., and that until it acquired that temperature it would act prejudicially upon the metal. The first experiments of the hot blast were made at a temperature of 300°, and the advantage immediately appeared, for during the first six months of 1829 the furnaces wrought with the cold blast required 8 tons $1\frac{1}{2}$ cwt. of coal (converted into coke) for the converting of 1 ton of cast iron; whilst during the first six months of 1830 the same quantity of iron, with a blast heated to 300°, required only 5 tons $3\frac{1}{2}$ cwt. of coal (converted into coke), which, after deducting 8 cwt. of coal employed in heating the air, gives a saving of 2 tons 10 cwt. of the coal employed in producing a ton of iron. In the course of the year 1831 the temperature of the blast was doubled, being made 600°, and the saving in fuel was enormous, for only 2 tons 13 cwt. of coal (not converted into coke) were required to produce 1 ton of iron, for the increase of combustion with the blast at 600° precludes the necessity of coking before smelting, as the intensity of the blast compensates for the quantity of latent heat that must arise with the vapours expelled from the coals during combustion.

(To be continued.)

NICKEL AND COBALT, AND THE GERMAN SILVER MANUFACTURE.

In an article published some years since in the *Mining Journal* the history of Wollfram from the time it was regarded as an evil by the miner until it attained an enviable position was carefully traced; and in a highly interesting paper, of which the subjoined is an abstract, prepared by Mr. Stephen Baker, of Birmingham, and intended to have been read at the recent meeting of the British Association for the Advancement of Science, the history of the manufacture of Nickel and Cobalt is recorded in an equally instructive manner.

There are few metals, says Mr. Barker, whose history is more instructive than nickel. Originally to the miner a source of trouble and annoyance, it has by a happy combination of scientific observation and manufacturing enterprise in our countrymen—one may, indeed, say our fellow-townsmen—become developed into an important branch of manufacturing industry; and is under its various forms not only an article of luxury, but one of daily necessity to thousands. About the middle of the last century, previous to which nickel was unknown in Europe (though alloys were long previously known in China), the copper miners of Sweden and Germany came upon certain ores of a different character from any they had hitherto observed. They had something of the brilliancy of silver, with the reddish tinge of copper, or rather of bismuth. At Schneeberg, in Saxony, where from time immemorial rich silver mines had existed, fresh lodes of ore were laid open, so glittering and so full of promise as to cause much excitement, and great was the wrath and bitter the disappointment of the honest German miner when, after endless labour and innumerable trials, instead of the virgin white precious metal, ductile, malleable, indestructible by fire, all that he could get from the ores was a dirty whitish metal, brittle and friable, even to dust, under the hammer, and converted by fire into a greyish ash. Whenever the reddish-white ore turned up the miner knew that his labour was in vain, until at length, in sheer vexation, he nicknamed the new villainous ore "Nickel," and another and similar ore generally associated with it "Cobalt"—both these names being at that time applied by the superstitious German miner to certain gnomes, or evil spirits, who were supposed to have bewitched the ore, the mountain, and the mines.

Kronstadt's and Bergman's researches directed the attention of chemists generally to the new metal; and Thernand Lampadius and Buechius contributed to its history. Richter, of Berlin, first produced it in a state of chemical purity in the years 1804, but only in small quantities. The method he adopted was by heating the oxide of the metal (probably with the accidental access of carbonic oxide) in porcelain retorts. It was at first classed among the precious metals. Its great resistance to fusion for a long time formed an insuperable bar to its use in the arts, until a method of alloying it with zinc was discovered; it then became easy to alloy it with other metals, and finally the alloy of the three metals—copper, zinc, and nickel—was known in common under the names of new silver, nickel silver, and German silver.

In the year 1827 a paper, by Dr. S. Erdmann, of Leipzig, "On Nickel, and obtaining it," attracted much attention, and soon after Dr. E. A. Gertner, a chemical manufacturer at Schneeberg, succeeded in producing an alloy of copper, zinc, and nickel, of excellent colour and quality, to which he gave the name of "Argentan." Although after Kronstadt's discovery attention was generally directed to utilise the new metal, and various alloys introduced, under the names of white copper, semi-argent, new silver, &c., the extent of manufacture was quite insignificant previous to about the year 1830. About that time the refining of nickel was first introduced into England by Mr. P. N. Johnson, of Hatton Garden; and soon after Mr. Hallett, of Broadwall, London, commenced the refining of Nickel. At this time the price of nickel was 4s. 6d. per pound. The nickel of commerce was up to this date very intractable for all the purposes of manufacture, except for casting. Spoons, forks, &c. were until this date mostly cast in sand. About the year 1832 a great improvement took place in the refining of nickel. Mr. Askin, at that time following or studying the profession of a veterinary surgeon in Birmingham, had occasion to visit several parts of Germany on business, and having a good knowledge of chemistry, he became acquainted with certain facts relative to the refining of nickel, which led him to devote special attention to the subject; and on returning to Birmingham he succeeded in refining nickel by a purely chemical process—he dissolved the metals, left the nickel in solution by precipitating the impurities, and then threw down the nickel as

oxide. For a short time he was in partnership with Messrs. Merry, to carry out his discovery, but the partnership was subsequently dissolved, and Mr. Askin associated himself with Mr. Brook Evans, under the firm of Evans and Askin. The German silver trade rapidly extended in the year 1840, or thereabouts. The process of electro-plating and gilding first began to develop as a successful manufacture chiefly under the auspices of Messrs. E. Kingston. This gave a powerful impulse to German silver manufacture, which, from its great beauty and durability, soon superseded the old plated copper; and it had the great advantage that whereas copper must always be stamped or spun at a lathe, German silver can be either cast or wrought into a finished design of any article before plating.

Nickel and cobalt, originally found at only a few mines in Sweden, Norway, and Germany, are now found in almost every mining district both of the Old and New World. It may be observed that although the ores of Norway and Sweden are not very rich, they by their abundant supply contribute very largely to our nickel manufacture. One of the most promising nickel mines is at Canton Valais, in Switzerland, but it is now nearly closed. As a rule the mines are not worked for nickel alone, but as an adjunct in mining for other minerals. The price of the metal has varied considerably. In 1840 it was 4s. per pound; in 1849 it had risen to 12s. per pound (?); but it has since gradually come down, until its present price is again 4s. 6d. Commercial nickel, although sold in ingots like the malleable metals, will not roll. The difficulty of obtaining it quite malleable, which it is when chemically pure, has, perhaps, been a cause of its being only hitherto employed as an alloy (German silver), which is composed, according to the requirements of the manufacture, of various proportions of nickel, copper, and zinc. Intimately associated with the refining of nickel is that of cobalt, as they are very generally found together in their ores. Cobalt has been used in the impure state as zaffre, for imprinting the intense blue of porcelain and the better kind of pottery, from time immemorial. About the year 1840 Mr. Benson, of Birmingham, succeeded in refining cobalt by a purely chemical process; however, he had scarcely brought his discovery to perfection at the time of his decease. It was afterwards completed and carried out by Mr. Askin; and Messrs. Evans and Askin continue up to the present time the chief makers of the oxide, that being the state in which it was now used. In 1844 the price was 40s. per pound, but it has been gradually reduced until now it is only about 12s. The number of persons employed in the nickel and German silver manufacture is—in Birmingham, 7,000; and in Sheffield, 5,000; this includes, of course, the manufacture of the various articles in which German silver is used. This production of refined nickel at this time is about 200 tons per annum, equal to about 1,200 tons of German silver.

PHOTOGRAPHY.

DIRECT CARBON PROCESS.—We have received, from Matthew Firling, of Dorchester, whose interesting experiments in carbon printing we have before noticed, two examples of direct carbon printing, with very excellent half tone, gradation, and vigour, one of them being an especially fine print. Regarding them he says:—"I have for the last twelve months past been trying to find some plan by which the carbon process might be worked without re-mounting before developing or transferring to bring the print in its proper position, and I am glad to say that, after trial upon trial, I have succeeded in obtaining a perfect direct carbon printing process, and which is so simple that it can be worked with astonishing ease, and, I think, cannot help being made a commercial thing of in course of time. It is based on the use of a bichromate collodion. I have sent you two prints, but they are not quite so good as I should wish them, but I will try and send some better shortly."

PHOTOGRAPHY AND BOOK ILLUSTRATION.—We understand that Mr. A. W. Bennett is about to add to his series of "Photographic Gift-books" an edition of Scott's "Marmion," and a work by Mr. F. G. Stephens entitled "Flemish Relics, Architectural, Legendary, and Pictorial;" also two smaller works on the "Ruined Abbeys and Castles of Yorkshire," and "The Border."

LUNAR PHOTOGRAPHS.—We have received from Mr. A. Brothers, of Manchester, an exceedingly fine series of photographs illustrating the various phases of the recent eclipse of the moon, and further details regarding them, which will appear in our next.

CHEMISTRY.

MANUFACTURE OF ARSENIC ACID.—Girardin suspends powdered arsenious acid in water, and passes chlorine into the mixture, by which he soon obtains a clear solution of arsenic acid in hydrochloric acid. By evaporating this solution a mass of arsenic acid containing no trace of arsenious is procured. As it is difficult to keep any considerable amount of arsenious acid in suspension in water, the author finds it better to make a saturated solution of that acid in hydrochloric, and pass the chlorine into such solution while hot. The stream of chlorine is stopped when a little of the fluid neutralised with potash no longer gives a green precipitate with bichromate of potash, thus showing that all the arsenious acid has been converted. The hydrochloric acid may then be recovered by distillation, and the syrupy solution of arsenic acid left in the retort evaporated.

ALKALINE METALS AND PYROXYLINE.—Some curious reactions of the alkaline metals upon gun-cotton have recently been discovered, which may possibly throw some light on the decomposition in collodion which takes place when the salts of these metals are present: the facts have been pointed out by Mr. W. S. Scott. In some of his recent experiments he accidentally dropped a piece of potassium upon some gun-cotton lying upon his laboratory table, and was surprised to see that the gun-cotton immediately exploded. He then instituted a series of researches to determine what conditions were necessary for the explosion to take place—whether the phenomenon was the result of moisture; whether other metals would act similarly, &c. He found that, notwithstanding all his precautions to prevent friction, the gun-cotton still exploded. When sodium was employed a like result followed, though the gun-cotton had been rendered perfectly anhydrous. When an amalgam of sodium and potassium was used, no apparent result was produced. Various other metals were experimented with, but decided effects were obtained only with the metals of the alkalis. One of Mr. Scott's discoveries is the fact that when metallic arsenic is mixed with gun-cotton, a blow of the hammer is sufficient to ignite it.

ADVENTURINE.—The composition of Venetian aventurine or aventurine, a vitrified substance containing specks of gold, so much used for brooches and other ornaments, remained for a long time a secret, but two chemists, MM. Fremy and Clemandot, discovered a method of producing it. Their method was to fuse together and keep heated for twelve hours a mixture of three hundred parts of pounded glass, forty parts of protoxide of copper, and eighty parts of oxide of iron, and then to allow the mass to cool very gradually, and in this manner they obtained fine specimens of this artificial precious stone. F. Pelouze, another French chemist, has just communicated another method to the Academy of Sciences; he takes 250 parts of fine sand, 100 parts of carbonate of soda, 50 of carbonate of lime, and 40 parts of bichromate of potash. The glass or enamel thus obtained contains from six to seven per cent. of oxide of chromium, of which about half is combined with the glass, while the rest remains free in the form of those brilliant metallic specks which give the peculiar character to the composition. The Parisian lapidaries who have operated on this new material, give a very favourable account of it as likely to furnish an important material to the jeweller's trade; it is said to be equal to the finest old Venetian aventurine, the metallic lustre of the enclosed specks being very brilliant, and the composition so hard that it will readily scratch and cut glass, and, consequently, is susceptible of a very high polish.

REVIEW.

Tables of Tangential Angles and Multiples, for setting out Curves from 5 to 200 radius. By ALEXANDER BRAZELBY, M.I.C.E. London: Lockwood.

This is something new in the portable line—suited for carrying in a strongly made waistcoat pocket, nicely got up and printed, but liable to get into confusion. This, however, is compensated for by the fact that the hands are set at liberty in using the theodolite, as the card can easily be placed thereon. The tangential tables, and their differences from 360°, are given for chords of the same denomination as the radius; then, when the unit of radius is a chain, the chords also are a chain in length, and so for other denominations. Curves of less than 15 chains radius should be set out in half chain chords, for which the tangential angle for chain chords of double the radius must be used; but the chords of these small radii are given for cases in which great expedition, and only approximate accuracy are required. On the whole, we are inclined to think that the pocket tables will become favourites in surveying, if they are not so already.

GENERAL NOTES.

IMPORTANT MINERAL DISCOVERY IN YORKSHIRE.—A thorough investigation of the district between the village of Lofthouse and the Wernside Mountains, has just been made, the result being the discovery of encaustic grey, black, and other marbles, which had been found in layers to the extent of upwards of 30 feet in thickness, and covering an area of about 10 square miles. They are within 2 feet of the surface, and so abundant and exposed are they that the rocky channel of the River Stean is entirely composed of marble. The river is choked with huge blocks of the material, and its precipitous marble sides, which are polished by the rushing winter floods, are filled with encaustic and other fossils, which peer out in countless myriads along the solid marble faces of the cliffs which hedge in the river. The district is also rich in ordinary limestone, beautiful freestone, lead ore, ironstone, and coal.

DISCOVERY OF OIL IN THE CLEVELAND HILLS.—In the Cleveland iron district large iron royalties have recently, we understand, been leased by several enterprising capitalists, including Mr. George Elliott (of Houghton), Sir Charles Fox, Mr. Murray (contractor for the Portsmouth fortifications), Mr. H. K. Spark, &c., who purpose erecting blast-furnaces upon the ironstone, as from calculations made by Mr. J. G. Beekton, engineer, Whitby, it is ascertained that pig-iron can be produced at 3s. per ton cheaper in this manner than by covering ironstone to meet coke and coal. A most important discovery has lately been patented by Mr. Beekton, which will render the Cleveland district still more celebrated. He proposes to extract oil (similar to the American petroleum) from the shales found above the ironstone. Some of these shales will yield 25 gallons of oil per ton, and the oil can be produced at a cost not exceeding 6d. per gallon. Works are now erecting at Grosport to work this valuable patent in connection with the blast furnace of Messrs. Bagnall.—*Newcastle Daily Chronicle*.

The hundred-thousandth part of a grain of gold may be seen with the naked eye.

In sandy soils, the greatest force of a pile engine will not drive a pile deeper than 15ft.

The relation of the light of the sun to Sirius is as eleven or twelve million to one.

At the gold mines near Halifax, N. S., 1,200 ounces of gold per month are taken out.

It has been stated that potatoes placed in steam boilers will prevent incrustation.

PATENT LIST.

(From the Commissioners of Patents' Journal.)

LIST OF SPECIFICATIONS, &c. PUBLISHED DURING THE WEEK ENDING 28th OCTOBER, 1865.

- 3116. Furnaces for melting iron, &c., J. Ellis—1s.
- 3117. Preparing the surface of parchment, S. W. Hooper—4d.
- 3118. Decorticating or separating cotton seed, R. A. Brooman—8d.
- 3119. Panoramic apparatus, F. A. Chevalier—1s.
- 3120. Cylinders for manufacturing pottery, G. Brown—4d.
- 3121. Closets and commodes, J. White—1s. 10d.
- 3122. Washing and drying wood, &c., W. McNaught—1s.
- 3123. Looped fabrics, W. Cotton—6s. 2d.
- 3124. Portable bedstead, A. H. Robinson—4d.
- 3125. Driving straps or bands, M. J. Haines—10d.
- 3126. Looms, J. L. Norton, and W. Alsworth—2s.
- 3127. Pneumatic apparatus, J. G. Fougere—8d.
- 3128. Railway rolling stock, &c., P. Salmon—4d.
- 3129. Manufacture of hats, F. Cook—5d.
- 3130. Self-acting mules, B. De'vion, W. Slater, and R. Halliwell—1s. 6d.
- 3131. Heating and evaporating, A. A. L. P. Coolidge—1s.
- 3132. Fire-arms, A. H. Benton—4d.
- 3133. Steam blowers, W. Brackes—8d.
- 3134. Liquid meter, R. A. Brooman—1s. 6d.
- 3135. Mills, F. Price—4d.
- 3136. Elastic fabrics, H. L. Hall—8d.
- 3137. Street rails or trams, Z. Eastman—10d.
- 3138. Lamps for railway and other carriages, &c., W. Howes, and W. Burley—4d.
- 3139. Steam engines, H. Davey—4d.
- 3140. Obtaining motive power, &c., W. A. Turner and T. T. Coughlin—4d.
- 3141. Flouges, &c., J. A. Hopkins and G. Culpin—4d.
- 3142. Armour for ships and batteries, W. Tate—1s. 2d.
- 3143. Atmospheric machines, E. C. M. Bonner—8d.
- 3144. Reel-loading fire-arms, E. Swinarski—4d.
- 3145. Water meters, C. W. Orford—8d.
- 3146. Taps or cocks, Sir J. Gais—10d.
- 3147. Composition for casting ships, H. E. McKillop—4d.
- 3148. Furnaces, R. A. Brooman—4d.
- 3149. Elevating shot or shell, Sir F. Blackwood—4d.
- 3150. Reel and stowing jib sails, J. Butchart, H. Stroud, and S. A. Morrison—10d.
- 3151. Making lines, braids, cordings, and edgings, E. T. Hughes—1s. 2d.
- 3152. Slide valves, &c., H. J. H. King, H. K. Smith, and J. B. Howell—1s.
- 3153. Apparatus for removing heavy bodies, D. Miller—4d.
- 3154. Box for velvets, braids, ribbons, &c., W. J. George—4d.
- 3155. Pump, H. Draneau, and F. Laidet—6d.
- 3156. Signalling to railway trains, S. F. Lettice—4d.
- 3157. Textile fabrics, H. Cannon, and T. Bosman—4d.
- 3158. Fastenings for books, &c., G. Leach—10d.
- 3159. Fire-arms, T. A. Grinist—8d.
- 3160. Treating sewage matters, H. Bird—4d.
- 3161. Manure, S. P. A. De Brocade d'Eluz—4d.
- 3162. Plier bend for booms, W. Mayne—4d.
- 3163. Spinning, J. P. Y. Livingston—10d.
- 3164. Varnish for metals, H. A. De Bion—4d.
- 3165. Reel-loading fire-arms, T. Woodward—1s.
- 3166. Iron bridges, J. Westwood—3d.
- 3167. Hair-brushing apparatus, C. E. Bryant, and S. Middleton—8d.
- 3168. Machine for sheet and cap fronts, rouches, &c., C. G. Hill—3d.
- 3169. Governors, M. Henry—2s. 4d.

- 3170. Aggregating coal-dust, F. Tolhausen—4d.
- 3171. Hydraulic and other engines for obtaining motive power, &c., J. Kamsbottom and T. Blackburn—1s.
- 3172. Signalling in railway trains, &c., J. W. C. Brewer and W. Warren—4d.
- 3173. Working hydraulic presses, cranes, &c., L. R. Bodmer—4d.
- 3174. Cattle wagons, W. Reid—1s. 2d.
- 3175. Photographic apparatus, J. H. Johnson—8d.
- 3176. Looms, J. Hargreaves—8d.
- 3177. Call and other bells, E. Wilson—10d.
- 3178. Lamp feeders, H. Edmonds—6d.
- 3179. Propelling vessels, J. P. Thor, III, and J. H. Fothergill—10d.
- 3180. Lighting pipes, J. G. Aram—8d.
- 3181. Pressing cotton, &c., C. G. Wilson—1s. 6d.
- 3182. Governors, J. Byrne—1s.
- 3183. Currency, J. K. Leath—4d.
- 3184. Making aerated bread, H. F. Howard and J. Daughlish—1s. 6d.

A TREATISE ON GASWORKS, and the Practice of Manufacturing and Distributing Coal Gas. By SAMUEL HUGHES, C.E. Second edition, illustrated, revised by WILLIAM RICHARDS, C.E., price 2s. VILFRED BROTHERS and Co., Amen Corner, London.

SCREW CUTTER'S GUIDE,

Price 1s. 6d., or stamps. Containing 115 Pages and nearly 2,000 Prints of Wheels, all different threads and pitches. Tables for Tap-making for Engineers, & 4 to 6 inches, Gas Taps 1/2 in. to 2 inches, Mr. Whitworth's thread and taps. A lithograph showing a new radius gear invented by the author of this work. May be had at James Martin, 19, Wilson-street, New Cross-road, Deptford, Kent.

NEW WORKS PUBLISHED

BY
E. & F. N. SPON,
16, BUCKLESLURY.

Just published, 8vo. cloth, price 18s.

PRACTICAL SPECIFICATIONS of WORKS
executed in ARCHITECTURE, CIVIL and MECHANICAL
ENGINEERING, and in ROAD-MAKING and SEWERING: to which
are added a Series of practically useful Agreements and Reports.
By JOHN BLENKARN, Civil Engineer and Architect.
London: E. and F. N. Spon, 16, Bucklersbury.

Royal 82mo. roan, price 5s.

A HANDBOOK FOR ARCHITECTURAL
SURVEYORS, and Others Engaged in Building.
By JOHN THOMAS HURST, C.E.

CONTENTS.

Formulae useful in Designing Builders' Work.
Tables of the Weights of Materials used in Building.
Memoranda connected with Builders' Work.
Architectural Mensuration.
Constants of Labour.
Valuation of Property.
Summary of the Practice in Dilapidations.
Scale of Professional Charges, for Architects and Surveyors, with
various useful Tables and Memoranda.

London: E. and F. N. Spon, 16, Bucklersbury.

Just published, elephant folio, cloth, price £2 3s.

Also in Limp Binding at the same price (can be rolled up in a
small compass without injury to the plates).

PRACTICAL ILLUSTRATIONS of LAND
and MACHINE ENGINES, showing in Detail the Modern
Improvements in High and Low Pressure, Surface Condensation,
Superheating, together with Land and Marine Boilers.

By N. P. BURGESS, Engineer.

London: E. and F. N. Spon, 16, Bucklersbury.

Royal 82mo. roan, 4s. 6d., post free,
RULES for DESIGNING, CONSTRUCTING,
and ERECTING LAND and MARINE ENGINES and
BOILERS.

By N. P. BURGESS, Engineer.

London: E. and F. N. Spon, 16, Bucklersbury.

Eighth Edition, in royal 82mo. roan, price 4s. 6d. post free,

A POCKET BOOK of USEFUL FORMULÆ
and MEMORANDA, for Civil and Mechanical Engineers. By
GUILDFORD L. MOLESWORTH, Memb. Inst. C.E.

London: E. and F. N. Spon, 16, Bucklersbury.

Just published, on a Sheet, price 1s.

DELANY and OKE'S TABLES for
ENGINEERS, SHIP BUILDERS, CONTRACTORS, BUILDERS,
&c., from a quarter of an hour, in regular progression, to nine hours
and three-quarters, and from one day to ten days, at 1s. to 5s. per
day.

London: E. and F. N. Spon, 16, Bucklersbury.

Just published, royal 8vo., price 7s. 6d.

THE SEWING MACHINE: Its History,
Construction, and Application. Translated from the German
of Dr. HERZBERG, by UPFIELD GREEN, Illustrated by Seven
large folding Plates.

London: E. and F. N. Spon, 16, Bucklersbury.

600 pages, crown 8vo., price 10s. 6d.

PERPETUAL MOTION. Its History during
Three Centuries, with ample Descriptions and Illustrations.
By HENRY DIRCKS, Civil Engineer.

London: E. and F. N. Spon, 16, Bucklersbury.

Royal 8vo., cloth, illustrated with 41 Plates, price 18s.

A PRACTICAL TREATISE on the SCIENCE
of LAND and ENGINEERING SURVEYING, LEVELLING,
ESTIMATING QUANTITIES, &c., with a General Description of the
several Instruments required for Surveying, Levelling, Plotting, &c.
By M. & M. KILGATT.

London: E. and F. N. Spon, 16, Bucklersbury.
Just Published, royal 4to., half-bound, illustrated by 84 Plates of
Furnaces and Machinery, price 22s.

THE IRON MANUFACTURE of GREAT
BRITAIN, Theoretically and Practically Considered; including
Descriptive Details of the Iron, Piles, and Piles employed; the
Preliminary Operation of Calcination; the Blast, Refining, and
Puddling Furnaces, Engines and Machinery, and the various Pro-
cesses in Union, &c. By WILLIAM TURKIN, C.E., formerly En-
gineer at the Dowlais Iron Works, under the late Sir John Guest,
Bart., subsequently at the Barrow and Furness Works, under Mr.
Crawshaw. Third Edition revised from the Manuscript of the late Mr.
Turkin. By J. Arthur Phillips, Author of "A Manual of Metallurgy,"
"Records of Mining," &c., and W. H. Dorman, C.E.

London: E. and F. N. Spon, 16, Bucklersbury.

Just Published, post 8vo. cloth, 2s. 6d.

MEMOIRS of the DISTINGUISHED MEN of
SCIENCE OF GREAT BRITAIN, LIVING A.D. 1867-8. By W.
WALKER, Jun., with an Introduction by Robert Hunt, F.R.S.
Second Edition, revised and enlarged.

Containing the lives of Watt, Binnie, Telford, Mylne, Jessop,
Chapman, Murdoch, the first to introduce gas into practical use;
Barnard, Huddart, Boulton, Brunel, Watson, Benthams, Mandley,
Dalton, Cavendish, Sir Humphry Davy, Wollaston, Hatchett, Henry,
Allen, Howard, Smith, the father of English geology; Crompton,
inventor of the Spinning Mule; Cartwright, Tennant, Ronalds, the
first to successfully pass an electric telegraph message through a long
distance; Charles Baird, Stanhope, Trevithick, Nasmyth, Miller of
Delawation, and Hymington, the inventors and constructors of the
first practical Steamboat; Professor Thomson, of Glasgow; Troughton,
Donkin, Congreve, Herschel, Maskelyne, Baily, Frahmham,
Lea, Playfair, Rutherford, Dollond, Brown, the Botanist; Gilbert
and Banks, the Presidents of the Royal Society at that epoch of
time; Capt. Kater, celebrated for his pendulum experiments; Dr.
Thomas Young, and Jenner, the benefactor of mankind; Jas. Ivory,
Dr. Priestly and Cort, the father of the iron trade.

London: E. and F. N. Spon, 16, Bucklersbury.

HOLLOWAY'S OINTMENT AND PILLS.—

EXPERIENCE BEFORE AUTHORITY.—For nearly the
third of a century have these remedies stood in the foremost rank
for overcoming ulcers, sores, swellings, rashes, and all descriptions of
skin diseases. At first the faculty denounced these medicaments, but
the experience of sufferers soon overthrew all interested opposition.
Those whom Holloway's medicines had cured told other invalids the
benefit they had derived from their use; those in their turn tried them,
found equally satisfactory results, and thus are these admirable cura-
tives used and prized throughout the habitable globe. The Ointment
has always been applied with the most marked success in erysipelas,
varicose veins, swollen ankles, and numerous other infirmities by
which thousands around us are sorely oppressed.

"EXCELSIOR," "EXCELSIOR"

Family Sewing & Embroidering Machine

WITH ALL THE LATEST IMPROVEMENTS.

IS easy to operate, simple to learn, quiet in action, and not liable to derangement. It will TUCK, HEM, FELL, GATHER, CORD, QUILT, BRAID, and sews from two ordinary reels, requires no re-winding, and the seam, if cut at every inch, will not rip. Price from £6 6s.

WHIGHT AND MANN, 143, HOLBORN BARS, LONDON.

MANUFACTORY—GIPPING WORKS, IPSWICH.

PRICE LISTS FREE.

Crickmer's Patent Plastic Metallic Packing.

FURTHER REDUCTION IN PRICE ON AND AFTER OCTOBER FIRST.
PATENT WIRE GAUZE JOINT PACKING... 1s. 6d. per lb. INDIA-RUBBER CORE PACKING (HEMP)... 1s. 4d. per lb.
CRICKMER'S PATENT PACKING... 2s. 3d. Do. (JOINT)... 2s. 6d. Do. (JOINT)... 2s. 6d. Do. (JOINT)... 2s. 6d.
This Packing takes less Tallow to lubricate it than any other, and being a Pliable Metallic Surface requiring but little Pressure to keep it Steam tight, there is a great saving in friction.
PATENT TALLOW PUMPS AND LUBRICATORS.
WELL STRETCHED LEATHER MILL BANDS, HOSE PIPES, FIRE BUCKETS, VALVES, WASHERS, &c., &c.
CAUTION.—Engineers, Millowners, and others are cautioned against Purchasing a Spurious Metallic Packing, purporting to be Crickmer's. THE GENUINE CAN ONLY BE OBTAINED FROM
ALEX. ROSS AND CO.,
GRANGE ROAD, BERMONDSEY, or their Authorized Agents. Price Lists upon application.

The most reliable tool of this kind, graduated to the Standard Measure of the Realm, and manufactured with MARVELLOUS ACCURACY, may be obtained of

RICHARD LLOYD,
MILL AND MACHINE IRONMONGER
135, STEELHOUSE LANE, BIRMINGHAM.

Clubs of Workmen supplied at reduced prices. No equal tool is sold under FOUR TIMES THE PRICE.

CHANGE WHEELS FOR SCREW-CUTTING LATHES.

NOTICE TO INVENTORS.—Office for Patents, 4, Trafalgar-square, Charing-cross. Printed instructions (gratis) as to the Cost of PATENTS, for Great Britain or foreign countries. Advice and assistance in disposing of or working inventions. Branch offices and agencies in every Continental State and in America. Established 30 years. Full information as to expired or existing Patents at home or abroad. Apply personally or by letter to Messrs. PRINCE and Co., Patent Office, 4, TRAFALGAR-SQUARE, CHARING-CROSS, W.C.

TO CONTRACTORS, ENGINEERS, SHIP BUILDERS, COLLIERY OWNERS, &c.—Sections and Prices forwarded on application for Boiler, Bridge, Boat, and Ship Plates, Angle, Tee, Beam, Girder, and Dock Iron of all sizes; Sheet Iron, Plain, Corrugated, or Galvanised; Wire Rods for drawing, telegraph, or fencing; Black or Galvanised. Wire Ropes; Permanent, Colliery, or Tram Rails; Hoop Iron, Bar Iron, Nail Rods, Split Nut Iron, Gutter, Bevelled, Taper, Convex, Half Round, Sash, Tyre, and all descriptions of Fancy Iron; Bar Iron of all sizes; Wrought Iron Forgings, Castings, and Railway Material of every description.

JOHN HORSLEY,
Iron Agency Office,
2, ST. ANN'S SQUARE, MANCHESTER.

PLANS, ELEVATIONS, &c., Made, Copied, Traced, Reduced, or Enlarged, in the best manner, at moderate charges, by J. J. GREENE, 63, Upper Stamford-street, Blackfriars.

THE LENOIR GAS ENGINE.—A number of these useful and economical engines to be seen in actual work in town and country. Being free from all danger, they can be used where steam power is totally inadmissible. Exhibition, and every information supplied at 49, Cranbourn-street, Leicester-square, W.C.

THE LONDON DRAWING ASSOCIATION for supplying Engineering, Mechanical, Architectural, and General Drawing, Designs, Maps, Plans, Tracings, Wood Engraving, Electrotyping, 7, Duke-street, Adelphi, London. Enclose stamp for prospectus.

JOHN SHEPPARD, of 10, Marsden-square, Manchester, has specially adapted himself for the supply of ENGINE-CLEANING WASTE, at the following prices: White at £22 per ton; grey, £25 per ton; coloured, £31 per ton. Wadding Material, for wadding manufacturers, at equally low prices, in bleached, crimson, grey, and black. Liberal terms to shippers.

TO INVENTORS.—GENERAL PATENT OFFICES.—L. de FONTAINEMOREAU, 4, South-street, Finsbury, London; 10, Rue de la Fidélité, Paris; 32, Rue des Minimes, Brussels. Provisional protection, £7; to complete patent, £30; French patent, £6 10s.; Belgium, £2 10s. Circula gratis on application.

TUCK'S PATENT STEAM PACKING.

TUCK'S PATENT ELASTIC PACKING AND METALLIC LININGS FOR STEAM-ENGINES, PUMPS, &c.

ADVANTAGES.—A more perfect vacuum is obtained. Friction reduced, great saving in oil and tallow, and the Packing is gradually and completely worn away without becoming hard, thus obviating the necessity of drawing the Old Packing.

PATENT HOLLOW STEAM PACKING.

THE great and peculiar advantages of this packing consist in its remaining perfectly elastic, and is so constructed and applied that the pressure of the steam itself makes the joint by entering the packing from the cylinder; thus the many objections to packing previously existing are effectually removed.

Valveless India-rubber Sheet Washers, Valves, Springs, Hose, Glazed and Solid Tubing for Gas, Speaking Tubes, Diving Dresses, Gas Bags, Air-proof Goods, or any description of India-rubber articles made to order.

Prices list or circular, with full description of packing, to be had of the only Manufacturers and Patentees of Hollow Steam Packing.

"THE ARTIZAN."

PATENT OFFICE & DESIGNS REGISTRY,

(Office of "The Artizan" for Scotland).

W. R. M. THOMPSON & Co., 20, Buchanan-street, Glasgow, Consulting Engineers and Patent Agents, in connection with

WILLIAM SMITH, Esq., C.E., Director of the Artizan Patent Office, London, Proprietor and Editor of the "Artizan," a Monthly Record of Engineering and the Industrial Arts, TRANSACT ALL BUSINESS RELATING TO BRITISH AND FOREIGN PATENTS FOR INVENTIONS, AND THE REGISTRATION OF DESIGNS, AND EXECUTE PLANS AND SPECIFICATIONS OF ALL KINDS OF MACHINERY IN THE MOST CORRECT MANNER, AT THE LOWEST POSSIBLE CHARGE. Provisional Protection, 25s. Ordinary Charges for Complete Patent, £42.

All general information in reference to Patents given free on personal application, or by letter, when an addressed stamped envelope is enclosed.

The "Artizan" supplied, and all business for it in Scotland may transacted at the above Office, 20, Buchanan-street, Glasgow.

LLEWELLINS & JAMES,

BRASSFOUNDERS,

COPPERSMITHS, AND ENGINEERS,

BRISTOL

Sole Makers of Clements'

ECONOMIC LUBRICATOR,

FOR MARINE, LOCO, AND FIXED STEAM-ENGINES.

(As supplied to the Admiralty, and many Engineering and Steamship Companies.)

This Lubricator offers a perfect method of lubricating all the internal parts of the steam-engine, by the vaporisation of the lubricant, saving, at least, half of the oil or tallow generally used, and lessening the "wear and tear" consequent upon imperfect lubrication.

PRICES, COMPLETE, WITH GUN-METAL FITTINGS:—

2 Pints, 62s. 6d.; 3 Pints, 67s. 6d.; 4 Pints 75s.

BRIGHT GUN-METAL BODIES, EXTRA.

As they are fixed on the steam-pipe, the diameter of this should be given; and it should also be stated whether horizontal or vertical.

BRITISH AND FOREIGN PATENTS AND THE REGISTRATION OF DESIGNS.

Mr. H. H. MURDOCH having succeeded to the Business of his late Father, which has been established upwards of Thirty Years, offers his professional services to Inventors. A circular, containing full information respecting the various modes of securing protection for invent one at home and abroad, may be had, Gratis, by applying personally or by letter, at his OFFICE FOR PATENTS, 7, STAPLE INN, LONDON.

E. BOURDON'S PATENT GAUGES.—GIFFARD'S INJECTORS.

Drawings and Prices on Application to

W. T. HENDRY, & Co., 73, QUEEN STREET, LONDON, E.C.

PATENTS.

MR. VAUGHAN, Member of the Society of Arts, British, Foreign, and Colonial

Patent Agent, 54, Chancery-lane, W.C.

Transacts every description of business connected with Letters Patent for Inventions. Provisional protection, 6s 8 guineas. A "Guide to Inventors" free by post.

SAMUEL BROTHERS,

Suits for all Occasions

36s. to 114s.

OVERCOATS,
21s., 28s., 33s., 42s., 55s., 63s.
BOYS' OVER COATS, 12s. 6d. to 35s.
Boys' Suits 16s. to 35s.
50, LUDGATE HILL.
The new Book with 42 Engravings (36 being Portraits), illustrating the most fashionable attire, will be sent post free for six stamps, which sum is deducted from a purchase.

FIG. 3.

COMBINED OVAL AND ECCENTRIC CHUCK.

In kindly forwarding the drawing of the excellently contrived chuck, illustrated on the front page—which is probably as good an arrangement as is now extant—its author, Mr. Wm. Muir, of the Britannia Works, Manchester, says:—"Pressure of business has alone prevented me attending sooner to your request. This chuck is shown fixed on a 6in.-centre lathe headstock, part of which is shown in section, fig. 4. The several figures are marked with corresponding letters of reference. Fig. 1 is the front elevation, fig. 2 is the back view, fig. 3 is the plan or end view, and fig. 4 is the section through the centre *f, g*. A is the front plate of chuck carrying the tangent wheel, B the back plate screwed on the nose of the mandril, C is the oval ring fixed to the lathe headstock, *e e* the pallets fixed on the steel slides on the back of the front plate A. When it is required to use the chuck as an eccentric one remove the oval ring, and if to use as an oval chuck remove the screw D by taking out the small screws *i i*. Those acquainted with the ordinary chuck will observe that any piece of work can be operated upon by either the oval or eccentric movements. We understand that this arrangement was a favourite with the late Mr. Holtzapffel, and remains still in as great favour. We are sure our readers are much obliged to Mr. Muir for his kindness, and for ourselves we shall be glad to hear as "effectually" from him again. What the cost of this arrangement is we do not know, but not less than £10 we fancy would purchase it new.

ANSWERS TO CORRESPONDENTS

ENGRAVER.—The amount of premium will vary from £20 to £150, according to the standing of the employer. A good workman will earn from 3s. to £3 per week.
HARG.—Received; your ideas are exceedingly good, but there are already many in the same field.
T. F. R.—Write to Mr. Bennett Woodcroft, office of the Commissioners of Patents, Southampton-buildings, Chancery-lane.
JOHN W. HUMPHREYS.—Perhaps in a future number.
THOS. BUTTERWORTH.—The omission was unavoidable; you will see the list is again inserted as usual.
H. BOYCE.—Consult a gunsmith. We cannot possibly judge without seeing the gun. Your publisher ought to procure the title-page and index for you; he can obtain them in any number from his wholesale agent.
JAMES BYRNE.—Received.
GEO. STANLAND.—Search back, the question has been often answered.
AGATE.—They are published in the *Social Science Review*, Whitefriars-street. We have received numerous applications for the memoir.
G. J. P.—We cannot undertake to engrave the requisite diagrams.
J. FAYOR.—See the article on Telescopes in last number.
PARADOX.—Will be attended to.
LIONEL BUCK.—We have no space to answer so many questions as you put to us.
W. E. BRAMWELL.—Thanks for your kind letter; some of the arguments you urge are perhaps correct ones, but you must bear in mind that according to our sub-title we are bound to give space to other subjects than practical engineering.
INGONYMA.—Search through the back numbers, the question has been repeatedly answered.
DAUNT.—Your first question has been very recently answered in this journal; for the work you want try Spon, publisher, Bucklersbury.
MAURICE CLIFFORD.—The price will depend upon the size and quality. A small advertisement in any of the scientific papers will bring you lots of offers from which to take your choice.
AN AMATEUR.—We cannot spare the space for the illustrations, but you will find them in some of the cheap works published by S. O. Beeton.
HENRY MORTON.—All that you require would occupy many of our pages and need many engravings; why not obtain the works written on the subject from Spon, Weale, and other booksellers. See advertisement pages.
EDWARD LEE.—We are of opinion that most of the valuable suggestions in your letter will shortly be carried out.
CHARLES MORTON.—Received.
T. S. MERRIT.—Fret saw, next week.
VELOCIPEDE.—James Hearn, of North-street, Manchester-square, is willing to assist any one in making a velocipede having just succeeded in perfecting one to his satisfaction.
WM. TAYLOR.—We know of no such society.
J. S.—Write again.
JAMES W. IMESON.—Write to Messrs. Holtzapffel, 127, Long-acre.
MAGNETISM.—Explain yourself more clearly.
Z. Y. X.—Search back, you will find the process fully described in a recent number.
COUNTRY BUILDER.—We know of no other way than consulting the advertisement pages of the trade journals, and acting with caution.
C. B.—Thanks; attended to.

* * We have to ask our correspondents to sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them

by the thousand; the same with "Well Wisher," &c. If they don't like to see their own names paraded, use those of an ancient or any other man.

Several letters remain over till next week for answer.

Letters applying for information to be furnished by post cannot be attended to.

Correspondents are requested to keep copies of their drawings and manuscripts, as the Editor cannot undertake to return such as may be rejected.

NOTICE TO ADVERTISERS.

Advertisers in this journal are respectfully informed that the Collector from the office, 162, Fleet-street, will call upon them for a settlement of the amounts due for the insertion of advertisements. The Collector will in every instance hand in a printed receipt for the sum paid to him. Advertisers are particularly cautioned against paying money without receiving the printed receipt.

An Advertisement Canvasser named BURLER has no authority from the Proprietor of the "English Mechanic" to collect money from Advertisers or others.

THE ENGLISH MECHANIC!

Just Ready, and now Publishing, the

FIRST VOLUME

OF
THE ENGLISH MECHANIC.
A Record of Mechanical Invention, Scientific, and Industrial Progress.

UPWARDS OF ONE HUNDRED
ILLUSTRATIONS.

Handsomely bound, only 4s. 6d.; post free, 5s.

GEORGE MADDICK, 162, FLEET-STREET, LONDON,
and all Booksellers.

THE ENGLISH MECHANIC.

Every Tuesday, One Penny. Monthly Parts, 5d.
Now Publishing, complete, the First Volume.
* * Title Page and Index, One Penny. Cases for binding, One Shilling and Sixpence.
It is solicited that all back Numbers be ordered at once.

All the early Numbers have been reprinted. It is therefore necessary that sets be made up at once, as there will be no further reprints owing to the great expense they entail.

162, FLEET-STREET, LONDON, and all Booksellers.

TO ADVERTISERS AND CORRESPONDENTS.

* * In future all Advertisements and Communications for the Editor to be sent to
162, FLEET-STREET.

OUR MONTHLY PARTS.

Part 7 of THE ENGLISH MECHANIC, in coloured wrapper, is now ready.

Price 5d. only! Post free, 7d.

All back Nos. have been reprinted, and can be had direct from our Office, or through any bookseller.

TO ADVERTISERS.

As the ENGLISH MECHANIC addresses itself to the largest and most intelligent portion of the community, and is the only Paper of the kind established, it offers unusual advantages as an advertising medium.

SCALE FOR ADVERTISEMENTS:

	£	s.	d.

Every additional Line (Nine Words) ...	0	3	0
Whole Page	...	...	...
Half Page	...	...	...
One column	...	...	...

Post-Office Orders to be made payable to GEORGE MADDICK, Fleet Street Branch.

All Advertisements should be sent to us not later than Friday.

The English Mechanic.

FRIDAY, NOVEMBER 17TH, 1865.

WAGES AND PRICES IN NORTH AMERICA.

IT is a difficult matter to get at the true state of the case, as regards the working man in the States—the details vouchsafed being extremely few, and the dates of their delivery far between; but we have been favoured with a list from Cincinnati, which seems to be a carefully prepared comparison of wages and prices in that city in 1860, and at the present time. From personal acquaintance we can speak to the truth of much of it. Now, as Cincinnati

is a large city, making excellent progress, it probably admits of being looked upon as giving the average of the country. As a rule, the advance of wages in private employ has been 100 per cent., but much less in public and company service. Machinists, who earned from £1 16s. to £2 8s. in 1860, now earn from £3 4s. to £4. The rate for locksmiths has advanced from £1 16s. in 1860, to £3, and £3 12s.; whilst painters who got £1 16s. in 1860, now get on an average £4 4s. Tailors used to make coats at £1 6s. to £1 8s., now they get £2 16s. They made vests and trousers at 7s., and now get 13s. 6d. Cigar makers, in 1860, got from 18s. to £1 4s. per 1,000; now they have £2 16s. Bricklayers, who got 8s. to 10s. per day, previous to hostilities, now get 18s. to £1. Carpenters, who got 7s. to 8s., now get 12s. to 16s. The wages of plasterers have advanced from 5s. or 6s. to 12s.; and of hod-carriers, from 4s. or 5s. to 12s. Gunsmiths now earn £3 12s. to £4 per week, though in 1860 the best of them only received £1 16s. to £2 8s. Bookbinders have also risen in value; women who got 14s. to 16s. per week in 1860, now get £1 8s. to £1 12s. Men's wages, which were from £1 16s. to £2 8s., have risen as high as £3 to £4. The wages of boot-makers have risen fully 75 to 100 per cent. The wages of blacksmiths, boiler-makers, and street-pavers, have advanced 100 per cent. Clerks and teachers have only advanced from 25 to 50 per cent.

Turning to prices—rents in Cincinnati have doubled. Groceries, provisions, and liquors, have advanced more than other articles of necessity—in some items to thrice the price they were in 1860! If these prices are inflated their fall must bring down wages: so that things may be said to be on the average, much as they were.

THE BISCUIT MANUFACTURE.

TO the general reader it may have appeared that hand-labour only is utilised in the manufacture of the Biscuits, of every-day life. But when it is considered how many thousands and tons of these products are every year consumed, and at how low a rate of remuneration, it is evident that machinery alone can accomplish the task. It would be invidious on our part to mention any particular firm as especially engaged in this department of industrial commerce; but it may be taken for granted that mechanical contrivances are here largely introduced, on every hand. All the appurtenances of extensive trade, in such establishments, are visible externally and internally, and the realities do not fall short of a worthy and honourable comparison. There are cranes and wind-lasse, labour-saving contrivances in abundance, hoists, lifts, bake-houses, &c. The flour is deposited by steam, sifted by steam, and the sugar is mixed and pulverised by the same indefatigable agent.

The mixers are in a high loft, and are of cylindrical shape, standing on strong and unshaking supports of solid iron. In the centre of the cylinder, running through from side to side, is a rod of iron, armed with huge knives, and as the revolutions occur, these knives chop and cut, and incorporate the dough thoroughly. They appear something dreadful in their revolutionary garb of sharp antagonism. From the floor above, to the centres of these mixers, the dough with water is conveyed; and so the mixing is made complete, effectual, and interminable. When in proper condition, this dough is conveyed similarly to the floor below, where are the bakehouses. The mixing pans are of metal, revolving on pivots, and a moveable roller connected therewith completes the triturating and incorporating processes.

The Cutting and Stamping Apparatus.—This machine receives the dough, in the form of a finely-laid sheet, on to a metal table, which table is made to move slowly underneath a roller, that levels the dough-sheet to the requisite thickness. The sheets of dough are then passed over a cylinder and stamped, the sliding plane or frame taking them into and through the oven at a sufficiently slow rate to allow of proper baking on their passage. Here the part of the frame on which the last row of biscuits lay is hinged, and thus they are allowed to tip up and drop off into shallow drawers with grated bottoms, for the purposes of cooling. The stamping of the huge dough sheets must be done very evenly, or on one side of the sheet there will be cut out imperfectly sized biscuits, and on the other side a long fringe of dough will remain to be anew worked up. The temperature of the oven must also be looked to, or economy of speed will be sacrificed—for the moving plane on which the stamped sheets are placed being always on the journey through the oven from front to back, too little heat there will necessitate a slower journey, and too much the baking and burning of the product.

The cracknel-making apparatus is a round boiler, full of hot water, into which the stamped dough cakes are thrown, whence they are removed to the baking pans, thence to the ovens, coming out subsequently in their characteristic form.

We are favourable to the introduction of machinery in these hand-making processes, on account of the cleanliness thereby secured, and the accuracy therein demanded. The human hands, in the biscuit manufacture, have very little to do except to attend to the machinery. The dough is made, mixed, spread out, stamped, passed through in the oven, in shape, nicely browned and baked, delivered at the back of the apparatus in fit eatable condition, with a speed and accuracy most surprising. The quality is also as superior as the appearance.

THE SILVERED GLASS PROCESS.

WE are not about to divulge trade secrets, but merely to narrate what may be interesting to the uninitiated, and to the general reader.

The apparatus necessary in the silvering-glass process are, first, a beautifully level slab of iron, or steel, placed over a huge oven, heated by gas or in other suitable way, and supplied with all the means for gradual cooling. Now, suppose, we need to silver over a flat surface of plate glass; we shall cleanse it well with filtered water and a chemical solution, and then place it on the heated iron slab, before referred to.

A solution of nitrate of silver (in colour as pure water), in combination with a reducing agent, of which the character and composition are secrets, is now poured carefully and evenly over the surface of each sheet of glass—as a photographer disposes of his developing and sensitizing solutions, while the attendants watch the effect of the heated slabs. Soon the nitrate of silver, acted on by the reducing chemicals through the medium of heat, begins to deposit itself slowly and evenly on the surface of the glass sheets; and when these are covered with a coppery hue (this being the then appearance as they lie on the iron slab), they are poised up on one end, rubbed down gently with a kind of rag brush, note being taken of all defects in the deposition of the silver—for there are sure to be some after the laying on of only one solution—and then lifted off the slab to be dried. These handlings require much care; for the sheets, although of great thickness, frequently fly in all directions from no apparent cause, and considerable loss of profit is the result. When dried, the plates are treated to a repetition of the silvering and other processes, and are then worthy the critical examination of the most fastidious. The undimmed splendour of the glass is perfect; its silvery hue not to be approached by any other reflecting medium.

But glass is a little more difficult and expensive in its mode of operation, as moulds have to be made to suit the needed curve. The glass-sheet must be well and evenly supported in every part, or it is liable to fly in a moment, and great expense is often caused by such contingencies. So, in the curved products, the solution is more difficult in the laying on, and the expense is greater, but the effect is exquisite. The silvered-glass is backed up by a kind of red paint, that will not wash off or wear away, and its production is a great secret in the trade. To resist damp and wet in the "backing-up" is a *sine qua non* in this manufacture.

This glass-silvering, as is apparent, may be largely and most advantageously used for decorative purposes. In these days of competitive industry, it is no slight advantage to have a mode of adornment elegant and not too expensive; and our "building" friends may perhaps devise way for the use of silvered glass at present unknown to fame. Already it darts light upon our darkness, multiplies our illuminative power, seemingly extends the confined area of modern shop-erectures; and may perhaps in the future be as largely used for exterior elaboration. It is a process that may not even yet be perfect.

REVIEW.

The Slide Valve Practically Considered. By N. P. BURGH, Engineer. London: Spon, Bucklersbury.

This is a book which, from the examination we have bestowed on it, we consider it would be well were it in the possession of those who have to design and fit engines; for of all the details of an engine that of the slide valve is the most important. Its defective action impedes the progress of the whole; hence the necessity to producers, of having a handy reliable work at hand such as this is. The book, says Mr. Burgh, is intended to enable the student and interested observer, to clearly understand the use and action of the detail in question.

The rules relating to the equilibrium slide valves, have, he states, been carefully digested, and judging from what we have seen, the statement is perfectly correct. The following recommendations we willingly endorse:—"The delineation of the eccentric circle should be well studied, it being remembered that from it the slide is proportioned. The angles assumed by the cranks at given grades of expansion are too often disregarded by the pupil and young engineer. It is not usually appreciated that the arc passed through, determines the lap of the valve. In no case whatever should a valve be designed without first considering the direction of the crank pin, and the amount of expansion required. The proportion of lap to width of opening or port can only be obtained by the means alluded to. The lead of the slide valve has been duly considered. The author would impress that the true versed sine and radius of the arc of supply steam can only be obtained, by *noticing the lead*." The time for supply, expansion, exhaustion, and compression has been fully explained, so that its value and defects will be apparent. The delineation of the crank axle has met with due attention, and will be found of utility in proving the actual consumption of the steam at each stroke of the piston. Furthermore, it may be stated that Mr. Burgh has carefully avoided theorizing on his subject; all his remarks have been deduced from practical demonstrations—assumptions have not been admitted—therefore the data will be found exact. There is a handy excellent index appended, which will be found of great assistance by the reader and student. The illustrations are boldly executed, and quite sufficient for their purpose. By the way, there is a chapter—not by any means the least in importance—of "General Observations," which will be found very suggestive and handy by many. We regret much that we have not room to spare for a more extended review, illustrated from the examples given by Mr. Burgh.

SWEDENBORG.—No. IV.

(Concluded from page 79.)

CONCERNING the translatory motion of the stars along the Milky Way, no conjecture had been formed anterior to the publication of Swedenborg's theory.

In his statement, our author says:—"The common axis of the sphere or sidereal heaven seems to be the galaxy where we perceive the largest congeries of stars. . . . The solar or stellar systems afterwards proceed from the axis, and inflect themselves in different directions; but that, nevertheless, all have reference to that axis. . . . The largest congeries in the Milky Way . . . here lies the chain and magnetic course of the whole of our sidereal heaven." This part of my subject may fitly be closed with the following extracts from the "Principia," which have been amply "facted" by the joint labours of the two Herschels and Lord Rosse:—"That one vortex, with its vortive centre, constitute . . . one mundane system; that several vortices, with their centres, form together a certain sphere; that a sphere, consisting of many vortices of the same kind, has its own proper figure. . . . That the whole visible sidereal heaven is one large sphere, and that its suns or stars, together with their vortices, are parts of a sphere connected one with the other, in the manner we have mentioned. . . . That there may be innumerable spheres or sidereal heavens in the finite universe; that the whole visible sidereal heaven is, perhaps, but a point in respect to the universe. The sidereal heaven, stupendous as it is, forms, perhaps, but a single sphere, of which one solar vortex constitutes only a part. Perhaps there may be innumerable other spheres, and innumerable other heavens similar to those we behold: so many, indeed, and so mighty, that our own may be respectively only a point." To me, there is something very grand in these few last lines.

Some eleven or twelve years since, the work by Reichenbach, entitled "Physico-Physiological Researches on the Dynamics of Magnetism, Electricity, &c.," created quite a sensation. In that work we are presented with many engravings, showing the actual flame which goes forth from the ends of magnets, and from all sides of them, also from the human hand, body, &c. Reichenbach discovered these flames by partially clairvoyant subjects, when shut up in a dark room. The flames proceeding from the poles of a large horse-shoe magnet, capable of supporting 50 lbs., were described as about eight inches in length, mingling with iridescent colours, flickering and waving, yielding when blown upon, &c. Various experiments with other bodies are also here detailed, and the force which enveloped these flames is called the "odilic" force. To say the least, it is interesting to observe in Swedenborg's "Principia"

precisely similar drawings, illustrating the same sphere around magnets and around iron. Reichenbach demonstrated the existence of these spheres as magnetic flame and light, by means of his patients or subjects. Swedenborg has similar drawings, illustrating precisely the same thing, all but the flame; and as the spheres include the flame, though not seen, the coincidence is interesting. Space there is not for any of the drawings, but a few of our author's remarks may be quoted. "By reason," he says, "of the connection between the vortices which extend from one pole to another, and of the formation of the sphere, there exist poles, one on each side of the magnet: there exist, in like manner, polar axes extending in the sphere to a distance from the magnet; and these axes do not receive their determination from the magnet, but from the sphere and its figure. That not the magnet, but the sphere, forms the polar axis on each side, is evident from this circumstance—that the polar plane passes through the magnet from one side to the other, as in [figure] where the whole [of one] side is polar, as is also the opposite side, and the elements of the effluvia travel within the mass rectilinearly . . . according to the interior texture. Hence the polar axis cannot have any fixed place in the magnet, but the place and situation of the poles are owing entirely to the sphere, which is compelled to encircle the magnet according to the figure of the latter. . . . By the application of two or more magnetic spheres, the figure of each is immediately changed: from two or more arises one that is larger; and the whole of the distance between the spheres becomes an axis." (A comparison here with Reichenbach is curiously interesting.) "The sphere of the effluvia around now extends itself to a considerable distance, so that the vortices or gyrations of effluvia emit themselves like radii on every side, and dispose the magnetic element itself into the same situation, whence the magnetic element regards the iron as its pole or centre from which the vortices issue in a long series. Not only does a tide of effluvia perpetually emanate from the iron, but it also conatipates and surrounds its surface—a circumstance so evident, and from so many phenomena arising from the conjunction of the magnet with magnetic needles, as to be placed beyond a doubt."

In 1734, in his forty-sixth year, our author published his "Philosophy of the Infinite, or Outlines of a Philosophical Argument on the Infinite, and the Final Cause of Creation; and on the Inter-course between the Soul and the Body." This and the "Principia" gave Swedenborg an European reputation, and his correspondence was eagerly sought after by such learned men as Wolff, Flammstedt, Delahire, Varignon, Lavater, &c., and in December of 1834, the Imperial Academy of Sciences at Petersburg appointed him a corresponding member. At this time he was a diligent student of Wolff's philosophy; and whoever compares the writings of the two, will find an immeasurable superiority in those of our author.

From 1734 to 1736 he remained at home, and during this interval he conceived the project of his great physiological works. In the latter year he obtained leave to travel, to gather matter for their completion, and went through Denmark, Hanover, Holland, visiting Antwerp, Brussels, Rotterdam, &c., and in 1738 arrived in Paris. As a characteristic of our author, the following is valuable, taken from his note-book, wherein it was entered during his sojourn in Paris:—"My walk [in the gardens of the Tuileries] was exceedingly pleasant to-day; I was meditating on the forms of the particles in the atmosphere." Leaving Paris in 1739, he crossed the Alps into Italy—passing through Turin, Venice, Verona, Mantua, Milan, Genoa, Florence, Pisa, and entering Rome in the fall of the year. It is stated that, while at Rome, he published two dissertations on the nervous fibre and the nervous fluid, one on intermittent fever, and several others; and there is no doubt but that previous to these he had finished his "Economy of the Animal Kingdom," published at Amsterdam in 1740-41. This work is in three parts—the first on the blood, blood-vessels, and heart, with an introduction to rational psychology; the second on the animation of the brain synchronous with the respiration of the lungs, on the cortical substance of the brain and the human soul; the third treats principally of the human fibres, and expounds the various manner in which the beams and timbers of the body are laid, especially the construction of the frame—somewhat as the "Principia" unfolds the elementary construction of the universe. It also considers the different kinds of fibres, the form of their fluxion, and the doctrine of forms generally; and lastly, in a masterly manner, the diseases of the fibres. In the weightiness of its truths, in sustained order of exposition, in felicity

of phrase, and in finish and completeness, it is not surpassed by any scientific work that the author published. It is utterly impossible to devote space to an analysis of this great book, but room can be made for an extract from a critique in "The Forceps," a London periodical, well known some twenty years ago:—"This is the most remarkable theory of the human body that has ever fallen into our hands, and by Emmanuel Swedenborg, too!—a man whom we had always been taught to regard as either a fool, a madman, or an impostor, or, perhaps, an undefinable compound of all the three. Wonders, it seems, never will cease, and, therefore, it were better henceforth to look out for them, and accept them whenever they present themselves, and makethem into ordinary things in that way. For thereby we may be saved from making wonderful assees of ourselves and our craft, for enlightened posterity to laugh at. What has the world been doing for the past century, to let this great system slumber on the shelf? . . . It is clear that it yet knows nothing of its greatest men. . . . Swedenborg's doctrine is altogether the widest thing of the kind which medical literature affords, and cast into an artistic shape of consummate beauty. The book is a perfect mine of principles, far exceeding in intellectual wealth, and surpassing in elevation, the finest efforts of Lord Bacon's genius." The praise is every whit deserved.

Then we have treatises following, on the brain, on generation, on the ear and hearing, on the human mind, and on common salt. I would add, just as a fill in, that in 1852, the Royal Academy at Stockholm had its annual medal struck in memory of Swedenborg, the eulogium on whom was delivered by the President, General Akrell.

Here, it appears, must close my review of Swedenborg as a man of Science; into the realm of theology I may not enter, though I doubt not many of my readers will feel disposed to learn what so great a man has to say on what is rightly considered in our day a most important matter. Should any feel so disposed, I, standing at the portal now, may assure them that what lies behind the veil is greater than that laid open in these pages. Respecting his work as a man of science, it is proper to add that he was not so much a collector as he was a systematizer of facts, and a discoverer of their hidden causes. "Many," says he, "stubbornly refuse to stir a single step beyond visible phenomena for the sake of the truth; and others prefer to drown their ideas in the occult at the very outset. To these two classes our demonstration may not be acceptable. For, in regard to the former, it asserts that the truth is to be sought for beyond the range of the eye; and in regard to the latter, that in all the nature of things there is nothing but is either already the subject of demonstration, or capable of becoming so."

From the time at which we have left him, until his death in Great Bath-street, Coldbath-square, London, on the 29th March, 1772, he was almost solely engaged in his theological works, by which, at the present day, he is best known. He occasionally travelled about ere his body found final rest in the Swedish churchyard, Ratcliff-highway. In person Swedenborg was about 5 feet 9 inches high, rather thin, and of a brown complexion. His countenance always bore a cheerful smile, which added a charm to its expressiveness, and his general appearance was dignified and venerable. I will conclude by quoting the words of the Rev. O. Prescott Hiller:—"As he becomes more known, surprise and admiration take the place of neglect and contempt; the earnest searchers for truth wonder that they had not been directed to this light before, and the intellectual and the learned are astonished that they had passed by a thinker and writer who far excels them in intellect and learning."

I may add that my authorities are a "life" by Rich, unfortunately out of print now, one published by O. Clapp, of Boston, U.S., in 1854; Whyte's "life" (Pitman, Paternoster-row), but principally the works themselves, to be had from Mr. Alvey, Bloomsbury-street, for whose kindness, and for the portrait which accompanied No. 1, I have to return my thanks. The works themselves, all things considered, are published at a very low price. Brief and disconnected as this compilation has, almost of necessity, been, I trust it may have done something towards creating an interest in the writings of Emmanuel Swedenborg. E. C.

The produce of the New Almaden mines for the last ten years has averaged about 2,500 flasks of 76½lb. each of mercury per month.

The total value of the minerals obtained during 1864 was £31,603,047, the value of the metals produced being £16,231,869.

LETTERS TO THE EDITOR

[We do not hold ourselves responsible for the opinions of our correspondents.]

MUCH WORK AND LITTLE PAY.

Sir,—In a commercial point of view the electric telegraph is undoubtedly the greatest blessing of the age. I have noticed when the wires of all the companies, owing to some severe gale, have been entirely useless between Liverpool and London, that the confusion and excitement among the commercial population is not easily describable, and indeed it would for a short time entirely cause the suspension of all important business, and great inconvenience to those, whose sales, &c., depend on an early reply by wire?

I will with your permission say a few words on those individuals to whom are intrusted the secrets of the cabinet, the interest of our banking concerns, and the commercial transactions of the country generally. They are expected to be well educated and to maintain a respectable exterior, and for these requirements they receive the magnificent amount of from 16s. to 25s. per week. Now, if your readers would fancy for a moment the style of living of a clerk having a wife, and maybe two or three little ones depending upon him for support would be at the above rate of payment.

The companies pay such excellent dividends that I really think they should at least remember the source of their wealth, and the high prices of provisions at the present time fully justifies the clerks in making a complaint. If you would kindly give this room in your paper it might, at least, tend to bring about the above desired result, and I assure you will have the grateful thanks of about 15,000 telegraph manipulators. AN OLD CLERK.

HINT TO MECHANICS.

Sir,—In your invaluable work appears many articles which must be very useful and of great benefit to the working mechanic, and from which I for one have derived a great deal of information.

There is a trifling thing I wish to bring under the notice of joiners, pattern makers, and all who use a whetstone with oil, that paraffin oil is the best for that purpose; it only requires a trial, but the stone must be free from all greasy oil before it is applied. MAONANISTA.

RAYS OF THE SUN, MAGNET, &c.

Sir,—In answer to F. Mason, the actinic rays of the sun have the effect of withdrawing the oxygen from all bodies through which they pass; consequently, the fire dies only from want of the vital element, oxygen, which is withdrawn by the actinic rays. If, however, a piece of yellow glass is interposed between the fire and the sun, it will absorb the actinic rays, and the fire will again be surrounded by oxygen, and therefore burn well.

In answer to J. B. place two pieces of steel, and connect them by two pieces of soft iron, as shown in the diagram. Then rub them round with a horse-shoe magnet 3 or 4 times, always taking care to end in the same place as commenced at, they will then become magnets.

The poles will be opposite one another, as shown. If the pieces of steel to be magnetised are horse-shoe shaped, they are to be placed opposite one another in this manner, and then proceed, as for straight pieces.

Another way:—A piece of glass tube is to be introduced within a helix of covered copper wire the two ends of the wire are to be connected with the two poles of a battery. The piece of steel to be magnetised is then placed within the tube, and it instantly becomes a magnet.

P.B.—The condenser described by T. Stohard is only available for galvanic battery or coil apparatus.

OUR SUBSCRIBERS' NOTES AND QUERIES.

Sir,—Can any of your scientific readers inform me whether there has ever been invented a lathe that would turn either gun stocks or shoe lasts, or anything of a similar shape—that is, anything not perfectly round? An answer in your valuable paper will be esteemed a favour by NEMO.

Sir,—Can any of your numerous readers inform me how to obtain ivory black in quantities without paying the high price charged by the shops. W. SHORR.

BRONZING.

Sir,—If any of your readers can assist me by publishing through your columns a recipe for copper bronzing, the same as the different kinds of figures are done, you will greatly oblige a constant reader of THE ENGLISH MECHANIC. H. T. B.

LUBRICATING MEDIUM.

Sir,—Can any reader tell me the best lubricant for the leading screw and tin nut of a screw-cutting foot-lathe, the screw-cutting mechanism of which is not often put in use? I have been told to apply black-lead, but am afraid of its thickening the oil with which I presume it should be mixed, and that it might scour or waste the surfaces it is intended to save. IGNORANS.

INDIAN INK.

Sir,—If any of your readers could inform me of the best method of preparing liquid Indian ink, and what to put in it to prevent its forming a deposit on the bottom of the bottle, it would greatly oblige A DRAUGHTSMAN.

MONOSTEREOSCOPES.

Sir,—Will any of your subscribers oblige me with practical information, or suggest where obtainable, viz.—how to construct an efficient "Monostereoscope." F. J. BALL.

SILVERING GLASS.

Sir,—Would you be so kind as, in your answers to correspondents to inform me how, in silvering glass, I can overcome the difficulty of having the tin-foil eaten into holes by the quicksilver before I can get the glass upon it; the quicksilver does not flow, and I have tried to spread it over the foil with my finger, but before I can get a sufficient part of the surface covered the foil splits and dissolves in several places. DOW. QUIXORS.

ENGINEERS' SCREWS.

Sir,—I should feel obliged if some of your subscribers would favour me with the number of threads to the inch (Whitworth's), for engineers' screws, say from ½ in. up to 1 inch. ABBOW.

CHEMICAL.

Sir,—I am a photographer, and of course have quantities of residues in the shape of hypo-sulphates of silver, and nitro-chlorides of gold. Can any of your readers assist me in applying them to silver plating and gilding. HARRO.

Sir,—Can any of your readers inform me the publisher and price of one or more works on Natural Magic? THEO.

STEEL POLISH.

Sir,—Can any of your readers tell me the best way to tin glass brooches, and also how to polish and revive steel car-rings and brooches that are rusty. GEO. SMITH SPOOL.

STICKING LEATHER ON TIN.

Sir,—Many thanks to Thomas Jackson for his answer on gas purifiers; could he tell what composition is used for sticking the leathers on the tin in dry meters, or where I could obtain it? VESTA.

BORING CANNON.

Sir,—Could any of your readers inform me the best mode of boring cannon, how they are adjusted upon the lathe, and what tools are used for them? YOUNG TURNER.

CEMENT.

Sir,—Could you or any of your numerous readers inform me what cement to use to fix the spindle in a plate electrical machine? CHEMISTS.

CONTACT BREAKER.

Sir,—I would feel greatly obliged to Electra, or any other person skilled in the manufacture of coils, if they would answer me the following question: Will silver do instead of platina for pointing the screw and plating the spring of contact breakers? ANSELM SPLAINS.

Sir,—If anyone will tell me how to dissolve the hard surface of cast-iron so that a file will readily cut it, they will much oblige T. H. B.

MAGNETO-ELECTRIC MACHINES.

Sir,—Will any of your readers kindly tell me the difference between a permanent and an electro-magnet, such as are used in making magneto-electric machines; also, how they are made, and the sort of iron that is used in them? J. C. WIGG.

Sir,—Can any of your readers inform me what kind of tool is used to make that checked work we see on gun stocks? M. B.

FLY WHEELS.

Sir,—Could any of your readers inform me of any rule by which I can calculate the weight and diameter of fly-wheels for engines of various sizes? J. D. E.

ELECTROTYPE MOULD.

Sir,—Can any subscriber inform me how to make a flexible mould for electrotyping undercut work? SCIENTIFIC.

PRESSURE IN BOILERS.

Sir,—In answer to T. G. Maugh, requesting to know how to find the pressure of steam a boiler can bear by means of the safety valve—if he means the pressure allowed by the safety valve, the following will be found correct:—

$$\frac{a \times c}{b} = \text{total weight on } d,$$

which, being known, the pressure on the square inch can be found by dividing the total pressure by the area of the valve in square inches. — a = the length between weight and valve spindle; b = do. valve spindle and standard; c = the weight in pounds. G. S.

Sir,—Optical glasses in the raw state can be had of Messrs. Chance Brothers and Co., Birmingham. By sending a stamped envelope to them they will send a tariff. DAVID KNIGHT.

FRICTION GEARING.

Sir,—In answer to C. E. A., Sheffield, No. 30, I send an inclosed sketch of friction gearing, which I think will do for the purpose he requires.

C represents the shaft of the machine to be put in motion, the drum B being fixed upon it, and the drum A, A', running loose; G is a sliding bar, with forks for guiding the belts F, F', which are driven by the drum D giving contrary motions to A, A', by one of the belts F being crossed by moving the bearer F to the point S, the belt E is brought to the position, S driving the shaft (C) in the direction of the arrow A, at the same time the belt (E') is moved to H'', and it is on that account that the drums A'' and A''' are made twice the width of B. By putting the lever back to H'', the motion of C is reversed, and by returning to M'' is stopped.

T. PARKER.

TO CUT CIRCULAR PIECES OF GLASS.

Sir,—If Mr. C. Smart has a turn table on which he mounts his objects, and a writing diamond in his possession, he has, I think, all that is required to cut the circular pieces of glass. It is only necessary to fix the square pieces of glass on the centre of the table, and hold the diamond with the right hand while he turns the table with the left.

The following diagram will illustrate all that is required:—

A, is the stand for table; T, table; P, pole fixed into stand of table; O, arm to hold the diamond; K, K, keys to tighten the arm O, and the diamond D; G, the square piece of glass fixed to table by the two pieces of brass, B, B, which each have two holes, so as to tighten the piece of glass G. The pieces of brass are fixed by two screws, as can be seen. These two pieces of brass will do to hold the slide on the table when required for mounting objects.

DAVID KNIGHT.

Sir,—The whetstone spoken of by R. F. W. is not to be mended by the aid of cement. Let him put it in an oven for about an hour, and pour some green sealing-wax upon it while hot. It will soon be as firm as ever.

O. BATHURST.

HARDENING COFFEE MILLS.

Sir,—If Give and Take, in October 18th, p. 27, will try prussic acid of potash, I've no doubt he will succeed in hardening his coffee mill by making it cherry red hot.

VISTA.

HYDRATE OF ALUMINA.

Sir,—J. E. may precipitate hydrate of alumina from a saturated solution of any kind of alum in water by adding a solution of carbonate of ammonia, or carbonate of soda (common washing soda will do).

IRIDESCENCE.

Sir,—Flinders Owen.—Iridescence is produced by engraving microscopic lines, about 2000 to the inch, on the surface of metals, &c. Messrs. Barton and Co., of Birmingham, I believe have ornamented buttons and other articles in this way by a machine constructed for the purpose. When pearls are viewed through a microscope they exhibit similar lines, which reflect the light at such angles as to

produce the various coloured appearance termed iridescence. Impressions of pearls taken in gutta-percha or other material is said to exhibit a similar appearance.

COLOURING GAS.

Sir,—John Turner, I think, will find it impossible to produce gases of different colours for nearly all permanent gases are colourless; chlorine, however, is an exception being a yellowish green colour.

John Cloyd, No. 28 will probably find what he requires in O'Neill's "Dictionary of Calico Printing and Dyeing." J. H. M.

Sir,—I send tracing of two diagrams showing position of piston at different parts of stroke.

In setting the slide valves of oscillating engines, should the steam cut off at $\frac{1}{2}$ stroke be taken from $\frac{1}{2}$ stroke of piston, or $\frac{1}{2}$ revolution of crank. In reference to diagrams, Fig. A shows the different points of piston divided equally. Fig. B shows position of points in path of crank divided equally. Will any of your readers explain which is right?

D. T. K.

JOINING TORTOISESHELL.

Sir,—In answer to W. H. O., No. 30, Vol. II., he will find that heating the edges of tortoiseshell before the fire, and pressing them together till set, will join them strong enough for all practical purposes.

J. D. E.

PISTON ROD.

Sir,—Delta does not say in No. 28, Vol. II., whether his cylinder is of iron or brass, if the latter make a double grooved piston of same material, and pack it tightly with well-oiled cotton, such as is used for wicks in spirit lamps, &c.

J. D. E.

IMITATION MAHOGANY.

Sir,—X. Y. Z., p. 27, Vol. II., will find the following receipt to answer his purpose:—Boll logwood chips in water, adding a little soda or potash to bring out the colour. Apply with a brush, and use French polish when dry. For rose wood, a stronger decoction of log wood must be used, and the process must be repeated several times. To produce the fibres, put some iron filings or turnings in strong vinegar; let it stand for some years, and then brush the wood over with the solution. When dry, polish with beeswax and turpentine.

J. D. E.

TO PURIFY OIL.

Sir,—H. Feather, p. 40, Vol. II., may purify oil in the following manner, which is quite good enough for common watches and clocks. I have used it with every success:—Fill a phial three parts with olive oil, and hang it up in a window for six months, where it is exposed to every change in the weather. The impurities will then be precipitated.

J. D. E.

DANIEL'S BATTERY.

In answer to Query, under the head of "Daniel's Battery":—

If Alfred Crofts will substitute sulphuric acid (one acid to eight of nine water) for water, which he places between zinc and porous tube, he will find his battery answer well; if not, increase size of copper suspending some bluestone vitriol in sulphate of copper solution.

WM. HOSKIN.

SPLITTING SYCAMORE.

Sir,—I see in THE ENGLISH MECHANIC an enquiry as to how to prevent the splitting of sycamore to be used for rollers in the business. I have spent most of my life till the last four years; we use large quantities of sycamore for rollers and bowels from six inches to twenty or twenty-four inches diameter, and from three to four feet six inches in length. We at once, or as soon as convenient, saw the timber into lengths, and generally bore them through the centre, which appears to be the best preventative from splitting, which to me seems very reasonable. If the centre is left in, there is no space left for the wood to shrink to; but the outside very naturally shrinks as the its juices evaporate from the wood; the middle retaining

moisture, does not shrink, which, resisting the shrinking of the other, causes it to crack. There may be some better method. This is the experience of thirty to forty years.

J. B.

P.S.—Logwood, as a dye for mahogany, I think will not be very good. The least contact with iron will soon turn black.

ADAMANTINES.

Sir,—You can purchase the emery stick or properly called adamantines, in shape of pillar files, or round, for chamerfering or reducing enamel glass or soft gobbles, at Mrs. Hitchins, watch tool dealer, 8, Lion-street, Coventry.

SPIRAL SPRING.

ASSAYING.

Sir,—H. F. will find Mitchell's "Manual of Practical Assaying," about 12s. 6d. answer his purposes.

HARDENING PLASTER.

GUSTAVUS.—Dissolve a small quantity of alum in water before mixing; the plaster will set quicker and harder.

MAGNETISM.

J. B.—From the Electro-Magnet.

ELECTROTYPE.

F. B.—Cauterize with stearine. When quite dry, with blacklead (plumbago).

SOIMATT

SLIDE RULE.

Sir,—In answer to Young Mechanic, in No. 30, there are instructions published for the common slide rule, price 6d. They may be obtained, I believe of almost any bookseller, or he will find a full description of it with its uses.

CINA.

[Next week the first of a series of articles on the engineer's slide rule will appear in THE ENGLISH MECHANIC, written by Mr. W. Tonkes.]

ELECTRICAL MACHINE.

Sir,—I beg to thank Mr. W. Hart for the promptitude and courtesy, with which he answered private enquiries respecting Winter's electrical machine.

W. STRODS.

GENERAL NOTES.

A NEW DECANTER.—A very ingenious contrivance has been made by M. M. Toselli and D'Allmagne of Paris. They blow a small globe within a decanter or claret jug. This globe, which has its opening at the side of the larger vessel, serves to hold a freezing mixture to cool wine or water in summer, and in winter may be filled with warm water to take the chill off Burgundy or port.

We understand that Mr. Culverwell, the secretary to the Great Northern Railway of Ireland, having satisfied himself by a fair trial of the superior efficiency and simplicity of Captain Norton's patented railway detonators, has ordered a large supply for the Northern line. The great advantage in these detonators is, that there are no iron nipples within to rust nor copper caps to create verdigris.

ASTRONOMY.

An astronomer in the United States, in an attempt to account for the colour of variable stars, assumes that a star emitting white light while approaching the earth would, by reason of its velocity, appear to us of a reddish colour. At its perigee it would be white, changing to blue as it moved away, and becoming white again at the apogee. To illustrate his view, he finds an analogy in the whistle of a locomotive. "Here," he says, "as you approach the sound, its impulses reach you more frequently than if its source and you were at rest. At the instant of passing, you receive the normal number of impulses, and after passing the impulses reach you less frequently. The shrill shriek, the real tone, and the low roar in this case are facts which I suppose to be parallel to the red, the white, and the blue light of a star moving swiftly, first towards, and then from us."

PHOTOGRAPHY.

ENLARGEMENTS ON PAINTER'S CANVAS.—Mr. J. E. Palmer, whose photographic enlargements on canvas for oil painting we have before had occasion to speak of in high terms, referring to the method described in M. Truchet's specification published in our last, asks us to state that he does not employ either wax, spermaceti, gum, elemi, or collodion in his method, and adds that he will guarantee them not to crack or peel from the canvas.—*Photographic News.*

COLLODIO-CHLORIDE ON CANVAS.—It will be obvious to any one disposed to try Truchet's process of photographing on canvas, that the use of collodio-chloride of silver, instead of collodion requiring the use of a silver bath, will materially simplify the process, and probably improve the results.

VELOCIPEDE.

In consequence of not being able to get the engravings completed in time, we are compelled to defer the article on velocipedes until next week.

THE MANUFACTURE OF COKE FROM SMALL SLACK.

The existence of immense quantities of fine coal slack in the South Staffordshire and other mining districts, in a state almost, if not quite, commercially valueless is a fact well known to those acquainted with the coal and iron trade of this country. The fact that most of this slack, which has hitherto been considered waste, possesses all the chemical properties of the coals from which it is derived has also been some years forcing itself upon the attention of those interested, and stimulating their efforts to recombine it as a fuel suitable for smelting, and other purposes. The difficulties in the way of coking the Staffordshire slack arises from the fact that although possessing the valuable properties for which Staffordshire coal is noted, it does not possess sufficient bituminous matter to cause it to cake or bind in the process of coking. The most successful method of coking the Staffordshire is found to be by mixing with it a certain portion of bitumen, in the shape of Welsh or other bituminous slack. The greatest difficulty at present experienced is with respect to the ovens, as in those hitherto in use the heat developed in the process of manufacture is not applied with an effect or uniformity sufficient for the thorough fusion of a thick mass of slack, and the production of good hard coke. The charges are found to be caked only in layers at the top and bottom, the interior of the charge being imperfectly fused and waste.

It is with a view of remedying this defect in the process that the ovens patented by Messrs. Hicklin and Pardoe have been designed. The principle upon which they are constructed is that of causing the flame and gases from each oven, in a group, to enter into a common system of flues passing over and under every oven in the series, thereby causing a thorough intermixture of the gases, the development of intense heat, and the application of the same in a more uniform and effective manner than hitherto, the coking chambers being, as it were, enveloped in fire. It is found that the ovens will thoroughly fuse and convert into best hard coke thick charges of Staffordshire slack, with a less proportion of bitumen than is used in any other ovens, and without waste. The charges are so thoroughly fused that they are drawn *en masse*, the doors being as wide as the ovens. Any one or more of the ovens in a series can be drawn and re-charged without interfering with the others, and the charge is immediately ignited by the heat of the contiguous ovens and upper and lower flues, and in its turn contributes to the general effect. The perfect combustion of the gases (as shown by the absence of black smoke from the chimneys) develops an intense heat, which after expending itself upon a long group of ovens, is still sufficiently powerful to be applied to useful purposes, such as raising steam for working engine, and for heating and drying purposes generally.

PRESSURE PISTON PACKING.

A new pressure piston packing machine has been invented by Mr. Andrew Stevens, master mechanic on the Alameda and San Leandro Railroad. Steam is admitted into the body of the piston through small valves, and by its pressure and expansive force keeps the rings steamtight against the cylinder without creating any undue friction. The valve on the steam side remains open until the pressure in the cylinder, either by expansion or exhaust, falls below that in the piston, when it closes, and the steam by its expansive force retains the rings against the cylinder to the end of the stroke, when the action is again repeated. Among the advantages claimed are—1. Absence of friction of the rings on cylinder proved by the tool marks remaining on the cylinder after six months' constant running. 2. The retention of the steam inside the piston by means of the two valves, thereby preventing waste. 3. The steam being of the same pressure inside of the piston as it is outside, the piston may overrun the counter-bore without damage, and thereby prevent a ridge being formed in the ends. 4. The body of the piston fitting the inside rings keeps the piston always in the centre of the cylinder. 5. The increased ring surface, which wears much longer than narrow ones. It is not only the saving in steam and fuel which lends importance to this invention. The economy in the cost of machinery for a given amount of power must be equally great, as also the benefit to be derived from the concentration of power into small space and weight.

DRILLING AND BORING.

DRILLS used in boring works chucked on the lathe have long shafts, some parts of which are rectangular or parallel, so that revolution may be prevented by any suitable means, such as a hook-wrench, or a spanner. The drill shaft ends are pierced with centre holes to allow of being thrust forward by the poppet-head either by hand or self-acting motion. For holes requiring great accuracy the lathe drills 1, 2, 3, are mostly used. Fig. 1 is the half-round or cylinder bit. Its extremity is ground somewhat inclined to the right angle, horizontally and vertically to the extent say of from three to five degrees. To commence, turn out a shallow recess to the diameter of the end of the bit: thus the circular part of the bit will fill the hole and be retained centrally whilst the left angle takes off the shaving. The tool noticed should not be sharpened on its diametrical face, or it would cease to be a half round bit. Generally it is made smaller behind to lessen friction; and the angle not intended to cut is a trifle blunted halfway round the curve to prevent scratching from pressure of cutting edge. The rose bit, fig. 2, has its extremity

fig. 6, and so on in rotation until the hole is finished. We will now notice a few other boring tools, to which time has affixed the stamp of use.

Fig. 7 is a lathe drill invented by Mr. Collas, of Paris. It is turned as a cylinder, and perforated to three or four diameters, with a hole one-tenth its exterior size. One third of the cylindrical end is removed to form a longitudinal incision extending to the centre, having radial sides; the extremity of the drill is ground somewhat as in Fig. 1, to make the one edge cut; behind the angular part a further portion is reduced to the diametrical line; the remainder is either square or cylindrical, and ends in a poppet-head centre. A shallow recess having been turned out to allow the end of the bit to be inserted, the bit bores the hole in the solid metal to the depth required. Mr. C. Holtzapffel's boring bit, with changeable cutters, derived from the half-round bit, was contrived for boring holes, so as to avoid the expense of the long boring bits required in boring models of guns, &c.

The work is made as in Fig. 8, and detached as Fig. 9. The stock end is made cylindrical, with a notch across the extremity extending below the diametrical line, also a longitudinal groove on the under side. The notch receives the cutter *c*, which takes the flat edges of the stock, and is held by two screws; the groove takes the bearing piece *b*, which also is fixed by screws, countersunk. The outer parts of *b* and *c* are turned cylindrical and hardened, the cutting angle *c* being allowed to be always more prominent than the two other parts. Holtzapffel made one stock thus, to serve for various diameters from $\frac{1}{16}$ in. to $\frac{3}{16}$ in., another for sizes between $\frac{1}{4}$ in. to $\frac{1}{2}$ in., so as between them to answer for boring all ordnance models for the Government. For drilling the preparatory holes below $\frac{1}{16}$ in. diameter, the system above noted was used, to ensure exact centres and straightness of bore; and in forming the curved chambers of the models different cutters with tail screws were inserted in a hole tapped on the axis of a long boring bar, also used in the latter. The scheme was eminently successful.

The Cornish (Fig. 10) is a useful lathe drill. The stock is cylindrical throughout (except where squared for the hook-wrench above noted), is enlarged at one end, and has a diametrical mortise with a cutter *c*, notched out to take the flattened sides of the bar, secured with a wedge *w*. As the Cornish bit is used on the lathe it is only supported by the work at one end, and the poppet-head at the other, therefore a bearing piece *b* is fitted in a chamfer groove or under-side of stock, as shown detached, to keep it central. The three edges (cutter and bearing piece) are all turned in their places, and the cutter is levelled and rounded so as to cut at the front only, after which the parts are hardened. These bits are made for holes larger in diameter than $\frac{1}{16}$ in., and every stock may admit of an increase in size up to $\frac{1}{2}$ in., and larger sizes

in proportion. Messrs. Maudslay's boring bits with loose cutters are represented in Fig. 11, and range from 3 to 12 in. in diameter, with a power of variation in size. The stocks of the smaller sizes are of wrought iron, the larger in cast-iron, the cutters rest in contact with a fillet made on the stock at right angles to the axis, and held down by screws passing through mortises in the cutters, to enable these to be set out to various diameters. The bearing piece, though generally fitted in a chamfer groove, is also made to admit of setting-out packing to make the points of bearing fall in a circle similar to that to be bored. Mr. Stevens' lathe drill is shown in figs 12 and 13. It has two cutters, adjustable for various diameters, and is intended to be used with the loop. The cutters *c c*, lie in oblique grooves, the ends of which are at an angle of 45° , and between them is placed a wedge *w*, the shaft of which extends through the entire length of the drill shaft. When the wedge is set forward (by tail screw and nut) the cutters are thrown out as desired, so that the bit for $\frac{1}{16}$ in. holes may thus be enlarged for any size not over $\frac{1}{4}$ in., and so with the larger tools. The cap plate *p*, *p*, is attached by three screws, and has a shallow recess within which two pins fixed in the cutters are loosely contained to prevent loss. The cutters have their ends rounded, and sharpened as in fig. 3, and the two edges of the shaft, marked from *a* to *b*, are made symmetrical and with rectangular edges, for the loop, from which this drill receives its axial guidance. Mr. Kittoe's expanding half round bit, figs. 14, 15, 16, have three parts instead of two made to adjust radially and equally. The tool is used as a common half round bit, from the one point only being sharpened, and there being a bottom bearing upon

cylindrical—a little less behind, and its end is cut into teeth like a countersink. Fig. 3 is employed mostly for cast-iron work. The blade end is made nearly parallel, the two front corners having a slight rounding and chamfered, which chamfer is continued at a lower angle as far as two diameters in the length: this part is not parallel, but slightly lapped in the middle. It may, by proper direction, cut sideways, making the hole larger than intended, but when the hole has been roughly bored to its proper diameter by a common fluted drill, the bit, Fig. 3, is then placed through the stay, as shown in Fig. 4, lightly supported between the chamfer on the work and the poppet-head centre; the moment any pressure comes on the drill its opposite edges stick into the inner side of the loop, which thus retains its position. The drill and loop should be exactly central, and fig. 4 shows the common form of the stay fitted to the lathe rest; but it is sometimes made as a swing gate, to turn aside whilst the work drilled is removed. Cylinder bits may be used for enlarging holes below half an inch to a third their diameter at a cut, and from holes up to an inch to about one fourth their diameter or less: and as the size of the bit increases the proportion of cut to diameter should decrease. As the cylinder bit is not intended to be used for drilling holes in the solid material, the following course should be adopted: a drill, fig. 5, say $\frac{3}{16}$ in. diameter is first sent in to the depth of an inch or more, and the hole enlarged by cylinder bit of $\frac{1}{16}$ in. diameter. The centre at end of hole is then turned by fig. 6, a re-centring tool, the plug of which just fits the hole made by the cylinder bit; the end of the drill, fig. 6, then acts as a fixed turning tool, correcting the centre if not previously made true. Another short portion is then drilled with fig. 5, enlarged with the half round bit, and again corrected with

the surface of the hole that is bored. Fig. 14 shows the boring bit in condition for work. Fig. 15 is a horizontal section of the same, and *a* to *k*, fig. 16, are the parts shown separately. The part *c* to *g* is of brass, and contains all the mechanism; *g* to *h* is an iron rod screwed into the brass as a shaft, of any length required. From *c* to *e* is in two pieces, which separate nearly on their diameter, and are united jointly by steady pins, and the screwed nut *d*, the division being made to allow of the introduction of the two bits *a*, only one of which cuts; *b*, the bottom bit, is inserted in a similar but vertical cleft. The central wedge *i* advances the three bits equally and simultaneously; this wedge is conical, reduced to form three fins at right angles to one another, that enters the groove for the bits; this wedge is set forward by the tail screw *K*. There is a side screw to prevent movement by this set screw *K*, which is only comestable by removing the socket *c* *g*, from the stem *g* *h*. If the wedge with its fins were advanced somewhat beyond its present position it would stand before the cutter, and keep the tool from getting to the bottom of the hole; to

free it of air. It should also have mixed with it about 1-500 of crystallized sulphite of soda to prevent it oxidizing the iron parts of the apparatus. After closing all joints to cut off communication with the exterior, the apparatus is freed from damp. For this purpose there is fitted over the opening *f*₁ of the generator caoutchouc pipe carried from the bottom of a vessel filled with sulphated pounce; the apparatus is set gently to work, and the air drawn, it escapes from the opening *g* of the condenser. A glass tube, charged with a small quantity of caustic potass, shews the state of dryness of the current of air. The air has now to be expelled from the tubes and receivers by driving in the vapour of some frigorific agent, which may be ammonia, sulphurous acid, or hydrochloric ether; say we take ammonia, the vapour of which is lighter than air. Two flexible tubes are fixed upon a drying vessel full of caustic potass, and in communication at bottom with an impermeable bag charged with a weight, and continually fed with ammoniacal vapour cooled to zero. The ends of these flexible tubes are fitted on the cock *θ* of the suction tube *I* and of the conducting tube *D*. The

place successively, but for this purpose it is necessary that the temperature of the condenser should not rise, notwithstanding the redisengagement of latent caloric freed by the liquefaction produced, and that is the object which this apparatus fulfils; the sensible heat freed by the liquefaction of the vapour is suppressed by the vaporization of water on the outer surface of the condensing tubes. The upper ends of the nets which dip in the vessel *B* formed at the upper extremity of the condenser being once primed with water, the cambric lining is uniformly damped over its whole extent by capillary attraction, the draught which traverses with rapidity the space marked by arrows, as well as the heat from the condensation of the vapours, vapourise the water, and this evaporation absorbs the excess heat. This method of cooling by draught is based on the same principle of producing cold by evaporation, and has the advantage of economising refrigerating water, and also of economising the mechanical work by lowering the temperature to the lowest natural temperature of the current of water. When the condensing receiver is full of liquid up to half the

avoid this the back edges of the cutters are made at the same angle as the wedges. The cutters have oblique mortices which pass over the holding pins in the semicircular piece, and prevent the cutters being lost, which they sometimes "mysteriously" do.

COOLING AND FREEZING.

(Concluded from page 74.)

To shew how the apparatus acts as a regulator:—Let us suppose partial escapes, and too little water in the cylinder, the piston *a* rising, the mercurial piston going down the valve *u*, floating on it, closes the chamber *o*, and the rest of the apparatus stops. The piston continuing to rise, a vacuum taking place in the pump draws the water which penetrates through the leather, and fills the body of the pump. With a stuffing box an additional valve would have been necessary. The safety valve prevents the water entering in excess should the cooling be pushed too far. As to the compression chamber provided with a second valve *u*, its object is to prevent the passing of globules of mercury, it only comes out when the apparatus is working with air, for example, to dry the interior of the tubes and of the receivers. All the pipes and receivers should be tested to ascertain their powers of resistance, and to detect the least leak. The water before being introduced into the pump should be boiled in order to

vapours pass to the generator by the passage of the cock *h*, which is open, and replace the air which is expelled by the orifice *f*₁. Then the apparatus is allowed to work for some minutes to clear or purge the interior of the pumps and compression chambers, the expulsion is effected by the orifices *S*₁, *S*, formed in the compression chambers, and the machine is closed or stopped.

When the cock *π* of the conducting tube *D* is opened, the ammoniacal vapours pass into the condenser by the passage of the cock *C*; the air is expelled by two orifices formed in *S*₁ at the bottom of the tube *D* and in *h*₁, furnished with a cock in which terminates the discharge tube, plunged in the condensation receiver, and indicated in the drawings by the dotted lines *a*₁. The tube and receiver are then perfectly freed from air. The orifices *S*₁, *S*, are closed, and then is fitted to *h*₁ the end of the tube *m* in communication with the feed cock *C*. The apparatus is allowed to work for some seconds, the vapours finding no other outlet, the cock being re-closed, are expelled through the feed cock and escape by the tube *g*, driving the air before them; when this last operation is finished, the end of this tube is fixed on the orifice *f*₁, and the machine continued to be worked. The vapour driven back successively into the condenser is compressed more and more, the center of the manometer advances progressively towards the division which indicates that liquefaction has commenced. The changes of state take

level gauge *l*, the cock is opened which closes the orifice *f*₁, and the congealing fluid commences to enter in proportion into the generator by the regulated play of the feed cock *C*. In order that the level *l* may remain invariable, the duration of the action of the feed cock is modified as may be found necessary. The level of liquid is raised in the generator up to half the glass indicator *l*. The cock *θ* is first closed and afterwards the cock of the generator *h* opened, and the apparatus is ready for use.

When the apparatus is in work the pumps being fed this time directly from the air in the generator, in proportion as the tension of this air diminishes in the dome *F*, the volatile fluid disengages from its mass a fresh quantity of vapour to saturate the space, at the same time a proportionate quantity of sensible heat is absorbed in a latent state, and this quantity of heat, equivalent to the caloric of elasticity due to the change of state, not being compensated by a constant source, the evaporation is maintained at the expense of the heat of the surrounding bodies, and the refrigeration of these bodies is the more intense as the vaporization is more rapid or prolonged. The result is that the fluid circulating in *N* is exposed to the refrigeration which furnishes all the heat, and consequently the temperature of *N* is lowered; *N* loses all its heat and becomes a source of cold, which cools in its turn the bodies exposed to its action.

In the manufacture of ice the first process is a

ollows:—It is a mechanical operation consisting in congealing the water in a constant and continuous manner by the circulatory movement of a refrigerating medium, and in depositing the ice as it is formed. A layer of ice is thus always separated from the water to be frozen, and is therefore not opposed to the diffusion of the heat which it is necessary the water should lose. Fig. 3 shows the apparatus in vertical section, and figs. 4 and 5 in plan.

a is a chamber in which a generator *b* is placed; it is covered by a second chamber *c*, open at front and divided into two compartments *d*, *e*; in the bottom of *d* two openings are formed, one of which gives passage to the dome *f* of the generator, and the other, which is furnished with a pipe, receives the body of a screw propeller *g* resting on a pivot, so as to turn freely round its vertical axis; toothed gearing *i* transmits the motion to the shaft of the cock *j*; a metallic disc *k* covers the compartment *d*, and allows passage to the upper part of the dome and the propeller rod. The compartment *e* receives the ice *l*, it is composed of a metal cylinder supported by two pivots, *m*, *n*, the ends of the cylinder which are narrowed are supported in bearings, and terminate in pipes *o*, *p*, the pipe *p* communicates with the generating chamber and the pipe *o* with the propeller chamber; stuffing boxes *q*, *q'*, allow the cylinder to turn without there being any loss of the liquid in circulation; the uncongealable liquid which circulates in the interior of the machine is a mixture of one part alcohol and two parts water, which has the advantage of not deteriorating as saline solutions the metallic parts; the bath being completely enclosed there is no loss.

A toothed wheel *r*, fixed to the end of the cylinder, gears into a wheel *s*, which receives motion from the spindle of the cock; *t* is a steel scraper of prismatic form fixed on supports, following the longitudinal direction of the cylinder, and in a direction opposed to its movement, so as to be directed tangentially against the length of the circumference of the cylinder, and on the lateral faces being free to slide as a carriage on its support, and being held by pressure screws at any desired distance. The pieces *u*, *u'*, which form a right angle with the scraper, is connected by binding screws; *v* is a trough of tinned copper, in which part of the cylinder dips; it is constantly fed with the water intended for freezing. The whole machine is enclosed in a double wood casing *z* fitted at its upper part with a cover and at front with a shutter.

The machine being arranged as before described, when rapid rotary motion is imparted to the propeller in the direction of suction, the uncongealable liquid being confined in the generation chamber answering to the attraction produced by reaction, an ascending current is formed, but as soon as the liquid is precipitated into the propeller chamber, the contents of the latter traversing the cylinder *l* by the pipes which correspond is driven into the propeller chamber and replaces the displaced liquid, and consequently during the time the propeller is worked, a correspondingly rapid circulation is kept up in the cooling apparatus.

The cylinder *l* being put in motion, let us suppose the liquid which circulates therein is cooled 4°; the cylinder which in touching the water in the trough congeals it, and becomes covered with a layer of ice; the scraper *t* removes this ice, which is deposited in powder in the ice chamber *e*. A cock *y* and overflow *z* allow of a constant level being maintained in the trough; the water which falls drop by drop by the overflow orifice, indicates that the trough is fed in proportion to the transformation of water into ice. The product being strongly packed in wooden cases, is formed into blocks of ice.

NEW MINERAL.

A new mineral of lead has been discovered in Chili, containing 10 per cent. of iodine. Iodine has lately become very valuable, on account of its extensive use in photography, and of the discovery, by Dr. Hoffman, of a new dye, having this element among its constituents. It is said that one cargo of the new mineral will represent a fortune. As a further illustration of the progress that mining adventure is making in South America, a mine of bismuth ore has recently been opened in Bolivia, about two-thirds up the highest of all the peaks of the Andes—the Iljampu Mountain. Bismuth, also, has lately increased in value; and 15,000 feet above the level of the ocean, only slightly beneath the line of perpetual snow, men are setting to work to obtain it.

TREES, &c., which fall into the pitch lake of Trinidad soon become true coal.

THE SOHO WORKS, BOLTON-LE-MOORS

From the Engineer.

Amongst the engineering works which may almost be said to have grown with the growth of engineering itself are the Soho Works, Bolton. From this establishment have been sent, during the last thirty years massive stationary engines, many of them working in parts of the globe where, before their erection, steam power was only known by hearsay. It may be termed an off shoot from the Union Foundry, of the same place, which has been at work since the beginning of the century. The Soho Works were founded in 1833 by the late Mr. Benjamin Hicks, who though he died at a comparatively early age, has, it need scarcely be said, left behind him a prominent name amongst those early mechanical engineers who were the real creators of modern engineering. It was on dissolving partnership with Mr. Rothwell, the only survivor of the original partners in the Union Foundry, that the late Mr. Hicks began to lay down the present works. The site chosen consisted of six acres of land adjoining the station in Bolton of the London and North-Western Railway Company. As is almost necessarily the case with workshops whose long existence has been attended with commercial success, the requirements of different periods, and the necessity for extension, within certain given limits, have since led to many departures from Mr. Benjamin Hicks's original arrangement of the buildings. For a certain length of time the shops could also evidently be increased according to a definite and settled plan; but in the course of years this became more and more difficult, until we see the rather irregular block of buildings into which the workshops of an old and extensive firm generally get merged. Nearly eight hundred men, who have worked overtime for years are employed at the Soho Works in manufacturing the large stationary engines and boilers, the heavy water wheels and more modern turbines, the millwright work generally, which form the present staple manufacture of the firm.

At another part of the town is an extensive forge and steel works, adjoining each other. In the first of these are a number of puddling furnaces and hammers, and it is here where the heavy forging for the Soho Works are made. In the Bolton Steel Works, adjoining the forge, are erected two 5-ton Bessemer converters. Powerful hammers and rolling mills are now being erected for working up the steel. From five to six hundred men are employed in these two establishments, in which Mr. Hick, of the Soho Works, is one of the partners; the managing partner being a son of the late Mr. John Sharpe, of the well-known Atlas Works, Manchester. Here are also rolled the Bessemer steel boiler plates, largely and successfully used at the Soho Works. Each plate has its edges cut in a large shearing machine, one of the resulting crop ends being always bent double in order to test the equality of the material of each plate. The ductility of the material was remarkable, and it seemed to be the very stuff for boiler making. The other arrangements of the works were of the usual character adopted for puddling, forging, and rolling.

In the good old times, when there were comparatively few engineering shops in the world, before mechanical engineering had thrown off so many separate off-shoots, and before these causes, added to the present severe competition, had divided the trade into determinate special branches, the late Mr. Hick seems to have taken a pride in turning out the most varied work. Locomotives, marine engines, machine tools, and many different kinds of manufacturing machinery, used to be made here. But marine engines are now almost solely, and at any rate most profitably, made close to where the hulls they will drive are being built; while the fact that locomotive orders are generally given for a number at a time permits the adoption of special arrangements and tools, of, in fact, special factories, such as, for instance, the Gorton Works, which do not permit the competition of establishments like these, which are more suited for the manufacture of heavy stationary prime movers and their millwright gear.

Walking through the works we see—very complete arrangements for making the large details of heavy stationary steam and hydraulic prime movers. Amongst the machine tools is thus the large vertical boring machine which, when first constructed some years ago, attracted much attention. It consists of three distinct machines, for boring, drilling, and face-grinding, respectively. Four columns support an entablature carrying the upper parts of these three different machines. In the centre is the machine for boring cylinders up to 95 in. in diameter and about 10 ft high. They are fixed on movable supports in the usual way by clamps, and are also

steadied by a circular frame able to slide up and down. The smaller boring machine used to be employed for boring out such work as cranks' centres, but it is now found more convenient to do this kind of work in a rather more accessible and independent machine. The smaller tool on the other side of the large boring machine illustrates the progress of different modes of work, and the introduction of scraping instead of grinding. It was designed for grinding up the faces of piston rings and of similar work, which was fixed on the table as if being bored, while a vertical bar drove the grinding plate; such work is first faced up in the lathe and then scraped up, a very slight grinding by hand, with emery and oil, being resorted to at the end of the process.

Of a somewhat similar character in its way is the large planing machine, designed many years ago by the late Mr. Hick, for planing large cast iron plates for glass casting. Old as it is, however, it was only a few weeks ago that an American engineer, in the course of a visit to these works, stated that he had re-invented and patented a planing machine after the very same plan—a coincidence which he only accidentally discovered after having sacrificed much time and money. The peculiarity of Mr. Hick's machine, once a wonder in its way, consists in making the tool move while the work remained stationary. It will take in a plate 30 ft. by 12 ft., and is also able to receive a cylinder of 400 horse power in order to plane up the valve-box flanges and the other surfaces. The framework is formed of two longitudinal side pieces, on which rest the cross slide pedestals carrying the cutter box. We understand that the cross-slide consisted at first of a round bar, able to slightly oscillate the cutter box holding two tools—cutting each way, and alternately raised at each return stroke by the oscillation of the bar on the axis. To the cross bar carrying the tool are attached levers, one on each side, to which were connected endless steel belts passing over pulleys at each end of the machine. One set were the drivers, the other set the carriers; the friction upon the first being sufficient for the heaviest cut. As the belts moved the cross bar backwards and forwards at the return of each stroke, the oscillating motion was given to it, limited by two set pins. The machine is now fitted with one of Mr. Whitworth's revolving tool boxes.

Near the heavy vertical boring machine we spoke of first, is a lathe, with a 10 ft. face-plate, capable of boring up to 16 ft. diameter. A convenient plan, requiring only one setting, is adopted for boring out the eyes of engine beams. The beam is simply fixed on a table sliding in V slides, similar, in fact, to a planing machine table, the boring tool being worked in an ordinary vertical boring machine. This machine is also found very convenient for other work. A tool of, to us, rather novel form is used for facing up such work as the valve chests of large cylinders. It was designed by Mr. John Hick, C.E., the present senior partner of the firm, and it may be styled a sort of composite tool between a slotting and a planing machine. The tool box is fed down vertically, being worked to and fro on a planing machine bed, while the work is set on a fixed table, the longitudinal axis of which is at right angles to that of the pair of V slides on which the tool box is worked. On the millwright's side of the establishment, where, I other but engine work is done, the separate arms of the large fly-wheels are fitted together over pits, within which one half of the wheel can turn. A lathe can thus be easily extemporised and fixed up at any diameter, and against the tool of which the wheels may be turned up. In the smaller pit, in use at the time of our visit, was being put together a spur fly-wheel 26 ft. in diameter. The teeth of these wheels are never, in this establishment, cast solid on the iron rim. Such wheels, with the teeth on a separate outside rim, are found to wear much better, being free from the effects of unequal contraction, produced when the teeth are cast together with the main rim. Wooden packings, into which thin iron wedges are afterwards driven, are placed between the ends of the segments. All the boilers made there are, of course, systematically tested by hydraulic pressure, for which purpose is set up a pair of force pumps which can be driven from the shop engine by means of a belt. The smaller machine tools are placed in a storey upon the ground floor on which are the heavier machines. In order to be able to clear away the columns which would otherwise have to support a floor eighteen yards wide, and to thereby afford room for the heavy cranes on the ground floor, the flooring of the first storey is suspended from a number of slender tie-rods, attached to cross beams in the masonry. These smaller lathes and machines are of the usual descriptions.

(To be continued.)

BIRTH AND GROWTH OF THE IRON TRADE.*

By JAMES ROBERTSON.
(Concluded from page 80.)

I do not deem it necessary to explain at any length the process of the manufacture of hot-blast pig-iron, as you are already well acquainted with it, further than asserting that in some instances the heated air driven into the furnace is obtained from a series of chambers constructed round the mouth of the furnace, deriving their heat from the blast which smelts the iron, and thereby economising the fuel: but more generally the heated air is drawn from chambers heated by a separate furnace, as any desired temperature can be obtained therefrom, and that altogether independent of the flame of the iron furnace, and at a very trifling cost. There is a great preference given to cold blast iron where castings require to possess a smooth and hard surface, but where fluidity of the metal when molten is necessary to bring out the fine details of a casting the hot blast pig is decidedly preferable to the cold blast. The presence of a large proportion of carbon in these pigs is the cause of their fluidity, and the principal object of the process of refining, when malleable iron is to be made, is to eliminate the carbon, and render the iron close and fibrous. It may not be uninteresting to give you a statement of the actual weight of material necessary to produce 1 ton of pig-iron. It is as follows:—

Raw Mine.....	3 tons 10 cwt.—2 tons 4 cwt. of iron ore.
Coal for furnace.....	3 tons 0 cwt.—2 tons 5 cwt. of coke.
Do for kilns, engines, &c. 1 ton 0 cwt.	
Lime as flux.....	1 ton 0 cwt.
Total.....	8 tons 10 cwt.

Thus presenting a total weight of material of 8 tons 10 cwt. for every ton of pig-iron raised; and before this ton of iron reaches the condition of manufactured there will have been expended upon it a quantity of raw material equivalent to a weight of 14 tons 10 cwt. The manufacture of iron in Scotland had been behind that of the southern part of this island, but the discovery and general adoption of the hot blast produced the most extraordinary development in her production. In 1815 the quantity produced in Scotland was 475,000 tons; that production gradually increased till, in the year just closed, it reached the enormous amount of 950,000 tons for Scotland alone; and the production of the whole of the blast furnaces in Great Britain and Wales gives a total for the last year of 5,600,000 tons. Here is a source of internal wealth; here is a production in iron equal in value to the annual imports of gold from Australia, even taking the value of the iron at a low figure, in round numbers; a source of wealth for the development of which we require no external aid, a wealth raised by the diligence, industry, and perseverance of our mining workmen, stimulated by the enterprise of capitalists; a source of wealth secure from attacks from without, so colossal as to require no protective duties, so abundant that all foreign states shrink from competition, and defend their own monopolists by prohibitory rate; and yet, although we once did the same, and were obliged to import iron for agricultural and engineering purposes, yet that period has long since passed; competition has taken the place of monopoly. Free trade has received, as regards iron in this country, a complete justification of its principles. We do not exclude the foreigner from our markets, but he excludes us from his; besides, he levies an export tax, which our Government has long since abandoned, and he will neither buy in our markets nor let us buy in his, even if we could do so at a profit. The iron produce of the whole world is only equal to about two-thirds of the produce of Great Britain alone. You may, therefore, say that we may well afford to be liberal in our commercial policy; but consider this, that the greatness of our production has arisen from the absence of an exclusive commercial policy, and the desire of our ironmasters not to exclude foreign material by protective duties, but by the superiority and facility of our production, and to these principles and our restless activity in discovery is the present greatness of the iron trade attributable.

France has hitherto produced a most inconsiderable quantity of iron in proportion to her population, it is not equal to the produce of South Staffordshire alone, being only about 800,000 tons: there are many ironworks in France, of which the most important are Cresot, Fourchambault, Hayange, and Voeges; there are several groups of iron works in the north-east, north-west, in the Indre, and La Vendée, and groups of coal fields in the south. But a narrow and prohibitory policy has hitherto restrained the ironmasters from developing the re-

sources of the country, and not only the masters, but the workmen in the mining districts of France, look upon anything approaching to free trade in iron with foreign countries, especially England, as the death-blow to their industry. It must not be supposed that the raw material does not exist—it is found in abundance—but not in juxta-position, as in England.

Mr Perdonnet, in his report to the Societe Institution, said that "France has an inexhaustible supply of minerals, excellent in quality, and most of them equally rich with the English minerals. There is pit coal in abundance, many kinds yielding excellent coke, well suited for the blast-furnace, costing less at the mine than English coal, except at a very few places. Limestone and fire-clay are to be had at the quarry equally cheap, and the labour costs less in France than in England." But the coal, ironstone, fire-clay, and limestone being all found in different localities, and there being no canals or railways to bring the raw materials together, the expense of transit becomes so great that more than a third of the value of the iron is eaten by the expenses of the carriage. At Fourchambault, the coal of St. Etienne, which costs only 5f. (4s.) at the pit's mouth, has increased by the outlay of carriage to the ironworks to 30f. (24s.) per ton. So you see this item of carriage becomes most serious when it requires so many tons of coal to make every ton of iron, and one which must materially add to the cost of the material; that is only one instance of many similar cases. But this defect is being daily remedied; locomotion by railways and canals is daily becoming more easy. The commercial treaty with France strikes £2 per ton off the duty on bars.

The policy of France with regard to iron has been till now what ours was up till the year 1825, when the duty was abolished, though not without opposition from several of our ironmasters; and if France attains so great a development, commencing from this date, as we have done from the date of the abolition of our import duties on iron, what must be the amount of its production in a few years? Depend upon it, we shall not stand idle. The foreigner may tread upon our heels, but the touch will only be the signal for a new bound, and he will be distanced. Continental engineers now produce works of engineering skill which demand and receive our praise. The workshops of Paris, Mulhouse, Vienna, and Berlin are no contemptible establishments, and an Englishman beholds with gratified pride that the machinery and tools in use there either bear the name of one or other of our makers, or are modified from an English type.

The annual make of iron in Spain is estimated at 8000 tons, a contemptible quantity for a country rich in minerals, and having a population of some 15,000,000. Sweden and Norway have long been celebrated for their iron mines. The cause of the superiority of Swedish iron has never been accurately ascertained; it has been attributed by some to one cause, by others to another—such as the manner of working, the presence of manganese, and, with a great amount of probability, to the superiority of the mine in the first instance. Large quantities are exported annually from Sweden for conversion into steel, but the whole exports do not exceed 80,000 tons per annum, and the production of unmanufactured iron is about 150,000 tons. Belgium is a rapidly thriving iron district, but its produce is limited; however, in a few years it may do wonders, as its mines are worked with great intelligence and skill. It will be impossible in a sketch like this to detail the histories of the iron trade in Russia, Prussia, Austria, and the States, even if it were desirable to do so; but I may remark, if you will permit me to use a double Hibernianism, that Ireland is the only part of England which, as regards the trade, has advanced backwards. In 1672, 1000 tons of iron were made in Ireland; now, with one or two exceptions, the manufacture has ceased.

I find that the number of operatives engaged in the manufacture of iron, including those employed in the kindred operations of quarrying and extracting the minerals, is 250,000 men, and in giving motion to the various machinery requisite for the creation of iron there are steam-engines of an aggregate force of 250,000 horses, equal to 1,000,000 men, so that altogether we have a force in this country devoted to the production of iron equivalent to that of 1,250,000 men, entirely exclusive of the manual labour employed in engineering operations. Our exports of iron, machinery, and cutlery, in declared value at the Customs, amount to £5,100,000, whilst our imports of iron amount to only £35,000, nearly the whole of this amount being paid for Swedish iron.

It was in 1740 that the iron trade was so low and languishing; it was at its greatest depression, when

suddenly it began to rise; though apparently lifeless it suddenly sprang into new existence. It was at this time that improvements in the manufacture of this metal, and the increasing wants of society, raised its drooping head; it was at this time that agriculture, one of the iron trade's best supporters and friends, came to its aid. The cumbersome wooden plough, which for ages tilled the soil, began to disappear. Agricultural implements of iron began to be used, the wheelless waggon began to be disused, iron tyres were adopted for the wheels of vehicles more generally, and the production of iron for the trade caused no inconsiderable increase in the consumption of its own production; but whilst the plough was being made of iron the sword was not forgotten. The implements of war were being fast improved, the cannon of the navy, and the armies of England were being augmented to an extraordinary degree. The tonnage of the ships of war was being increased, and with the increase of tonnage came guns of greater calibre, of heavier metal. The war of the Austrian succession was at this time raging. Russia was fighting with the Turks. The American colonies were clamouring for independence, for at that time America had not thrown off the yoke of England. The political atmosphere, as the phrase now goes, was at that time very clouded: the something "looming in the future" which Mr. Disraeli's telescopic eye saw a few years ago was most distinctly visible then, so England prepared to have a shot at it, and she hastened to complete her armaments by sea and land. Besides, there was rebellion in our own land; the last efforts of the Jacobites were made about this time. The Pretender (Charles Stuart) had landed in Scotland, and it was in 1746 that the battle of Culloden was fought, which extinguished his hopes and claims to the throne. So you see that those were busy and stirring times, and it is well known to you what an impulse a popular war gives to the iron trade. The note of preparation sounds with increasing clamour, the anvil is never vacant, the hammer never idle; there are tempting contracts out, the artisan is in great request, Birmingham is extremely brisk, and at such a time Brown Bess had many suitors.

Yet, whilst war and tumult were active commerce did not slumber. The great bugbear held up by foreign nations to deter England from war has always been the paralysing of her commerce, yet it has seldom chanced that England has suffered from wars, as her commerce if restricted in one direction has generally expanded in another, and we have seen our exports and imports increase in spite of all the threats and forebodings of our enemies; and however the tide of battle may have risen or fallen upon the Continent, the ocean, the great highway of our commerce has been free and safe wherever our sails were spread upon its boundless bosom.

During the first half of the last century cotton goods formed the principal items of our exports, and next to cotton in importance or declared value came hardware and cutlery. It was about the year 1770 that cotton began to be an important native production as an export, but since that time the extension and improvement in the cotton manufactures has been so great that at this time the exports of cotton stuffs and yarns amount to nearly an entire half of the total exports of British manufactures; this is attributable to the great improvement in their manufacture by the employment of machinery, and which machinery owed its existence to the iron trade. The exports during the year 1784 amounted to a little over £15,000,000 in declared value, the British manufactures and produce being estimated at £11,550,000, the balance of the £15,000,000 total value being foreign and colonial produce. In 1785 they increased by £1,000,000, the increase being on the side of manufactures. There was a corresponding increase in exports till 1790, when the value amounted to £20,121,000, the value of British manufactures being in that year £15,000,000. The same steady increase goes on up to 1818, when the exports reached £45,180,000, the value of our exported produce and manufactures being in that year over £45,000,000. There was a great development of our commerce and manufactures going on during the whole of the French revolution and war, embraced in the period from 1770 till 1818.

The day from which the greatness of the cotton manufacture of this country dates is the 15th of July, 1769, the day on which Richard, afterwards Sir Richard, Arkwright took out his patent for improvements in the manufacture of cotton. Arkwright was born of poor parents, of whom he was the thirteenth child; he had no capital but his intelligence, perseverance, and indomitable power of will, but he was one of the most distinguished members of that band of inventors, those men of practical

talent, by whom the manufacturing system of the British empire has been brought to its present state of excellence and superiority; he was born at Preston, in Lancashire. There were no manufactures of cotton there before his time. He was by trade a barber. So intent was he on perfecting his invention that he was often long absent from his business; his wife, one of his own humble sphere, dreaded lest the business should go to the dogs, and she and the family to the workhouse, broke his models in the hope of curing him of what appeared to her to be a delusion, and refixing his thoughts upon his powder puff and pomatum pot, but in vain; he completed his invention after a labour of nine years, and it is to him the cotton trade owes so much. The merits of his improvements are fully detailed in Mr. Baines's history of that trade. Now, it will naturally suggest itself to you what a great impulse the application of machinery must have given to the iron trade, when you consider the vastness of its productions, and the value of its exports, as shown above. Arkwright's machinery was now employed in a thousand mills; the ceaseless looms were working day and night, but the prejudice in the minds of the workmen was great against the employment of Arkwright's inventions; the handloom weaver looked upon them with dismay, and saw nothing but his ruin in their employment, so little were those great principles now so generally understood—the doctrine that the employment of machinery in the productive sciences increases the demand for the labour of the industrious classes, the great fact that the manual labour of this country is by no means adequate to our productions without mechanical aid, and that if the cost of the manufacture were reduced by such means the demand for the material produced increased in proportion to its cheapness, and made this country a successful competitor in foreign markets with the productions of foreign nations, creating an increased demand for the labour of our artisans. The artisans of that time had little faith in the natural growth and development of society; they did not see that new wants would arise, that artificial desires and necessities would be created, which manual labour could never supply, but they looked upon machinery as their natural enemy, in much the aspect as the window-breaking urchin regards the policeman. Riots took place, and the machinery was burnt or destroyed, so blind and suicidal was the animosity raised against it.

INSTITUTE CHEMICAL SOCIETY, BIRMINGHAM.

LECTURE ON STEAM BOILERS.

On Thursday last an interesting lecture on the above subject was delivered to the members by Mr. M'Evoe.

Before proceeding to the subject of steam boilers, Mr. M'Evoe gave an account of the new theory, in relation to the means by which masses of water become heated, propounded by Mr. Williams, of Liverpool. He first gave the old theory, supported by Brande, Graham, and most of the philosophers of the last half century, which was that called convection, and was explained thus:—When any source of heat is placed at the bottom of a vessel containing water, the stratum of liquid at the bottom became heated, and, consequently, specifically lighter than the upper stratum, and rose to the surface, that at the top falling, and becoming in its turn light, and so on, until the whole of the liquid has arrived at a temperature of 212°, when it is dispelled in the form of steam.

It was set forth that water was incapable of conducting heat, and that the mass of water becomes heated by convection, or a carrying of the heated particles upwards, and the cool ones down to become heated in their turn. This theory is usually illustrated by suspending small solid particles in a globular-shaped vessel, and applying heat to the bottom, when the motion of the solid bodies indicates the current of heated water. But, recently, this theory has been considerably shaken by one set forth by Mr. Williams, which supposes that as soon as heat is applied to a vessel of water, vapour is at once produced, which is gradually absorbed by the water until the heat of 212° is reached, at which point the water is saturated, and the vapour escapes as steam. In support of this theory, Mr. M'Evoe performed the following experiment. A small test tube was half filled with water, and a watch glass was placed over the mouth convex side, downwards, the concave side being partly filled with water. When the test tube was held in the hand vapour was given off, and condensed on the lower side of the watch-glass; this experiment proving that steam is generated on the application of the slightest heat. Another experiment was performed to demonstrate

the same fact, and also to show that water is incapable of condensing steam; it was as follows:—A large glass beaker was about half filled with water, a small stool was placed in the centre, and upon this a watch-glass, concave side downwards; upon the application of heat supplied by a small spirit lamp to the bottom of the beaker, vapour was produced, and collected in the watch-glass until the amount was sufficient to overturn it.

Mr. M'Evoe then proceeded to describe the various forms which steam boilers have assumed. 1st. The dome shape, which was used for a short time by Watt, and soon gave way to the waggon shape, which had the disadvantage of being the worst shape that could be devised for strength, often requiring bars of iron to prevent the sides and bottom from being forced out of shape, these being the weakest parts.

The Manchester boiler was mentioned as being the best for economy of fuel and greatest strength, the dimensions for a 20-horse boiler of this kind being 20 feet long, 5 feet wide, and 6 feet deep.

The London boiler (in which the fire was placed inside, and completely surrounded with water) was considered by many as the best form, but the lecturer (who is, by the way, a gentleman possessing much practical experience) mentioned some important defects. He stated, that in this form of boiler the flame does not impinge directly upon the surface; but is carried along transversely to it, thereby dispersing much of the heat. Mr. M'Evoe mentioned some experiments made upon a locomotive pipe boiler, which proved that the first foot from the source of heat generated as much steam as the rest of the boiler, he accounted for this by the fact that the flame impinges directly upon the face plate, and heats the tubes nearest to it; but, during its passage through the rest of the tubes little heat is produced.

A cordial vote of thanks was presented to Mr. McEvoe for his very interesting lecture, which brought the meeting to a close.

PATENT LIST.

(From the Commissioners of Patents' Journal.)

LIST OF SPECIFICATIONS, &c. PUBLISHED DURING THE WEEK ENDING 4TH NOVEMBER, 1865.

- 3233. Patenting for railways, M. A. Muir and J. McIlwham—10d.
- 3234. Float for steam boilers, J. Truwell and W. Truwell—4d.
- 3235. Separating wool from refuse mixed fabrics, A. Saville—4d.
- 3236. Manufacture of pins and needles or gills, T. R. Harding—1s. 2d.
- 3237. Mules for spinning and doubling, J. Doid—10d.
- 3238. Sewing machines, J. H. Johnson—8d.
- 3239. Steam engine, &c., W. Nalder and A. Belcher—1s. 4d.
- 3240. P. o'jectiles, R. Call—4d.
- 3241. Warehousing or storing liquids, &c., P. C. P. L. Prefontaine—10d.
- 3242. Machinery for manufacturing enamelled wares, B. Baugh—1s.
- 3243. Girders, K. Shuffelbottam—10d.
- 3244. Globes, E. Fere—1s.
- 3245. Burners for hydrocarbon lamps, A. S. Macrae and A. Bayley—4d.
- 3246. Hair-brushing machinery, A. C. Robb—4d.
- 3247. Motive power, R. Comprant—4d.
- 3248. Horse-shoes, H. A. Bonneville—8d.

3249. Presses, H. A. Bonneville—4d.
 3250. Roof, T. Bouch—1s. 2d.
 3251. Cast steel tubes, W. H. Brown—1s.
 3252. Treating oils and hydrocarbons, L. P. E. Max—10d.
 3253. Carding engines, J. Laidley—8d.
 3254. Machinery for making horse-shoes, W. E. Newton—10d.
 3255. Smoke-consuming furnaces, F. A. Royer—8d.
 3256. Maure, T. Richardson—4d.
 3257. Printing music, F. J. Endres—4d.
 3258. Cases for jewellery, &c., K. Quin—8d.
 3259. Manual power carriage, T. du Boulay—10d.
 3260. Obtaining and applying motive power, C. W. Siemens—4d.
 * * * Specifications will be forwarded from the Commissioners of Patent Office, Southampton-buildings, Chancery-lane, by post on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post-office Order, made payable at the Post-office, 5, High Holborn, or Mr. Beckett Woodcroft, her Majesty's Patent Office. We cannot undertake to forward Specifications, or books advertised from the office of THE ENGLISH MECHANIC.

PRINTING PRESS MANUFACTURE IN GERMANY—We read the following statistics on German printing-press manufacture in the *Journal for the Art of Printing*: On the occasion of the jubilee of the great establishment of Messrs. Kottig and Bauer, at Oberzell, near Würzburg, a catalogue was issued, by this firm of those printing offices which were supplied with the first thousand of their steam presses. We find in this catalogue the firm of F. A. Brockhaus, at Leipzig, was supplied with 21 presses; of Decker, at Berlin, 20; A. H. Payne, at Leipzig, and the Imperial Printing-office at St. Petersburg each with 15; Cotta, at Stuttgart, and the Royal Mint at Madrid, each 14; M. du Mont-Schanberg, at Cologne, 12; Rivadeneyra, at Madrid, 11; Westermann, at Brunswick, 10; &c. Of those first thousand steam-presses, 719 remained in Germany, 119 were sent to Russia, 39 to Switzerland, 28 to France, 28 to Spain, 14 to Italy, 11 to Sweden, 10 to Austria, 9 to Denmark, 9 to Holland, 6 to Belgium, 5 to England, 3 to Brazil, 1 to Turkey, and 1 to the East Indies.

W. SPRECHLEY,
ENGINEER, MACHINIST.
AND LATHE MAKER,

No. 118, RAILWAY ARCH, VAUXHALL-WALK, S.

T. E. TAYLOR.

MODELLER OF NEW INVENTIONS,

LATHE, TOOL MAKER,

AND GENERAL MACHINIST,

110, FETTER-LANE, FLEET-STREET, LONDON, E.C.
Patterns made to drawing.

HOLLOWAY'S OINTMENT AND PILLS
SAFE AND SURE.—Day by day are cases of ulcers, wounds, sores, and contractions, and deformities cured by these well esteemed remedies, after all other known means have been tried in vain. Various veins, and all other descriptions of sores, ulcers, and bad leg, which seem to defy the best surgical skill succumb in a short time to the soothing, healing, and purifying properties of Holloway's Ointment and Pills. They operate both locally and constitutionally; they strengthen both capillaries and nerves, and regulate the circulation of the blood. The most valued testimonials are constantly received from persons whose diseases have been cured by these remedies, and which effected a complete cure, even after the constitution seemed thoroughly broken down.

Self-acting, Turning, and Screw-Cutting Lathes, OF THE FOLLOWING SIZES, For Sale, and Ready for Delivery:—

Height of Centres.
6½ Inches.

A TREATISE ON GAS-WORKS, and the Practice of Manufacturing and Distributing Coal Gas.
 By SAMUEL HUGHES, C.E.

Second edition, illustrated, revised by WILLIAM RICHARDS, C.E., price 2s.
 VIRTUE BROTHERS and Co., Amen Corner, London.

SCREW CUTTER'S GUIDE,

Price 1s. 6d., or stamps.

Containing 115 Pages and nearly 2,000 Trains of Wheels, all different threads and pitches.

Tables for Tap making for Engineers, 1/2 to 6 inches, Gas Taps 1/2 to 2 inches, Mr. Whitworth's thread and make.

A lithograph showing a new radius gear invented by the author of this work.

May be had at James Martin, 19, Wilson-street, New Cross-road, Deptford, Kent.

PLANS, ELEVATIONS, &c., Made, Copied, Traced, Reduced, or Enlarged, in the best manner, at moderate charges, by J. J. GREENE, 63, Upper Stamford-street, Blackfriars.

STANDARD GAUGES, Surface Plates, Straight Edges, Scales of Length, and other Instruments of Precision, of real accuracy and of all sizes.
 H. GARRIDE, 17 Coupland-street, Oxford-street, Manchester.

NOTICE.—Removing to No. 122, from 132, LONG ACRE, LONDON, W.C.—C. SUFFELL, Manufacturer of Improved Engineering, Surveying, and Drawing Instruments for Home or Foreign service. Every instrument of the finest quality at very reduced prices. Standard Measures of all Nations. Post-free Catalogues. Forwarded to all parts on remittance or London reference.

THE LENOIR GAS ENGINE.—A number of these useful and economical engines to be seen in actual work in town and country. Being free from all danger, they can be used where steam power is totally inadmissible. Exhibition, and every information supplied at 40, Cranbourne-street, Leicester-square, W.C.

SECOND-HAND CASES OF MATHEMATICAL INSTRUMENTS. Theodolites, Levels, Pentagraphs, Quadrants, Sextants, Universal Dials, Protractors, Circumferencers, Prismatic and Beani Compasses, Ivory and Boxwood Scales, Land Chains, &c., by Troughton and Simms, Elliott, Dolland, and others, at W.M. LAWLEY'S, 78, Farringdon-street, City. Photographic Cameras, Lenses, Magic Lanterns, Slides, Dissolving View Apparatus, Microscopes, Telescopes, Opera, Race, and Tourist's Glasses, by Voigtlander, Roe, Dallmeyer, and others. Instruments bought or exchanged. Catalogues forwarded on receipt of three stamps for each.

THE LONDON DRAWING ASSOCIATION for supplying Engineering, Mechanical, Architectural, and General Drawing, Designs, Maps, Plans, Tracings, Wood Engraving, Electrotyping, 7, Duke-street, Adelphi, London. Enclose stamp for prospectus.

TO INVENTORS.—GENERAL PATENT OFFICES.—L. de FONTAINEMOREAU, 4 South-street, Finsbury, London; 14, Rue de la Fidélité, Paris; 32, Rue des Minimes, Brussels. Provisional protection, 27; to complete patent, £30; French patent, £6 10s.; Belgium, £2 10s. Circular gratis on application.

"EXCELSIOR," "EXCELSIOR"
Family Sewing & Embroidering Machine

WITH ALL THE LATEST IMPROVEMENTS.

IS easy to operate, simple to learn, quiet in action, and not liable derangement. It will TUCK, HEM, FELL, GATHER, CORD, QUILT, BRAID, and sews from two ordinary reels, requires no re-winding, and the seam, if cut at every beh, will not rip. Price from £6 6s.

WHIGHT AND MANN, 143, HOLBORN BARS, LONDON.

MANUFACTORY—GIPPING WORKS, IPSWICH.

PRICE LISTS FREE.

Crickmer's Patent Plastic Metallic Packing.

FURTHER REDUCTION IN PRICE ON AND AFTER OCTOBER FIRST.
 PATENT WIRE GAUZE JOINT PACKING... 1s. 6d. per lb. INDIA-RUBBER CORE PACKING (HEMP)... 1s. 4d. per lb.
 CRICKMER'S PATENT PACKING... 2s. 3d. Do. Do. (COTTON)... 2s. 6d.
 This Packing takes less Tallow to lubricate it than any other, and being a Filable Metallic Surface requiring but little Pressure to Keep it Steam tight, there is a great saving in friction.
 PATENT TALLOW PUMPS AND LUBRICATORS.
 WELL STRETCHED LEATHER MILL BANDS, HOSE PIPES, FIRE BUCKETS, VALVES, WASHERS, &c., &c.
 CAUTION.—Engineers, Millowners, and others are Cautioned against Purchasing a Spurious Metallic Packing, purporting to be Crickmer's. THE GENUINE CAN ONLY BE OBTAINED FROM

PATENT HOLLOW STEAM PACKING.

THE great and peculiar advantages of this packing consist in its remaining perfectly elastic, and is so constructed and applied that the pressure of the steam itself makes the joint by entering the packing from the cylinder; thus the many objections to packing previously existing are effectually removed. Vulcanised India-rubber Sheet Washers, Valves, Springs, Hose, Glazed and Solid Tubing for Gas, Speaking Tubes, Diving Dresses, Gas Bags, Air-proof Goods, or any description of India-rubber articles made to order.

Price list or circular, with full description of packing, to be had of the only Manufacturers and Patentees of Hollow Steam Packing.

FOSTER and WILLIAMS, India-rubber Works, Cowper-street, City-road.

[PRICE ONE PENNY.]

PUMP FOR RAISING WATER FROM ANY DEPTH.*

THE raising of water from great depths is a problem difficult of solution if the water is to be elevated in a single jet. In very deep mines, such as coal mines, for example, where a depth is sometimes attained of from six hundred to one thousand eight hundred feet, the usual practice is to raise the water in stages; but this entails a considerable amount of complication. Mons. F. Prud'homme, of Paris has recently invented a pumping machine which raises the water in a single jet, without the intervention of separate stations, and which admits of the motive power being applied to any distance from the shaft. This apparatus consists of two parts only: the one, which is situate near the bottom of the shaft, or about 9 or 12 feet above the water, is the actual water elevating apparatus, and the other, which is situate outside, but as near as possible to the mouth of the shaft, although there is nevertheless no limit to the distance, is a force pump, which is placed by the side of the motor. These two apparatus, namely, the actual water elevator and the force pump, are in communication with each other by means of two pipes, which serve for the elevation of water and the transmission of the power. The elevator consists of a well-bored cylinder of cast iron or copper, closed at its two extremities by metal covers. It is divided into two separate and distinct parts by a solid transverse partition or central diaphragm, against which the reaction of the water exerts itself. Within this cylinder there are two solid pistons of equal diameters, fixed upon one common rod, working through a stuffing box in the centre of the diaphragm. Suitably disposed valves admit the water from the wells into the elevator, whilst other valves enable it to be expelled therefrom—the water being alternately drawn and forced by the action of the pistons. The reciprocating movement of the pistons of the elevating cylinder is derived from the force pump, although it may be situate several hundreds of yards from the elevator. The force pump consists of a solid piston, working in a cylinder or pump body, for the purpose of forcing the water therefrom, and it may be made either single or double acting, and placed either horizontally or vertically, as preferred.

The accompanying engraving represents a vertical section of one form of M. Prud'homme's force pump and elevator. This latter is placed say 12 feet above the water level in the well. The suction pipes, *h h'*, descend to the bottom of the well, and are perforated at their lower ends, as shown, to prevent foreign matter entering the pipes. *A* is a well-bored cylinder, closed at its longitudinal centre by a diaphragm, *a*, the centre of which is provided with a stuffing box, *a'*, through which works the rod, *b*, of the two pistons, *b b'*.

The ends of these cylinders communicate with the valve boxes, *c c'*, which contain the suction valves, *d d'*, and the outlet valves, *d' d'*. The openings, *e e'*, permit of the inlet and outlet of water to and from the cylinders. The pistons, *b b'*, are packed with cup leathers, or with metallic spring packing rings. The pipes, *r r'*, which may either be of cast or

wrought metal, and which should be put together with perfectly tight joints, connect the elevator with the force pump. They may rise vertically up the shaft, and may then be carried away horizontally any distance to the force pump, with which they communicate. Near to this pump the two pipes are connected together by the valve boxes, *l l'*, containing the twin valves, *f f'*. The body of the force pump must be well bored, and closed at each end by a cover provided with a stuffing box, *m*, through which works the rod, *p*, of the piston, *p*, packed in any suitable manner, and receiving a reciprocating motion from any prime mover.

o', where it will open the valve, *d'*, and enter the pipe, *r'*. The water in the end, *A*, of the cylinder contained between the piston, *b*, and the diaphragm, *a*, will also be forced into the pipe, *r'*, through the opening at *z*. The water will rise in this pipe up to the valve box, *l'*, and as the valve, *f'*, is open, a part of the water will enter the box, *o*, and finally flow away by the pipe, *o'*. Another portion of the water enters and fills the pump body, *m*, as fast as the piston, *p*, travels from right to left. In the meantime, the water forced out by the piston, *p*, fills the space between the diaphragm, *a*, and the piston *b'*, and a vacuum is formed between the piston, *b*, and the end of the cylinder, *A*, consequently the suction valve, *d*, rises, and the water from the well fills the valve box, *o*, and cylinder, *A*. The piston, *p*, having arrived at the end of its stroke from right to left, pauses for an instant, during which time the valves, *d* and *d'*, close again, and so soon as it returns from left to right it forces the water down the pipe, *r'*, thereby closing the valve, *f*, and opening the twin valve, *f'*. The valves, *d'* and *d*, now open, and the operation is repeated through the pipe, *r*.

In this apparatus it will be seen that there are three equal-sized pistons, the first of which transmits to the two others the movement which it receives directly from the motive power engine, by the intervention of the column of water contained in each of the vertical pipes, whatever may be the distance between the force pump and the elevator.

GALE'S PROTECTED GUN-POWDER.

Last week her Majesty and suite witnessed experiments with Gale's protected gunpowder in the Orangery at Windsor Castle. The experiments were conducted by Mr. Gale and Mr. Saunders, and throughout the proceedings her Majesty manifested the greatest interest.

A bowl of the protected gunpowder having been produced, a portion of it was separated in order to show the facility with which the gunpowder would be restored. The bowl, with the remainder of the protected powder, was then held by Mr. Gale, while a slow match was allowed to burn down into the powder. This produced no effect beyond lighting a few grains. Vesuvians were then thrown in, and finally Lord Bury's test was applied, which consists of exploding a small quantity of neat gunpowder in the midst of the protected powder. This part of the proceedings appeared to be especially interesting to her Majesty, who expressed her concern that Mr. Gale was holding the bowl too near to himself. It was, however, soon apparent that there was no danger. The Princess Beatrice and Prince Leopold, who were not present at

the commencement, joined the Queen at this moment, and Her Majesty was pleased to request that the experiments might be repeated.

The Queen asked Mr. Gale if he had recently discovered the invention; to which he replied that the explosion of the siege train at Inkerman was the first occasion on which his attention was seriously directed to the subject, and since that time he had been making various experiments in order to perfect the invention.

The experiments were brought to a close by placing a bag of protected gunpowder upon a fire,

The general action of the apparatus is as follows:—Supposing the piston, *p*, to occupy the position shown in the engraving, and moving from right to left, and the whole apparatus to be filled with water from top to bottom, and the pistons, *b b'*, and valves in their several positions indicated, the pressure of the piston, *p*, being exerted upon the water, will effect the closing of the valves, *f d'*, and the piston, *b'*, being forced from left to right, will carry with it the piston *B*: the water contained in the cylinder or chamber, *A'*, between the end cover and the piston, *b'*, will consequently be forced into the valve box,

* Translated for the *Practical Mechanics' Journal*, from *Le Genie Industriel*.

when it was gradually consumed without any approach to an explosion.

The Queen, on leaving, said, "Mr. Gale, I thank you. I have been much pleased and interested in the experiments. It is a wonderful invention, and ought to be made very, very useful."

Instead of using an ordinary sieve in the experiments before her Majesty, a new model separator was used, by means of which a more perfect and instantaneous separation of the gunpowder is made. This machine enables the gunpowder to be separated just as fast as it may be required for use in filling shells or making fireworks, or any similar operation in which danger now arises from the accumulation of explosive powder.

COPPER AND PHOSPHORUS.

By MR. F. A. ABEL.*

This paper was devoted to the description of a series of experiments made to ascertain if phosphorised copper would be more effectual as a material for the manufacture of cannon than the alloy now in general use. After referring to the different chemical compounds of copper and phosphorus known, Mr. Abel spoke of his experiments on phosphorised copper, with respect to its tensile strength. He found that an ingot of copper one inch in area broke under a strain of about 25,000 lbs., that of a similar ingot of gun metal required 32,000 lbs. Whilst copper combined with 5 per cent. of phosphorus required 38,389 lbs., and with 1.4 per cent. of phosphorus the strain that the ingot would bear was upwards of 47,000 lbs. Although these experiments showed the very superior tenacity of the phosphorised copper, yet there were practical difficulties which prevented the application of this compound to gunnery. In the course of the discussion which followed the reading of this paper, Mr. Abel stated that this phosphorised copper would not be at all suitable for telegraphic purposes, as the presence of phosphorus was most detrimental to the metal as a conductor of electricity.

After the paper, of which the above is an abstract, had been read, Mr. A. W. Wills made the following statement:—

So long ago as 1848 a patent was taken out by Mr. Alexander Parkes, of Birmingham, for the use of compounds of copper, zinc, nickel, and other metals, with phosphorus. The result of Mr. Parkes' experiments, more especially with respect to the copper compounds, had been so favourable as to enable him to claim for them many advantages—especially as regards the tenacity, hardness, and homogeneous character of the metal produced. This he proposed to apply to the manufacture of tubes, sheathing, cylinders for calico printers, and manifold other purposes.

Since the date above mentioned, Mr. Parkes has obtained other patents for modifications and improvements in his original process, and the manufacture of phosphorised copper, containing from $\frac{1}{2}$ to $\frac{3}{4}$ per cent. of phosphorus, is now successfully carried on at the extensive works of the Stephenson Tube Company, in Birmingham, with which the patentee is connected.

This metal is forged, drawn, and rolled both hot and cold, and its successful application to the manufacture of tubes, cylinders, sheets, and various other purposes, has established its claim to the possession of those qualities which are stated by Mr. Parkes to be its especial characteristics—viz., great hardness, homogeneity, smoothness and evenness of texture, and tenacity. Its employment for the manufacture of large cylinders for calico printing has been especially satisfactory, by reason of these qualities.

The successful issue of the whole manufacture appears, however, to depend upon the careful selection of materials, and upon certain niceties of manipulation, which are absolutely indispensable.

A PATENT CASE.

BARNETT AND ROUSSELL V. LEUCHARS. — In the Vice-Chancellor's Court the other day, Mr. Malins (with whom was Mr. Owen) moved *ex parte* for an injunction to restrain the defendant, William Leuchars, from selling in boxes bearing the plaintiffs' labels any serpents not manufactured or sold by the plaintiffs. The plaintiffs claimed to be the inventors of the new firework called "Pharaoh's Serpent," for which they had obtained a patent in France and its colonies, and provisional registration in this country under the Patent Law Amendment Act, 1852. The Vice-Chancellor said that the motion had better stand over, in order, that the defendant might be served with notice of it, and accordingly directed it to stand over.

* Read at the meeting of the British Association.

ANSWERS TO CORRESPONDENTS

POWER.—An American invention.

STEPHENSON.—Try Spon, publisher, Bucklersbury.

ARTHUR.—Any skilled mechanic in a smith's shop will give you the information; you can obtain the drillstock at any respectable tool shop.

PNEUMATIC.—Will find a belting made from cotton answer his purpose better than leather.

JACK ROBINSON.—It is a trade secret.

HARNSLEY.—You had better apply to a musical instrument manufacturer.

ED. PICKLES.—Received.

T. G.—Received, but unable to spare space.

FERGUS O'CONNOR.—Thanks for the hint.

VULPOS.—Call at 7, Bridge-court, Westminster, any evening after 8 o'clock where Mr. E. Korner, engineer, will give you every information on drilling small holes.

VENTILO.—Try 70, Guildford-street, Borough.

SHOEMAKER, BLEACHER, BUTCHER.—Answers to all the queries are to be found in any common household book.

WILLIAM COOPER.—Next week.

COUNTRY NOVICES.—Try 36, Sussex-street, Tottenham-court-road.

HENRY LEE.—If you had watched the correspondence carefully, you would have noticed several letters on the subject. See letter of Vincent C. Davis in present number.

TYRO.—None of our correspondents could (even if willing) give you the necessary instructions, without the aid of numerous engravings, these we cannot undertake the expense of.

W. H. H.—See the post office country directories.

J. R. P.—We will endeavour to obtain the information.

R. F. M.—On one side only, and as brief as possible.

JAMES PRICE.—The result of your experiment is curious, but there is nothing new in it.

DIAMOND.—It is an American patent, write to Munn and Co., 37, Park-row, New York City, United States.

DRILLING GLASS, T. R. M.—Search back numbers. The question has been answered very often.

B. B. W.—We do not think that it will answer our purpose to engrave the sketch. The difference in price was an error on the part of the printer.

J. C. (Glasgow).—Write to Spon, publisher, Bucklersbury, for a catalogue.

H. J. S.—Why not apply to some practical engineer in your immediate neighbourhood.

JOHN SMITH.—See the *Illustrated Builders' Journal*.

W. W. W.—Explain yourself more clearly.

D. McCANN.—Try the self regulating burner, Booth-street, Manchester.

J. N.—Perhaps in our next.

A. Z. C.—We have received your illustration, which being valueless beyond sulking your immediate requirements we cannot reproduce. The method shown is the proper one to adopt, and if greater effects are required you can either increase the surface of your condenser or the number of laminae of which it is composed; surface alone being the element with which you have to deal.

F. S.—Received, with many other communications on the same subject.

JOS. BERRY.—Joyce's prepared is the best, but it will always smoke until thoroughly ignited, and must be kept very dry.

NEMO.—You can obtain one to answer your purpose of George H. Smith, Market-lane, Ipswich.

REGINA.—Churchill, 11, New Burlington-street, will supply you with a correct one.

J. BARNETT, JUN.—In our next.

B. MANDAL.—Thanks for the hint. If possible we will find space for the articles.

JAMES MORRISON.—We regret that your communication arrived too late for insertion in the present number.

HELIX.—Will appear in our next.

ELTON.—Search the back numbers. Several very good directions have appeared for gluing and cementing leather.

EXPANSION.—In our next.

* * * We have to ask our correspondents to sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them by the thousand; the same with "Well-Wisher," &c. Several letters remain over till next week for answer.

Letters applying for information to be furnished by post cannot be attended to.

Correspondents are requested to keep copies of their drawings and manuscripts, as the Editor cannot undertake to return such as may be rejected.

IMPROVEMENTS IN LITHOGRAPHIC MACHINES.

Though not bearing much on engineering, still, as an instance of ingenuity, the lithographic printing machine of M. Huguet, exhibited at the Dublin Exhibition by Messrs. Hughes and Kimber, of Fetter-lane, London, claims attention. It is said to be capable of producing 7,000 impressions per day, which is more than twenty-three times the work that could be got out of the old machines, and there are besides suitable arrangements for varying the speed of working when necessary. The inking apparatus is self-acting, and in doing colour work the cylinder stops at each revolution to give time for adjusting the paper, which is a matter of the first importance.

INVISIBLE violet rays turn guaiacum to green, which the red rays restore.

The English Mechanic.

FRIDAY, NOVEMBER 24TH, 1865.

THE EXPLOSION AT NINE ELMS.

NOTWITHSTANDING the evidence given by Dr. Letheby at the inquest held on the bodies of the unfortunate men who met with their death in the recent catastrophe at Nine Elms, a large portion of the metropolitan public remain under the impression that immense districts are liable to be blown any day into smithereens by the explosion of any of the huge gasometers that "filthify" so many districts in and around London. Our excellent contemporary, the *Times*, which supplies a social, moral, and political code to so many, having been rather unfortunate in its scientific dabblings, has assisted in fostering this feeling of insecurity among the denizens of gas-worked neighbourhoods which, we are afraid, only the non-bursting of these immense reservoirs will in time allay. The *Times* asserted that one, at least, of the Nine Elms gasometers exploded—neither of them did any such thing. What, then, did explode? In the retort-house were three governors, or regulators, immersed in eight inches of water. Close adjoining were open smithy fires. So there were the gas and the means of explosion, other things in order for it. Some ignorant workmen—not those of the gas company—were employed in plastering this governor-house, and somehow or other, one or more of them had managed to tilt one of the governors on one side, and so allowed the gas to escape into the large room. There it became mixed with atmospheric air in such quantity as to render it explosive: the dreadful compound reached a light, the explosion took place, hurling masses of the strong building in

the direction of the gasometers, which, besides being thrown somewhat off their perpendicular by the sudden and severe concussion of air, were struck at the same moment by pieces of ruin projected by the explosion; thus holes were made in them, and hence what befel—but no explosion. One was converted into a huge gas burner, the gas within being burnt away in a huge column of fire, the gas in the other escaping through the vent into the atmosphere. It will be seen, then, that it was the *liberated* gas, mixed with atmospheric air, which exploded; and it may as easily be understood that it is next to impossible for a charged gasometer to explode. Air may get into a gasometer, but even then it would not explode. It would show itself at our burners, in a sputtering and a jumping, and occasionally a "going out," nothing more.

There can be no doubt, however, that gas-works in the heart of a city are in the wrong place. Emphatically, they have no business there. They are a nuisance, and, as such, should receive notice to quit. There are numerous localities away down the river where their filthy smell would annoy and injure no one, and where the expenses of the companies would be much decreased in one great item—coal carriage; for, away down the river, vessels could discharge into a jetty at the works, and save all cost of transhipment, as now, to bring the coals above bridge. The sums which each of their present immense and valuable sites would bring in would purchase enough land elsewhere for three works; and, altogether, the sooner they set about moving out of town the better for the inhabitants of the several localities, the public at large, and, doubtless, their own interests.

SORBY'S SPECTRUM MICROSCOPE.

THE superiority of the new form, as published by Mr. H. C. Sorby, consists in the employment of a compound direct vision prism over the eye-piece. The slit is fixed in the focus of the upper lens of the eye-piece, which is made achromatic, so that all parts of the spectrum may be distinctly seen at the same time. By using a binocular microscope, the inclined tube can be employed as a finder; and, on arranging so that a minute object is in the centre of the field, it will be directly in front of the slit fixed in the eye-piece of the other tube. On looking through this eye-piece, it is easy to see that the object is properly placed in front of the slit; and then, on placing the prism on the eye-piece, as if it were a Nichols's prism, the spectrum of the object can be seen to great advantage. This compound analyzing prism consists of two right angled prisms of flint glass, between which is a rectangular prism of crown glass, and at each end a crown glass prism of about 75°, all cemented together with Canada balsam. Arrangements are also made in the instrument, by means of a reflecting prism covering half the slit, so that the spectrum of a minute object placed on the stage may be compared with that of a larger object placed on a stage attached to the side of the eye-piece, and thus their difference or identity may be seen at a glance. It is thus easy to compare the spectra of minute crystals and of their solutions; to study the spectra of small coloured blow-pipe beads; and, in fact, accurately examine the nature of the light of any minute liquid or solid coloured substances. By using a parabolic reflector attached to the object glass, opaque bodies may be examined by reflected light; and, as a curious test-object, it may be mentioned that, by this means, a speck of blood on white paper, which would not weigh more than one-millionth of a grain, will show a perfectly characteristic spectrum.

RAILWAY STATION SIGNALS.

There is one question invariably asked when a night train draws up at a station—Where are we now? The painted board cannot be read in the darkness, but there is an immediate answer from the porter, but the worst of it is that answer, uttered with railway speed, or it may be in a provincial patois, is wholly unintelligible, and thus it happens nervous travellers get bewildered, and are frequently carried beyond the station where it was their intention to have alighted. On the Great Northern, the Great Western, the Brighton, the Metropolitan, and several other lines, they have, in order to remedy this evil, adopted a very simple arrangement devised by Mr. Wm. Grant, of Liverpool. It is this:—He has an iron frame to fit on to the top of the lamp, and from the sides of that frame he suspends a strip of stained glass lettered with the name of the station. The light from the lamp illuminates those letters, and renders them legible to any person.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents.]

ASTRONOMICAL TELESCOPES.

Sir,—As a tyro in astronomical science, I beg to tender my thanks to Mr. E. B. Wegg, for his admirable communication on telescopes in *THE ENGLISH MECHANIC* of Nov. 10th. A word as to cost, namely, £2 10s. No doubt cheap for a good instrument, but to a working man, at the present price of provisions a serious sum. New I have no doubt but that Mr. Wegg's ingenuity and practical knowledge would enable him to suggest how to procure a good telescope at a cheaper rate. I am aware that good lenses are indispensable to prevent refraction, &c., &c. This I believe to be the only difficulty. I have seen it stated, that lenses, for a very useful telescope, may be obtained, for about four shillings. I, for one, would feel exceedingly obliged for information how to accomplish this.

I may also observe that the thanks of the readers of *THE ENGLISH MECHANIC* are especially due to those gentlemen who so kindly answer queries inserted. **ATHELSTANE.**

FURNACE BARS.

Sir,—J. Manston not having responded to your invitation, and dissenting from T. Jackson, No. 28, Vol. 1. I forward herewith sketches of a bar designed by me upwards of 20 years since. Subjected to the action of various kinds of fuel, the results have proved highly satisfactory.

The diagrams represent top and side views, and an enlarged mid section in which A is the dead plate, the end next furnace being inclined for the bearing B of the fire bar to travel upon.

The difficulty generally experienced, arises, I think, from inattention to the laws of nature, i.e., non provision for expansion in length. That this plane it is worthy of consideration is evidenced by the fact of my having, during the recent erection of furnace work, again inserted a nest of town cast bars, after 3 years and five months constant service, all of them being perfect in shape and uninjured in the slightest degree, excepting where the surfaces are buried by the stoking irons in removal of slag.

F. G. MUEHLLAND.

STEAM BOILERS.

Sir,—Will you permit me to trespass on your time and space a little, the importance of the subject must be my apology. I consider it is necessary to have as clear views as possible on boiler constructions, and am willing to state my own views and experience. I am anxious also to have the views of others more experienced in this matter. In reference to A. Nelson, in your journal, Nov. 10, 1865, he says, "that I stated the hoops would only add strength to the weakest part." What I said was, the hoop would only add strength equal to its cross section at weakest part, that is, the part weakened by rivet holes.

The next fallacy your correspondent says is caused by his neglect to state the boiler designed was for an internally fired one, and in the case of flues the principle would be reversed, only the steel straps would be dispensed with. This is the only case in which hoops may be used to advantage. Flues of greater length than ten feet are generally hooped with T or angle iron to prevent collapse.

Again, your correspondent says I will perceive that the greater the number of hoops, the stronger the boiler, in some cases. Yes, but why not add to the thickness of plates in this case, it would cost no more for work. An increase of one 1/16th of an inch in thickness would increase the strength of a 6 feet boiler in its resistance to bursting pressure 75 lbs. square inch, while the increase of weight would only be 2 1/2 lbs. to the square foot of surface. As to defective welding, we never had a spoiled plate, and with proper care and method ordinary men may weld plates with certainty.

Plates, of course, may be rolled longer than required for boilers, and are done so at the risk of the makers, so that builders may always have good plates. As to rivetting being more safe and reliable, I beg to differ with A. Nelson. The punching of the holes near to the edge of the plate oftentimes seriously injures the plate, causing weak places in the boiler; in fact, so impressed with this are some engineers that they have their boilers drilled holes. **ASPIRANT.**

OUR SUBSCRIBERS' NOTES AND QUERIES.

MAGNETO-ELECTRIC MACHINE.—I shall feel obliged to E. Furze if he will let me know if the springs S, S, in his sketch of a magnetic machine, (in No. 27) are in metallic communication with T, T; also, if one thick perm magnet would do instead of a compound one? Perhaps he will give me the size of it in plain figures, as I do not understand decimals?—**JOHN DONNELLY.**

CANADA BALSAM.—Can you, Sir, or any of your readers inform me of a means of rendering Canada balsam which has set hard limpid and fit for use? I have tried heat, but I do not find it a satisfactory means?—**MICROS.**

TELESCOPE.—Can E. B. Wegg inform me how to make an ordinary telescope to magnify at a distance? Price about 12s. 6d.—**MAGNIFIER.**

CHEMIST'S FOLDING MACHINE.—Can any of your numerous readers and contributors inform me: 1st. If any mechanist has invented or patented a machine for charging, snipping, and folding small powders, such as chemists use for medicines? 2nd. If no such machine has been the subject of experiment, can you give the name of any mechanist within whose sphere of inventive labour such a machine might come?—**ARCHIMIDES.**

SOLDERING.—Can you, or one of your correspondents inform me how to solder metals together in the ordinary manner of soldering; and also, how to join fine work together by means of a chemical process; and the names of the instruments and chemicals used therein?—**W. H. S.**

ADDRESS WANTED.—If Joseph White will send his address to *THE ENGLISH MECHANIC*, I shall feel obliged?—**PNEUMATIC.**

STEAM QUADRANT.—Can any of your readers inform me how to find the diameter of the circle of quadrants in steam engines?—**INQUIRING JAMIE.**

TELESCOPE.—It is stated in Dr. Dick's "Solar System," part II, p. 57, that an achromatic telescope five feet long will bear a higher power than one of the common sort a hundred feet long. Perhaps some of your readers will tell me why this great difference is, and where I can obtain pure flint and plate glass for optical purposes?—**E. B. P.**

FLASH PAPER.—Can any of the readers of *THE ENGLISH MECHANIC* inform me where I can get flash paper in Birmingham?—**O. B.**

STEAMING AND BENDING ASH TIMBERS.—Can any of the readers of *THE ENGLISH MECHANIC* inform me of the best method of bending timber? I have tried several without succeeding to my liking. A SUBSCRIBER, Ashford.

PREPARING WOOD.—Can any one oblige me with the information, how I am to proceed in making pipes of such wood as apple tree or cherry tree fireproof, without spoiling the colour of the wood?—**T. E. R. G.**

SILVERING.—Can any of your readers inform me of the process of French dead silvering, such as used for dials of watches, &c.?—**W. MARTIN.**

MOTION.—Will any of your readers oblige me with a description of Watt's sun and planet motion?—**C. W., Peterboro.**

BEVIL COG WHEEL.—Will any one inform me how to make a pattern for a bevil cog-wheel and pinion; large wheel, 2ft. diameter; pinion, 8 inches; wheels to work at right angles with each other?—**G. S. C.**

LIGHT FOR MAGIC LANTERN.—Will any of your readers inform me how to procure a good and effective light, to show photographs in lieu of the lime light; where can a description of the "wavish light" be had?—**HARRY.**

REUMKORFF COIL.—Electra would greatly oblige by telling me: 1st. The size and weight of tinfil for a Reumkorf, such as he described. 2nd. If I could add a brass tube to moderate the shock? 3rd. If he knows where I can get the 42 wire, not covered? 4th. Will iron wire do for the second coil? 5th. The sort of carbon used for Bunsen's battery? 6th. If there must be the same number of inches of carbon of zinc exposed to action of the acid? By answering this you will oblige.—**REUMKORFF.**

PRESSURE ON STEAM VALVE.

Will any of your numerous correspondents inform me through your columns what will be the pressure per square inch of valve, when steam begins to blow off, levers loaded as above. And at what distance from centres of fulcrum must the weight W, be placed; that boiler may be loaded to 60lbs. per square inch.

A, B, is a safety valve lever, 13 1/2 inches over all, is uni-form, and weighs 2lbs. 14 oz.

F, is fulcrum, and is 2 inches from centre of valve spindle S.

W, is a lead weight fixed on lever, its centre is 9 1/2 inches from F, and weighs 33lbs.

V, is valve, and is 1 1/2 inches in diameter; valve and spindle weighs 1lb. 7 oz.

Lever is 1 5/16" broad (or deep), and 9 1/8" thick.

Centre of fulcrum is distant 18 1/8" from A.

I beg to thank Mr. J. Wheatley for his clear method of eccentric setting. Can he or others inform me how to set off a link in various positions (on paper), and why valve moves when gear is middled on turning engines by hand? My questions refer to link with rods attached to end.

J. M. S.

POLAR AXIS AND GRAVITY.

Sir,—In answer to your correspondent T. C., I may inform him that, according to the elaborate calculations of the Astronomer Royal, made in 1830, the polar axis of the earth measures 41,707,830 feet, and the equatorial diameter, 41,847,426 feet. Now, at the end of the year 1859, we received from General Schubert, of St. Petersburg, a re-determination, founded, however, upon relatively few data, of the figure of the earth (printed in the Memoirs of the Russian Imperial Academy of Science), in which he arrives at the curious result that our globe is not a solid of revolution, but that the figure of the equator is elliptical. He gives as the length of the polar axis 41,711,206 feet. The maximum

222:109

compression ———, and the minimum compression

1

The longitude of the equatorial major axis he

places at 41° 4'E, and that of the minor axis 131° 4' E. Upon attention being drawn to these remarkable conclusions, Captain A. R. Clarke, B.E., repeated the whole of General Schubert's calculations in a much more precise manner; using a greater number of observed latitudes, and bringing out the probable error of the elements. The results at which he arrived are these:—The ellipsoid which best represents his major axis in longitude 13° 58' 6" E. The greatest and least values of the meridian compression

1

are ——— in longitude 13° 58' 6" E, and ——— in

longitude 103° 58' 5" E. The length of the polar axis he finds to be 41,707,586 feet. The difference of the equatorial axes amounts to 10,616 feet, or, roughly, two miles. It is important to observe though, that Captain Clarke "conceives that it would be scarcely correct to say that we had proved the earth not to be a solid of revolution; to do that would require data which we are not in possession of at present, and several axes of longitude would be necessary."

In reply to C. E., without going into any theoretical detail, he may find the centre of gravity of any body, by suspending it by means of a thread from some point off its surface; and when at rest, marking as accurately as possible, the point at which the thread would come out did it pass straight through the body. Then the centre of gravity is somewhere in this line. Let him now suspend the body from some other point, and mark the vertical continuation of the thread, as before—the centre of gravity will also be somewhere in this new line. Then, inasmuch as it is in both lines, it must of necessity be in the point where they intersect.

A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.
November 14, 1865.

FRET SAW.

Sir,—In answer to J. W., I send a drawing and description of a fret saw which I have made, and had in use for three years. It is my own design, and I run it at a speed of from 300 to 500 cuts per minute, and the length of stroke of the saw is regulated, as will be seen in the drawing.

When circles are required to be cut, I adjust a clamp, with centre pin, to the saw table, and set it to the required radius.

A, disc, with adjustable crank pin for regulating the throw or length of cut.

B, saw table on a pivot O, and fixed by thumbscrew D.

E, saw held in screw jaws.

F, slide carrying the elbow lever, and fixed by a set screw behind.

G, G, grooved pulleys.

H, stretching band of crinoline steel, kept in tension by the slide F.

THOS. E. MERRITT.

UTILISING COTTON WASTE.

Sir,—An enquiry was made in a former number of your valuable periodical under the above heading. At that time I had not the opportunity of sending the desired information; but I now beg to say that cotton waste may, and can be utilised by steeping a short time (say 24 hours) in a warm alkaline solution, and thoroughly washing it through, when the alkaline solution will have united with the grease contained in the waste, forming a saponaceous compound, which may be further utilised by using the solution in lieu, or with a small addition of oil for lubricating purposes, or for making anti-friction grease for colliery or other purposes.

The waste is, after washing thoroughly, dried, and used again for similar purposes as heretofore, thus effecting a saving of upwards of 55 per cent.

S. DUTTON.

MULTUM IN PARVO.

Sir,—In reply to Arrow, Whitworth's scale for angular thread of the given diameter is as follows:—

Diameter of bolt	3"	7"	1"	5"	3"	7"	1"
	8	16	3	3	4	8	12
Threads to the inch	16	14	12	11	10	9	8

Angle of Thread 55°.

Hippo had better save his solutions and reduce them to their respective metals. With our present knowledge I think their application to plating purposes is out of the question. In electrical deposition we are obliged so far to be content with the argenteo and auro cyanides; if Hippo can cheaply convert his residues into either of these, he will achieve a success.

Chemists should try the cement made of bees-wax, resin, and Venetian red, several times described in your column, but what is infinitely better, is to have his spindle turned with a screw in the centre, and grip it by a nut and washer on each side. The washer may be easily and advantageously made of vulcanised India-rubber 1-16" thick. All other cement used should be sealing-wax dissolved in naphtha or methylated spirit.

Anselm Splain.—Silver will not serve as a substitute for platinum in contact breakers unless he wishes to spend ten times the cost of the platinum to produce—well, say, only failure. Gold and platinum are the only metals we know of that will serve the purpose, and the latter is the cheaper of the two, hence generally used. The spring should not be plated, but a small hole drilled through, and a piece of platinum wire rivetted therein, or otherwise a piece of platinum foil twisted on to the spring.

J. C. Wigg.—The permanent magnet is the steel one, and the temporary magnet the iron one in a magneto-electric machine. Steel ones are made by touch from other powerful magnets, or by insertion in a coil, through which a large volume of electricity is passed from a powerful battery, generally beyond the means of an amateur; the other is a simple core of the softest iron, that can be got wound with a large number of convolutions of very fine silk-covered wire, and only becomes magnetic by induction when passing the poles of the steel magnet.

Scientific.—Try gutta-percha. It takes plumbago as naturally as a child does the breast, and with a little care in manipulation, gives fine sharp results.

G. S. gives only a very incorrect method of finding the pressure per square inch on a boiler under a given strain, and not the strain a boiler would bear without rupture, as tested by the safety valve, which was the question put by T. G. Maugh. Try again, G. S., and despair not.

Last, but not least, Sparrow Hawk.—Glass tube for the helix would be awkward to obtain, and is unnecessary for the job. About thirty yards of thick cotton-covered wire wound in a short helix, and attached to from six to ten Grove's or Bunsen's cells coupled for quantity, should be passed several times backwards and forwards over the intended magnet, a soft iron armature being all the time kept in contact with the poles, whatever the shape of the magnet; then break contact with the battery, and remove the armature and coil.

T. H. B.—Nitrous acid reduced by the addition of a small quantity of water renders hard surfaces of cast-iron workable.

WM. TONKES.

VOLTAIC PROPULSION.

Sir,—In answer to your correspondent John Tawse, I would remark that his proposition has little novelty in it. Some years ago Professor Jacobi succeeded in propelling a boat containing twelve men by voltaic agency. Sir Humphry Davy also employed the same sort of battery which your correspondent suggests, but for a different purpose. To prevent corrosion in copper sheathing, he attached pieces of zinc to the copper, and the zinc, by undergoing corrosion instead of the copper, left the latter clean; but therein lay the fault, as the clean surface afforded such a good resting place, it was soon covered with marine shell-fish, &c., which is much worse than corrosion. If this was to take place on your correspondent's battery, the surface exposed would be much reduced, and the battery power would suffer in consequence.

Next comes the very important question. Would it be cheaper to use zinc instead of coal? For, as the coal is oxidised at the expense of the air, so is the zinc attached by the chlorine of the sea salt, and chemical action takes place in both. Now, the equivalent of carbon is 6, and that of zinc 32. Then, 6 atoms of carbon in combining with 8 of oxygen, set free as much force as 32 of zinc in combining with 35.5 of chlorine, so that more than five times the quantity of zinc is required, and consequently a much greater outlay is required. Liebig says, that the coal used in reducing zinc from its ores would set free more effective force by burning it under a boiler than would all the zinc in galvanic or other apparatus.

I have only one more objection, and then I have done. Your correspondent suggests that the metal plates should be insulated from the ship by means of gutta-percha sheets. Now, would the gutta-percha be strong enough to hold the rivets? for it is absolutely necessary that there be no metallic connection with the ship, or the gutta-percha would be of no use.

VINCENT C. DAVIS.

STONE CUTTING.

Sir,—In reply to J. L. query—there is a small work on "Masonry and Stone Cutting" in Weale's series, at 1s. There is also a machine patented that will do square yards of rough stones out of the quarry, and bring them to a true face in one day, and polish them if required. In fact, it will do for about 4s. what it requires by hand labour to charge 15s. for. I shall be happy to give any information respecting the above.

T. JACKSON.

THE SUN EXTINGUISHING FIRE.

Sir,—In answer to the question of F. Mason, November 10th, 1865, I beg to refer him to the *Imperial Magazine*, August, 1865.

The simple reason of the sun putting out fire when shining upon it appears to be that he extracts from the burning matter that oxygen, the supply of which is so essential to combustion.

But, to the more particular reason. I surely have no need to tell any of the readers of your magazine that fire will not burn without air. And, from the supply provided for this purpose, it is the oxygen separated by the burning materials from the atmospheric air which becomes decomposed by passing through them, that alone supports and prolongs combustion. If, however, as fast as these materials should, as it were, attempt to imbibe and appropriate oxygen, a counteractive power should deprive them of it, it is evident that combustion would slacken, and ultimately cease. Now, this theory appears to me to be demonstrated in the case before us. The sun shining upon the fire is the counteractive power. The rays of the sun have a strong tendency to draw off oxygen from certain bodies containing it.

Upon this principle some metallic oxides become decomposed, and lose their colour.

If a fire that is not burning very strongly, and is not supplied well with fuel strongly combustible, that is not open to a strong current of air, be left to have the sun shining powerfully upon it, the fire would soon go out, a result I have witnessed.

The sun is not likely to extinguish a large fire, such as a furnace, which is constantly supplied with fuel, and kept up by a blast.

But, with a parlour fire (to which the querist, I suppose, refers) long left without attendance, with the sun shining upon it through a window, and perhaps with the window and door both shut, the fire will soon die out.

A. GREGORY.

PLACING ECCENTRICS ON SHAFTS.

Sir,—Having seen the explanation of Mr. Wheatley about placing eccentrics on the shaft in No. 33 of your valuable paper, I would feel obliged if Mr. W. would give a simpler explanation of the way he marks them off to place them on the shaft in their proper position; by so doing he will much oblige.

I also beg leave to show the way I am accustomed to put them on. It is as follows:—

Find the two centres, A and B, through them draw the centre line D, C, with A for a centre, and A, B, for a radius. Describe the arc E, F, with B for a centre, and the lap + the lead for a radius; describe an arc, cutting E, F, in G; then from the centre A, draw the line A, H, through the point G. A, H, is the line to which the eccentric is set.

The foregoing explanation is written under the supposition that your enquirers know how to set their shafts before proceeding to set their pulleys.

A COMMON PL.

GRAVITY

Sir,—In answer to C. R., who wants to find the centre of gravity of any solid body. If he suspend a body which is bounded by two parallel planes from any two points within itself, successively marking, in each case a perpendicular line from the point of suspension, the centre of gravity will be found at the point of their intersection, which may easily be proved by suspending it in that point, when it will be found to keep any position it may be placed in. The same process would be applicable to any body, whatever its form, if we could pierce its dimensions by straight lines.

C. N.

FURNACE BARS.

Sir,—In reply to Mr. Pritchard's wish for further particulars regarding furnace bars, I beg to say that they are 3' 6" long, 4 1/2" deep at the middle, and the cross section in centre of bar, is 1 1/2" at the top, and tapers to 1 1/4" at the bottom. Weight 24 lbs. I have them in nine boilers 24 feet long, by 7 diameter. Of course, there are two lengths of bars in fire feet box, and I can at any time lift them with the naked hand, they being almost cold with the cold air impinging against them and passing through them. The air spaces betwixt the bars are 1/2". Of course, that depends upon the quality of coal used, I used slack.

THOS. JACKSON.

MAGNETISM.

Sir,—In answer to J. B., the transmission of an electric discharge through a steel bar under the influence of a magnet will produce permanent magnetism in the bar.

THOMAS HARR.

MISCELLANEOUS NOTES.

Sir,—T. Stodhard would find no advantage in using a condenser composed of alternate sheets of varnished paper and tinfoil over the Leyden jar. Certainly, it is quite possible to use a condenser to answer all the purposes of the Leyden jar, provided the sheets of tinfoil are properly insulated from each other, which is no easy task to do properly. The condenser should have one end or side connected with the ground (a damp bath will do), and the other brought in close proximity, without actual contact, to the prime conductor of your machine.

J. B.—Magnetism may be produced in steel either by coiling the article with a few turns of stout wire, and joining in circuit for a short time with a quantity battery, or by rubbing the steel article a short time across the pole of a natural or artificial magnet.

W. H. H.—Platinised silver plates are obtainable at Sykes, 4, Holly-place, Rockwell, S. The price of a plate the dimensions you name would be about 5s.

I have no doubt the author of the "Handbook of Practical Telegraphy," Mr. Culley, of the E. and I. T. Co. Bristol, can supply E. McGurk, or any of your correspondents with copies of his work. The price is 7s. 6d., with perhaps a trifle extra for postage.

F. B. may prepare his plaster casts for the electrotyping process by soaking them, or boiling them in bees wax; next, polish the surface to be electrotyped with plumbago, or blacklead, and attach to your bath in the usual way.

EDWIN FUZZE.

CENTRE OF GRAVITY.

Sir,—In reply to C. R., No. 33, respecting centre of gravity. Centre of gravity is that point (in a body) which, if supported, the body will remain at rest in any position whatever. Or, it is that point about which there are equal equilibria.

To find the centre of gravity: Suspend the body by two different points, find the lines of direction in each case, and the point where these lines intersect is called the centre of gravity. A piece of wood, for instance.

The piece of wood A, B, C, D, has been suspended at the point C, and the line of direction B, C, has been drawn, the diagram represents it as being suspended at the point A, the line of direction A, D, is shown; therefore, the point E, where the two lines of direction (B, C, and A, D,) intersect is the centre of gravity of the piece of wood A, B, C, D. The method of suspending the body is simply this: Take a piercer, and round its blade place a piece of cord or thread, to the end of which is attached a small weight (such as P in the diagram), insert the piercer's blade in one of the points of suspension, and the string will mark, or coincide with, the line of direction.

In answer to F. Mason, No. 33, respecting the power of solar rays to extinguish the heat of a fire:—

It is a well known fact that when a person's clothes are on fire, a blanket wrapped closely round the burning clothes more speedily extinguishes the fire than any other article. The same principle applies in the present case, the rays of white light being a non-conductor of heat surrounds the fire, and forms a coating or covering round the fire, which, in time, completely extinguishes it.

DAVID SLOAN THOMSON.

DANIELL'S BATTERY.

Sir,—In reply to Wm. Hoskin, respecting Daniell's battery, does he think a battery using sulphuric acid would last constant a very long time? I do not think it would last a week, and the zincs would very soon spoil, making it very expensive.

The railway telegraphs use only water, and last a long time. Some of their batteries are not attended to for six months, but I do not understand their exact construction.

Can any reader give me the exact details of the construction of a Daniell's round form battery?

ALFRED CROFTS.

VEHICLE FOR COLOUR.

Sir,—Not having seen any reply to Give and Take in No. 20, I offer the following:—

One ounce of borax, 2 ounces of shellac, 1 pint of water. Boil a few minutes, stir with a piece of wood; or 1 ounce of liquid ammonia, 2 ounces shellac, 1 pint of water. Give and Take may add more or less shellac, or use any colour he can obtain at the chemist's.

Will any one tell me what thickness wood, say oak, can be cut with the circular saw, driven by foot power?

A. LES.

ENGINEER'S SCREWS.

Sir,—Arrow will find a very good table for tap making, from 1/2 in. to 1 in. in diameter—it will show how to make a full set—in the "Screw Cutter's Guide," advertised in THE ENGLISH MECHANIC.

JAMES MARTIN.

TELESCOPY.

Sir,—I have to thank your correspondents for answering my enquiry about the barometer; but, for the benefit of those of your readers who study telescope, I may mention that, on application to Messrs. Simpkin, Marshall, and Co., for the work on that subject that Old Charlie recommends, I was informed that it is out of print, and has been so for some time.

TORRICELLI.

WINDOW MACHINERY.

Sir,—Snip can purchase a machine for his purpose much better, and cheaper than he can make one. Messrs. Bennett and Son, of St. Paul's, Birmingham, make these machines.

ALFRED NICHOLAS.

THANKS.

Sir,—Allow me to express my obligations to Mr. McGurk for his attention to all my queries.

As he gives his address, I will not occupy any more of your valuable space, but will communicate with him privately by post if I require any further information of him.

AMATEUR MECHANIC.

INSTITUTION OF MECHANICAL ENGINEERS.

The general meeting of the members was held on the evening of the 2nd instant, in the Lecture Theatre of the Midland Institute, Birmingham, Henry Maudsley Esq., Vice-President in the chair.

The secretary (Mr. W. F. Marshall) having read the minutes of the previous meeting, a large number of new members were elected, and the officers of the Institution were nominated by the meeting for the next annual election.

The first paper read was "On an Improved Safety Valve for Steam Engine Boilers," by Mr. William Naylor, of London, the object of which is to prevent the steam, while blowing off through the safety valve, from rising in pressure beyond the limit to which the valve is adjusted. The valve is loaded by a spring acting through a lever, one end of the lever bearing upon the valve, while the other end is bent down out of the straight line to such an extent that the point of attachment of the spring, instead of being in the same straight line with the bearing points of the valve and the centre pin, is at an angle of fifty-five degrees to that line; and, therefore, when the valve is lifted by the steam pressure the depression of the tail end of the lever causes the effective leverage at which the spring acts to be shortened simultaneously with the extension of the spring. Hence the increased pressure of the spring, consequent upon its extension by the lifting of the valve when blowing off, may be entirely counteracted by the shortening of the leverage at which it acts; and in practice the bent form of the tail end of the lever is so adjusted that, when the valve lifts by the steam blowing off, the load upon the valve is actually diminished, notwithstanding the increase of pressure of the spring. With the ordinary safety valves, on the contrary, loaded with levers and spring balances, the whole increased pressure of the spring is thrown on the valve lifting, and the increase in the boiler pressure sometimes reaches a very serious amount. Even a dead weight upon the valve, as in stationary and marine boilers, allows of considerable increase of boiler pressure when the steam is blowing off. It has, therefore, become necessary to devise some arrangement whereby the effective pressure of the spring upon the valve may be diminished when the steam is blowing off strongly; and this is effectually accomplished in the improved valve by the bent lever upon which the spring acts. The improved valve is thereby enabled to lift to the full extent required for affording complete freedom to the steam blowing off, without under any circumstances allowing the pressure of the steam in the boiler to increase more than 5 per cent. beyond the limit at which the valve is set to blow off. At the same time the valve closes again after blowing off strongly; without allowing any sensible fall in the boiler pressure below that limit. The improved valve is in use on a number of locomotive boilers, and it is accordingly found that a single valve of only 2 in. diameter gives the full area for discharge of the greatest generation of steam that is possible; while with the two large ordinary valves that are generally used of 4 in. or even 5 in. diameter, the pressure rises very seriously when blowing off strongly. Specimens of the valve of different makes were exhibited.

PHOTOGRAPHY.

Mr. Warren De la Rue's lunar photographs are not only interesting as pictures of our satellite, but are found to be of great importance in a scientific point of view, for an eminent astronomer has declared that, in rectifying our knowledge of the moon, more has been accomplished by these photographs in one hour than by forty years' observation of occultations. This is a promising corroboration of what has been

already remarked concerning photography, that it will become of essential importance to astronomical science. For example, the moon's libration is a phenomenon of which the observation has long overtaxed the patience and ingenuity of observers; but with photography it will be at once comparatively easy and exceedingly accurate. Henceforth, a photographic department will have to form part of every good observatory.

Messrs. E. and H. T. Anthony, of New York, call our attention to a novelty in photographic paper, which, if it fulfil the promised conditions, will be a great acquisition to the art. It is stated to have a pure dead white insoluble surface. At present we have seen nothing of it; but as an interesting announcement we give the description with which Messrs. Anthony have favoured us. It is styled "Brinckenoff's Procelain Surface Photographic Paper," and the following advantages are claimed for it:—1. The insolubility of its surface, which allows it to be passed through all the solutions necessary to the production of the photographic image without raising the fibre, which in other papers causes the sinking of the impression into the tissue, rendering it flat and indistinct, and requiring the use of some vehicle, such as gum, gelatine, or varnish, to bring it to the surface. 2. Its extreme purity of tone, whiteness of the lights, depth of the shadows, and delicacy of the half-tints, heretofore unattained on any plain paper, and its possessing all the strength of detail found in albumen paper, without the unpleasant gloss and hardness so much deprecated in all large pictures where albumen is used. 3. The surface, which is a pure dead white, resembling finely-ground porcelain, causes the image to stand out from the back-ground with a stereoscopic effect which contrasts strongly with those made on surfaces that are porous and absorb the impression into the body of the paper. 4. The facility of manipulation, requiring only the ordinary salting solution, ammonia nitrate of silver (30 grains to the oz. of water) brushed over the surface, alkaline gold toning and fresh hypo fixing, to produce the finest effect obtained by the most complicated formulas. 5. The great advantage of allowing the artists to colour the photographs either in oil or water-colour, in less than half the time required on ordinary papers, without the use of any other preparation than that contained in the paper on which the image is made. The surface, though insoluble, is sufficiently absorbent to take in the colour without any loss in force or detail. 6. The susceptibility of a high polish under pressure if it is desired for small pictures that require colouring, such as vignette cards—usually so difficult to produce a good effect upon, owing to the non-absorbent quality of the albumen. These are some of the distinguishing characteristics of the 'Procelain Surface Paper.' Other and no less important advantages will be readily seen in the use, such as their freedom from discolouration while drying in the dark room, the permanency of the impression, the short time required in washing, for the reason that the paper, being submerged, the pores are all filled up with the material used in its preparation; hence the sulphide of silver cannot find any lodgment in the tissue of the paper, and fading is prevented, &c., &c." These are the claims, we understand, made by the inventor, and should possibly be taken with a grain of salt, an inventor being very apt to over-estimate the charms of his bantling.

MODIFICATION OF THE LENOIR GAS ENGINE.

A very valuable improvement in the Lenoir gas-engine has been effected by M. Hugon, of Paris. Hitherto, the explosion of the mixture of coal-gas and air employed in these engines has been effected by means of a voltaic spark, but M. Hugon effects it by a contrivance which is at once somewhat cheaper and much more regular in its working. To the slide or other valves regulating the admission of gas and air into the cylinder he attaches little burners, supplied with gas under pressure, and he so arranges that the flame from these burners shall explode the mixture in the cylinder at the proper time. These little jets are blown out by the explosion, but are afterwards relighted by an outer jet, which is kept constantly burning. This simple improvement seems likely to considerably diminish the uncertainty and irregularity which have hitherto characterised the action of the gas-engine.

Tin wire, the thirteenth of an inch in thickness, sustains 347 lb., a lead wire but 28 lb.

The first pendulum clock was made in 1641, for St. Paul's, Covent-garden.

THE VELOCIPEDE.

WE have before us some half-dozen sets of drawings, from our amateur friends, of this useful vehicle, which seem to come more into vogue the greater the distance working men have to travel between their homes and their "jobs," carrying their tools with them in many cases. As we could not use every one's plans we have selected a few here and a few there. Of the double vehicle we give the only views come to hand. It will be evident that a high rate of velocity can be got out of one of these, constructed for the two men who are always to use it. There is a remarkable sameness in the descriptions appended to each set of drawings—in fact, in giving one we give nearly all; so no offence can be found with us on that score. The figures will be explained in the matter to follow:—

Fig. 1 is a side elevation, and Fig. 2 an end elevation of the double vehicle. A is the framing, B, B

centre, and is 9in. from back end of carriage. In making up the frame must be made red hot, and a recess formed $\frac{1}{2}$ in. wide by 5-16th in. deep to allow it to come fair to underside of seat. The distance from centre of axle to underside of seat is 9in., the wood of the seat is 1 inch thick; so, with 2in. of cushion the driver is raised a foot over the centre of the wheels, and the centre of the seat is over that of the wheels. The seat, it may be remarked, is usually made a foot in depth, and 14in. wide. A $\frac{3}{4}$ th rail is run round the seat, and fixed at the back, to give stiffness. The back of the seat should be well dovetailed to the sides, and the seat is also secured to the frame B, B by clips C, C, in U form. A hole is drilled through the clip sides and frame for riveting. The clip ends are bent out at right angles for the screws. The rib R R is fastened to the seat by screws, two on each side the frame. The forward end of the frame is to be well fitted into the hole d, (Fig. 16). A hole, H, is drilled through the brass

plate, F, is fastened by clips *c c*. One end of the treadle bar is turned up, and the other formed into a double joint, as shown. The bent-up end has a brass fitted, similar to the axle brass, though smaller; the joint at the other end is for the lower end of the suspension link. The bearing ends of the treadle bar are shown more distinctly in Figs. 9 and 10; the joint at the end of these bars is shown at Figs. 11 and 12, and the pin at Fig. 13. This pin, as shown, is kept in position by a split end. One of the before-mentioned suspension links is shown at Fig. 14. The length from centre of pinholes is 14 $\frac{1}{2}$ in. The plain part of the suspension link is 14 $\frac{1}{2}$ in. diameter, and the eyes—which should be well "trued"—are $\frac{3}{4}$ in. by 7-16in. thick. The hole through the brass socket S, Fig. 3 for the spindle *s, s*, (Fig. 15) of the guiding wheel is $\frac{3}{4}$ in. diameter. In the same figure will be seen two bosses, *b b*, one on each side the socket into which are screwed the two arms, T, T, carrying the links which swing on the ends of the arms (which are

the driving wheels, worked by a cranked axle C, having cranks *c₁, c₂, c₃, c₄*. The cranks *c₁, c₂* are worked by treadles D₁, D₂, and connecting rods *d₁, d₂*; and the cranks *c₃, c₄* are worked by levers E₁, E₂, E₃, E₄, and connecting rods *e₁, e₂*. F F are india-rubber springs; G, G, are seats; H, H, steering apparatus; I, lamp; J, J, bars supporting the rod; K, on which the treadles, D₁, D₂, turn.

Fig. 3 is a side elevation of a single vehicle, constructed of steel in all except seats and wheels—which, however, may be made of iron. The framing, B, B, is 4ft 8in. long, $\frac{3}{4}$ in. deep, and $\frac{3}{4}$ in. thick. This, the backbone of the machine, is let into a brass socket, S, which carries the spindle of the guiding wheel.

One rib is fixed under the seat, to which it acts as a support, and this rib (shown in Fig. 4) is $\frac{1}{2}$ in. wide, 5-16ths in. thick, laid down with its wide side to the seat. The rib centre is coincident with the wheel

and iron, and a bolt inserted (shown at f, Fig. 17.)

In Fig. 4 the dimensions of the driving axle are also given. The crank throw is 6in., and the distance, as seen, from seat centre to centre of bearings as *b b* is 13 $\frac{1}{2}$ in. The diameter of the axle is 1 $\frac{1}{2}$ in., the bearings being turned down to $\frac{3}{4}$ in., their length being 1 $\frac{1}{2}$ in. between the collars. The bearings at *h h* are for treadle hooks, the length of wheel is 1in., and diameter $\frac{3}{4}$ in. The ends of the ribs (Figs. 5 and 6) are formed to hold the brasses in which revolve the axle bearings. The brasses are fitted into the U shaped straps, and retained in position by a flange as in Fig. 7. A steel key, K (Figs. 5 and 6), is passed through the strap ends to keep the axle from leaving the brasses, and a pin (*p*) is inserted in the key end to keep it from drawing back. The straps noted are $\frac{1}{2}$ in. by 1 $\frac{1}{2}$ in. The treadle (Fig. 8) is $\frac{3}{4}$ in. wide, and $\frac{1}{2}$ in. thick; and to each side of the treadle bars a foot

turned down to $\frac{3}{4}$ in. diameter). A collar *c* behind the centre; a washer, *w*, on the end of the arm holds the link in position, and a pin across the point of the arm holds the washer. The diameter of the driving wheels should not be less than 3 feet. It is only necessary to fix one wheel on the axle for driving, the other revolving freely to allow of facility in turning corners. The guiding wheel and fork with its dimensions are shown in Fig. 18. This wheel is 20in. diameter, the boss is bushed with brass, and the hole is parallel. The fork is made of iron $\frac{3}{4}$ in. wide and $\frac{1}{2}$ in. thick; the spindle has a diameter of $\frac{3}{4}$ in. A collar, *c*, is formed on the spindle to allow the socket S, (Fig. 3) to rest thereon, as described. A loose washer, *w*, is provided with a pin, to confine the socket in an upward direction. In conclusion we have to return our thanks to the

rious correspondents who have obliged us, nothing doubting but that the correspondents who sought the information will be obliged to us for so doing.

NEW BULLET MACHINE.

In the United States department of the Dublin Exhibition, Mr. Ward has on view an ingeniously contrived bullet machine. The frame consists of two hollow square sides, connected by end and feet cross pieces, between which is the gear wheel, driving pinion, fly, and compound band-wheel, and on each side piece is an arch for suspending the reels that contain the lead wire from which the bullets are made. The main shaft passes across the entire machine, with two bearings on either side piece. Between these bearings are two cams that propel the punch and die cam frame, which are guided by fixed cross pieces, and during the formation of a bullet the dies are rigidly closed. The lead wire is supplied from the reels by a self-adjusting feed, carried back by the retrograde movement of the punch bar; and by the aid of a spiral spring keeping the feed-tube lever against the set pin; the lead wire is brought into contact with an adjustable stop in the jaws of a vertical compressing forceps, which are then rigidly closed, and the horizontal cutting forceps brought into requisition, which severs the lead wire while under transverse compression. After this the vertical forceps are opened by the retrograde movement of the punch bar, when the severed piece of lead drops into a receiver in front of the dies, and is forced by the punch bar, on its forward movement, into the dies, when the bullet is formed; immediately afterwards a retrograde movement is given to the die cam frame separating the dies, leaving the newly formed bullet on the point of the punch, from which it is released by its base coming in contact with the blank receiver on the retrograde movement of the punch. There is also an arrangement for causing the lead wire from which the bullets are made to pass through packed oil-tubes immediately previous to being used. There is one remarkable difference between this invention and the machine used at Woolwich—namely, that Mr. Ward's machine, unlike the one referred to, takes up in the beginning only so much lead as is necessary to make the bullet, the Woolwich machine having to get rid of a portion of the quantity of lead first taken up.

HOLTZAPFFEL'S ELLIPTICAL CUTTING FRAME.—By Ash.

The elliptical cutting frame, invented by Captain Ash, is employed in the lathe for ornamenting turned surfaces with elliptical figures, after the same general method that the eccentric cutting frame is employed for producing circular figures on similar surfaces—viz., the object to be ornamented is fixed on the lathe mandril, and motion is given to the tool by the elliptical cutting frame, which is fitted to the receptacle of the sliding rest; or the two movements may be combined at pleasure. An almost infinite variety of patterns of a highly ornamental character will, therefore, be produced by the elliptical movement alone. In addition to which, the instrument is adapted to produce epicycloidal patterns of four loops, similar to those produced in the geometric chuck; these looped figures may likewise be made in all proportions, and be placed in any positions. From these comprehensive powers of the elliptical cutting frame, it results that any desired arrangements may be produced of circles, ellipses, right lines, or four-looped figures—the instrument is, therefore, a most desirable addition to all lathes for ornamental turning, and, if required, its powers may be still further increased by the addition of other epicycloidal patterns, or by combining its movements with those of the eccentric chuck or other apparatus for ornamental turning.

The elliptical movement of the tool is produced, as in the geometric pen and in Ibbetson's geometric chuck, by the combination of two circular movements in opposite directions, the one of which travels at double the angular velocity of the other. This is effected by the train of wheels seen in the front of the instrument, which are so arranged that the eccentric frame carrying the tool A makes two revolutions to the right, while the radial flange B makes one to the left; and the proportions of the ellipses described by the tool depend upon the relative degrees of eccentricity given to A and B. Thus, when A and B are both placed central, the tool has no eccentricity, and merely produces a dot. When eccentricity is given to A alone, the tool describes a circle, the radius of which will depend upon the movement

given to the screw of the eccentric frame, under the guidance of the micrometer head C, which has ten divisions. Supposing the eccentricity to be equal to four turns of the screw, or forty divisions of the micrometer head, and that it is desired to convert the circle into a straight line, the flange B is also moved forty divisions, by means of the adjusting screw D, upon which a winch handle is temporarily fitted. Any series of ellipses between the straight line and the circle may be described by reducing the eccentricity of the radial flange B. Thus, if it be shifted five divisions between each figure, a series of seven ellipses will be produced, gradually advancing from the right line to the circle. Any other number of divisions may be adopted in the same manner—the instrument being so adjusted that equal numbers of divisions on B and C always produce the straight line. Series of concentric ellipses are produced by adjusting both A and B.

The radial action of the flange B, however, has the effect of placing the ellipses oblique to each other, instead of parallel, and this requires some compensation to be introduced. Captain Ash compensated the obliquity by shifting the division plate of the lathe a proportionate quantity. Subsequently the spindle was extended through the stem of the instrument, and a graduated disc, fixed on the end of the spindle, was employed for the compensation, but which is more conveniently and accurately effected by means of the worm wheel and tangent screw movement, suggested by H. Perigal, Esq., F.R.A.S. The tangent screw E is moved by a winch handle, and has a micrometer so arranged that the movement indicated by one division exactly compensates the obliquity produced by moving the flange B one division; and, therefore, to ensure the parallelism of the ellipses, it is only necessary to employ the same number of divisions on B and E. The tangent screw movement may also be employed to give any angular position to the ellipses that may be required. Thus, the worm wheel having 150 teeth, $37\frac{1}{2}$ turns of the tangent screw will place any of the figures at right angles to their former positions. Four-looped figures are produced by changing the train of wheels. For ellipses, the train consists of a fixed wheel of forty-eight teeth, leading into one of twenty-four, to which is attached a thirty-six wheel, leading into another thirty-six wheel fixed to the axis carrying the eccentric frame A. For four-looped figures, the relative velocity of the eccentric frame is doubled by employing wheels of forty-eight and twenty-four teeth, instead of the pair of thirty-six wheels. The adjustment of four-looped figures for eccentricity and position, is effected in the same general manner as the adjustment of elliptical figures.

CORNISH STAMPING MILLS.

Mr. Hilary Bauerman's descriptive catalogue of the various models in the Museum of Practical Geology is an excellent book, and is a valuable work of reference to the traveller through that very interesting building. In the work is described, among others, the stamp-clamp at the Carn Brea Mill, and that at the Par Consols, Cornwall. The stamping mill in the machine employed for reducing minerals to a state of division sufficiently fine to allow of the classification of their component parts by the action of water. It consists essentially of a series of vertical beams, called stamps. Shod with masses of wrought and cast-iron, which are lifted by cams fixed on the circumference of a rotating barrel, and allowed to fall on the fragment of ore beneath them. The powder, or coarse sand, the product, is removed by a stream of water passing through the coffer, the discharge taking place either through a perforated metal plate, a grating of bars, or by the swell of the water over a thin-edged board or weir—the last being termed a "flasher." In the Carn Brea mine stamp, the stamp heads are 72 in number, divided into two lines of 6 each; the steam-engine is placed between them, and drives the cam barrels by a pair of short shafts, each carrying a fly-wheel, which are coupled together by the pin of the driving cranks. The stamps work in sets of three, divided from each other by upright pillars, to which are attached thick oaken planks, forming a closed box or coffer to a height of about 20 inches from the ground. The ores to be stamped are introduced, together with a stream of water, through a square hole in the hinder wall of the coffer, whilst the finely-divided material is, as noted, carried out by the stream through perforated metal plates on the front wall. The stamp bed is a mass of white cast-iron, of an irregular prismatic form, furnished with a tapered projecting tongue at its upper end, which is sunk into a corresponding socket at the lower end of a vertical timber beam, called a lifter, and is secured in place by two narrow wrought iron bands. The lifter moves vertically between two pairs of parallel guides, which are attached to transverse bars, uniting the dividing pillars of the sets together, a wooden tongue projecting at right angles from it about midway between the guides receives the action of the rotating cam shaft. Each head is lifted five times in every revolution of the engine. The cams are made of cast-iron, shaped to an involute curve, having wedge tails, by which they are keyed into their sockets on the cam barrels; the latter are hollow, cast-iron, cylinders, with flanged ends, united together by screw bolts; the journals are attached by covering plates, similar to those of the large Cornish water-wheels. A simple disengaging clutch is introduced in the middle of each line, dividing it into two parts, each of 18 heads. The ends nearest to the engine are connected with the driving shaft by ratchet couplings, an arrangement which allows the engine to be run independently of the stamps, if necessary; its chief object, however, is to prevent the possibility of the cam barrels being turned in the wrong direction, if, by mistake, the engine should be reversed by the driver at starting. The bed on which the stamp works is formed of a hard quartzose stone, stamped in a dry state to a depth of 18 inches between longitudinal walls of masonry. The ores, broken into lumps of about two cubic inches volume, are brought in wagons along a railway raised 10 feet above the ground running parallel to the whole line, and a short distance behind it, and are received in large hoppers with inclined bottoms leading into the backs of the stamp coffers. The descent of the lumps is effected partly by their own weight, partly by the general shaking set up by the falling stamps on the framing, and partly by the action of the water, which is introduced near the outlet of the hopper. In the year 1857 the Carn Brea stamp included 96 heads, divided into sets of four, each one weighing 660 pounds, and striking $44\frac{1}{2}$ blows per minute, with a fall of 9 inches, the driving shaft making $8\frac{1}{2}$ revolutions in the same time. The motive power is furnished by a single-acting high pressure condensing steam-engine, with an unequal-armed beam; the steam piston is 32 inches in diameter, making a stroke of 9 feet; the radius of the crank is only 4 feet. The two fly-wheels are each 20 feet in diameter. Each head will stamp about 200 tons of ore per annum, or about 13 cwt. daily (24 hours); the amount of water consumed is about two gallons per head per minute. The discharging grates are plates of copper, perforated with holes of 1-20th or 1-40th inch diameter. The weight of stamps employed in other tin mines in Cornwall varies from $3\frac{1}{2}$ to $7\frac{1}{2}$ cwt., the lighter ones being usually employed where water is

the motive power. The height of the lifts is from 9 to 10½ inches.

In the stamps at Par Consols the lifters are made of rectangular balks of Norway fir, with wrought-iron tongues and guides; the latter are formed by two pairs of triangular prisms of equilateral section, one edge being turned outwards, they rub against planks of soft wood attached to the cross bars of the framing. The shorter sides of the coffer, as well as the front, are provided with discharging grates, formed of perforated iron plates; each of these rest against an iron backing, lining the aperture on the inner side of the box, and is kept in position by a wrought iron pressure frame, secured by a cross bar resting on two arms projecting from the outer side of the coffer. The front grate is of extra large size, measuring 23½ inches in length by 7 inches in height. The weight of the stamp head complete is 5½ cwt.; the lift is 10 inches, the number of strokes per minute is 50. A double cylinder engine, on Woolf's principle, of about 50 horse-power (effective), is employed; it moves 76 heads, of which 68 are worked on tin, and the others on copper ores; 20 are "flashers," and the remainder stamps through grates. The ore stamped by each head is 265 tons per annum, or about 27 per cent. more than the yield per head at Carn Brea. The sandy mud passing out through the grates is received in a rectangular channel, called a strip; there are two of these for every set of four heads, which are in use alternately, one being cleared out while the other is filling; they are of the following dimensions:—12 feet long, 14 inches broad, 12 inches deep, with a forward slope of one in 72, or 2 inches in the length. The reputed density of the material collected is 1·3; this would give a weight of about half a ton for the contents of one strip when filled, or 14 cubic feet at 80 pounds. The filling takes place in twelve hours, during which time the four heads in the set will have worked through two tons of the ore; the sand deposited on the strip amounts, therefore, to about 17½ per cent. of the weight of the ore originally treated. The finer materials retained in suspension by the water are collected in large basins, called slime pits.

THE ENGINEER'S SLIDE RULE.*

There is, perhaps, no instrument in existence so generally used, and yet so little understood by those who use it, as the Slide Rule, the generality of mechanics viewing it simply as a "stick of inches," while the more valuable properties it possesses are utterly ignored by them.

This, to a great extent, may be accounted for by that inertia of the mind, which continually cries *qui bono?* if any attempt is made to move it from the groove in which it has habitually worked, but still more by the fact that nearly all that has yet been written upon the subject, professing to describe the instrument, is written in a style well suited to the accomplished mathematician who does not require it, but unsuited to the ordinary mechanic, being in fact a combination of technical terms without definition, and a multitude of rules without a *why* or *wherefore*, and thence it is that most who make a fair start towards mastering its difficulties soon sink into apathy, and rarely, if ever, renew the attempt.

If therefore in attempting to bring this instrument within the range of all I may occasionally appear too prolix to your higher class readers, I hope they will skip over those parts as bad readers do with hard words, remembering that there was a period even in their experience when it would have been difficult for them to explain why twice two equalled four.

The engineer's slide rule as arranged by Mr. Routledge contains on one side 24 inches, sub-divided for general use, and scales from $\frac{1}{16}$ to 1.

On the other side, with which only I have now to deal, there are four "lines of numbers" marked respectively A, B, C, D, all equal in length, and the first three, A, B, C, divided exactly alike and numbered 1, 2, 3, 4, 5, 6, 7, 8, 9.—1, 2, 3, 4, 5, 6, 7, 8, 9, 10. While the line D is numbered from 1 to 10 only, each division being double the length of the corresponding one on A, B, or C.

These lines are technically termed "logarithmic," and as the term is not generally understood by mechanics, I will briefly define it. The logarithm of a number is the exponent or index of that power of a given number which is equal to the former number, thus, for instance, $100=10^2$. Here the exponent of the given number 10 is 2, signifying that 10 is to be squared, and that it will then be equal to 100; hence 2 is the logarithm of 100 when 10 is the base of the logarithmic system, and that is the one generally used for various reasons.

Now if we take a series of the powers of 10, say—

1. 2. 3. 4. 5. 6.
10, 100, 1,000, 10,000, 100,000, 1,000,000 &c.

and place over each the index of its power (or its logarithm), we find that the series forms a geometrical progression—being obtained by a continual multiplication of the base 10 into itself, while the indices or logarithms form an arithmetical series of which 1 is the common difference.

On examining these two series a very remarkable property which they possess is observed, for if we add together any two of the indices and look under their sum we shall find the product of the two numbers which these indices represent.

For instance, take 2 and 3, the sum of which=5, under 5 we find 100,000, which is just equal to 100 and $1,000$ multiplied together, and the same result would obtain however far the series were carried, hence if we had a table of these powers of ten and all the intermediate numbers, and also the logarithms of these numbers, by simply adding any two logarithms and finding the number indicated by their sum, we should at once have the product of those numbers represented by the sum of the logarithms which we added, thus performing multiplication by addition. Again, if we subtract one logarithm from another, the remainder will be the index of a number which would result from division of the numbers indicated by the logarithms chosen; thus $6-4=2$ and $1,000,000$ divided by $10,000$ is equal to 100 , the number of which the index is 2.

Thanks to the labours of those who have gone before us levelling our track till we have comparatively "a royal road to learning," we now possess such tables as those referred to, and those "who go down into the sea in big ships," as well as those who make the "big ships" to go down in, can amply testify to their value, and such a table, limited in extent, but almost universal in its application is engraved on those four lines A, B, C, D, of the slide rule.

In order to form this table, the space from 1 to 10 is divided into 1,000 equal parts, of which 301 is set off from 1 to 2; 477 from 1 to 3; 602 from 1 to 4 &c., 301, 477 and 602 being respectively the logarithm of the natural numbers 2, 3, and 4. Each division is then sub-divided proportionally into 1-10ths, representing the decimal parts between the natural numbers. Looking again at the table above given of the powers of 10 and their logarithms, it will be seen that the logarithm of 10 is 1; and therefore the logarithms of all numbers below 10 must be decimals, thus, for instance, the logarithm of 2 is .301, and such is the nature of these logarithms that if we multiply or divide 2 by 10, or any of its powers, this decimal index (.301) is unaltered, save that an additional number is used in combination with it, such number being termed its characteristic, because it points out the precise power of 10 by which the 2 has been multiplied or divided.

Thus:—

Log. 2=0.301.	Log. 9=0.951.
" 20=1.301.	" 100=2.001.
" 300=2.301.	" 1,000=3.001.
" 2,000=3.301.	" 10,000=4.001, &c.

it being observed that when division takes place, the index has a dash placed over it, signifying that it is negative.

Applying these observations to the logarithmic lines on our rule we see the reason why the numbers there marked are considered as arbitrary or that any value may be placed upon them, provided that it be a multiple of such number by 10; thus the first 1 may be called 1·10, 100, or 10^1 , 1000, 11,000, &c., but in all cases the other numbers must take their value from that assigned in any particular operation to this first number.

In reading off or assigning the value of the results obtained by any manipulation, the index or power of 10 resulting from such operation must be borne in mind, since that will determine whether the number formed consists of integers, decimals, or both combined.

It is in this, which may be termed the "numeration" of instrumental arithmetic that the great difficulty of the learner lies, but I shall endeavour to simplify it as much as possible a little further on.

I have already shown that if we add together the logarithms of two numbers the sum gives the logarithm of the product of these numbers, and on this is founded the method of multiplication by the slide rule. When the logarithmic line was first placed on scales by Mr. Gunter it consisted of a single line, such as A on the present rule, and the operations were performed by taking the distances with compasses and adding or subtracting accordingly, as multiplication or division had to be per-

formed; thus, to multiply 8 by 4, we should extend the compasses from 1 to 4, and then placing one leg upon 8, the other would extend to 32. In like manner, if 96 had to be divided by 12, we take in the space from 1 to 12, and measuring back (subtracting) the number indicated would be 8.

This however was inconvenient, necessitating the use of two instruments, and was superseded by the genius of a Mr. Everard, who gave us the slide and groove as we now have it.

This, however, required a slight modification in the mode of working which is expressed in the general rule, viz:—

"Set the 1 on B to the multiplier on A, and against the multiplicand on B is the product on A."

Taking the example above given, we place 4 on A against 1 on B, and opposite 8 on B we find 32 on A.

So again in division, if 96 be divided by 12: we set 12 on A to 1 on B, and against 96 on A, we find 8 on B, being simply the reverse operation to that of multiplication, we subtract the logarithmic distance instead of adding it, and since these two rules form the basis of all calculations, however complicated they may appear, if they are once thoroughly mastered very little difficulty will ever oppose the career of the instrumental arithmetician.

(To be continued.)

THE SOHO WORKS, BOLTON-LE-MOORS. From the Engineer.

(Continued from page 92.)

To an unprofessional visitor everything is new and astonishing in a large mechanical workshop; but an engineer rather directs his gaze to more or less exceptional things. We must thus confess that we were previously unaware that such large pistons as 3ft. in diameter, and even more, could be made with the narrow piston rings first introduced into this country by Mr. Ramsbottom, of Crewe. The large horizontal blowing cylinders for Mr. Bessemer's converters are made with such pistons. We notice that the cast-iron rings of the ordinary V-piston have additional elasticity given them by hollowing out the inside with a V-groove, and by then drilling a series of holes round the circumference, which are afterwards opened with as many radial saw cuts. Messrs. Hick and Son, with Messrs. Galloway, of Manchester, are, we believe, the sole English engine makers licensed by Mr. Bessemer to manufacture his blowing engines, converters, hydraulic cranes, and the general apparatus used in his process. A number of Bessemer converters and other work of the kind were thus being made here, amongst which we noticed a small one, 4ft. 4in. in diameter, ordered by Mr. Ramsbottom, of Crewe, for carrying out experiments in the conversion of Bessemer steel. A good deal of work is here turned out for the Royal Arsenal, amongst which we observed some small surface condensers, on Spencer's principle, intended for stationary engines. Close by was being fitted up an engine upon Corliss' patent. With a somewhat complicated appearance, and an arrangement of gearing which could not be made clear without diagrams, we feel, as the result of our examination, no doubt that the success of these engines in America and some parts of Germany, where fuel is much dearer than with ourselves, has been well deserved. At these works was, we believe, first introduced some years ago, a very simple and efficient mode of strengthening the internal flues of boilers. T-iron rings are used, on which the plates are rivetted thus  a space being left between them for access in caulking, while the T-iron ring itself can be caulked in the usual way. We noticed a great number of flues made upon this principle; and the rings of plate were in addition welded together at the longitudinal joint, thus forming almost as strong a flue against collapse as could possibly be made. These works are noted for the use of a particular mixture of very hard brass. As an instance of what can be done in this way, we may state that, while in Preston a short time ago, we paid a visit to Messrs. Horrocks' large mill, which has been at work for nearly seventy years. Exactly twenty-five years ago, the late Mr. Benjamin Hick erected there a pair of very handsomely-designed beam engines, each of 100-horse power nominal, but together now working up to some 670 indicated horse-power. The cylinders are 45in. in diameter, with an eight-foot stroke, and were probably designed to work at about ten revolutions per minute, though now driven at double the speed. We were informed by the managers of the mill that these engines had been working without the least repairs for the last quarter of a century, and that the crank brasses had during that long period only worn down one-sixteenth of an inch.

* Contributed by Mr. W. Tonkes.

Amongst other comparative novelties in engineering to be seen here is an engine upon Mr. E. E. Allen's principle—a plan now very generally known to the engineering public, more especially in the shape of a portable engine. It has been indicated up to 60 horse-power, and is now driving two fans, and mixing machines, and other work for the large foundry of the establishment.

An interesting peculiarity of the Soho Works is the number of novel schemes for various purposes in stationary work, which are being tried or are being actually manufactured to meet a demand. Experiments of this kind may very often be directly unremunerative, but they are attended with indirect advantages of various kinds, amongst which may be reckoned the acquirement of a reputation for keeping abreast with the times, as well as a resulting general stimulus to the powers of invention of the draughtsmen and foremen in the works. Amongst the novel apparatuses of this category is a very ingenious hydraulic press for packing cotton, the invention of Mr. Luthy, a gentleman in the employ of the firm.

To those who have studied the history of the hydraulic press it is well known that the late Mr. Hick gave it the finishing touch after its leaving Braham's hands, having, as can be proved by irrefragable evidence, first invented and adopted the self-expanding collar as at present used. Large numbers of hydraulic presses, and at one time, the largest presses made in the trade, have been turned out at these works. As Mr. Luthy's very ingenious press is the one recommended by the firm for packing cotton—for machines of which kind there is now a large demand in that now reviving trade—we may briefly describe it again, as it is mainly designed to economise time and labour in pressing cotton, as also to render the press itself more portable. At the same time, it must be remarked, that only a set of diagrams would do justice to its arrangements. The first portion of the stroke in packing the cotton bale—during which, as in packing hay, there is necessarily but little pressure required—is rapidly performed by means of a ram of small diameter, into the cylinder of which the water is, of course, quickly pumped. This small ram is either placed inside or outside the large cylinder. When its work is done, and more pressure and less speed is required, the force pump is made to act on the large ram, which completes the stroke. An ingenious self-acting apparatus is used for alternately admitting the supply to the rams. It consists of a suction valve, for the supply of the large cylinder during the first part of the stroke, and of a valve weighted according to the pressure of the pumps or accumulator, besides the ordinary arrangements for letting off the water. It opens and gives the pressure to the large cylinder, when the small ram meets with a resistance equal to the pressure on its useful area. There are several other noteworthy points about Mr. Luthy's press.

Mr. Hick has also tried that curious scheme for raising steam—Grimaldi's rotary boiler. The inventor is an Italian, Dr. Grimaldi, and a specimen of his boiler was to be seen in the Italian Department of the 1862 Exhibition. Such is the progress of science and the changes of time. In the last century Italy sent us Grimaldi the clown famous for his summersaults; in this century she exports a Grimaldi rotating boiler. We understand that the apparatus which is now showing worked very fairly, but that neither an increased evaporation nor a diminished deposit showed itself as a set-off for the necessarily additional complication and expense. We also doubt whether the plan is even valid as a patent, for a similar scheme is to be found described in a very old back volume of our contemporary the *Scientific American*. A very different mechanical invention is the arrangement, the invention of Mr. R. Harwood, a gentleman in the employ of Messrs. Hick and Son, adopted by the firm for easily regulating the speed of turbines and water-wheels. Applied to a turbine the clow for regulating the inlet of the water is connected to a piston. This piston is worked by means of water, let in on either side by a valve, which valve is opened or shut by a ball governor, driven by the prime mover. The motion of the clow is thus directly regulated by means of the governor, which has only to overcome the resistance of the valve itself. In the sectional elevation *a* is the throttle valve of the turbine, connected by means of the lever *b* and link *c* to the piston rod *d*, on which is the piston *e*. This piston moves inside the cylinder *f*, being actuated by the pressure of water admitted through an ordinary slide valve, which valve is itself connected, through the valve rod *g* and lever *h*, with the governor *j*. When, therefore, the turbine is running at the proper speed the valve occupies a central position, covering the ports, thereby

preventing ingress or egress of water to the cylinder, and the throttle valve *a* is thus kept stationary. But should the speed be increased the governor balls fly out, and lowering the valve at end of the rod *g*, allow the pressure of water to come on the top side of piston, which moves downwards and closes the throttle valve until the right speed is attained, when the valve again occupies a central position, and locks the throttle valve as before. If, on the other hand, the speed becomes reduced, the valve at the end of the rod *g* is raised, the water pressure is brought to bear on the underside of the piston, and the throttle valve is proportionately closed until the right speed be again attained. This simple plan has been successfully in use for some time.

Amongst the inventions of Mr. Bell, the principal millwright of these works, is a simple lubricating apparatus largely made here. In the course of our visit we saw many hundreds of the above very ingenious form of self-lubricating bearing for mill shafting, and as many thousands are in use in Lancashire mills. A goodly number of different self-lubricating apparatus for shafting have been tried at various periods, but lubrication by hand is still in very general use. We remember a noted case where, in some large works in Manchester, each bearing was provided with an apparatus, worked by gearing and causing the oil to flow drop by drop from a glass cup.

(To be continued.)

BRONZING.

Sir,—In answer to H. T. B., I send the following recipe:—

Dissolve copper filings in aquafortis; when the copper has impregnated the acid pour off the solution, and put into it some pieces of iron, or iron filings; the effect of this will be to sink the powder to the bottom of the acid; pour off the liquor, and wash the powder in successive quantities of fresh water. When the powder is dry, it is to be rubbed on the figure with a soft cloth, or piece of leather; but observe that previously to the application of the bronze powder, a dark blackish sort of green is first to be laid on the figure; and if you wish the powder to adhere stronger, mix it with gum water. Lay it like paint, with a camel's hair brush, or previously trace the parts to be bronzed with gold size, and when nearly dry rub the powder over it.

Gold size is prepared from a pound of linseed oil with four ounces of gum animi; the latter is reduced to powder and gradually added to the oil while being heated in a flask, stirring it after every addition until the whole is dissolved; the mixture is boiled until a small quantity, when taken out, is somewhat thicker than tar, and the whole is strained through a coarse cloth. When used, it must be ground with as much vermilion as will render it opaque, and at the same time be diluted with oil of turpentine, so as to make it work freely with the pencil. An important ingredient in bronzing is gold powder, which is prepared in the following manner:—Leaf gold is ground with virgin honey on a stone, until the leaves are broken up and minutely divided. The mixture is then removed from the stone by a spatula, and stirred up in a basin of water, whereby the honey is melted and the gold set free; the basin is then left undisturbed until the gold subsides; the water is then poured off, and fresh quantities added until the honey is entirely washed away; after which the gold is collected on filtering paper, and dried for use.

If H. T. B. intend bronzing plaster figures, the following instructions may be of use to him:—Lay the figure over with isinglass size, until it holds out, or without any part of its surface becoming dry; then, with a brush, such as is termed by painters a sash-tool go over the whole, taking care to remove, while it is yet soft, any or the sizes that may lodge on the delicate parts of the figure. When it is dry take a little very thin oil gold size, and with as much as just damps the brush, go over the figure with it, allowing no more to remain than causes it to shine. Set it aside in a dry place free from smoke, and in eight-and-forty hours the figure is prepared to receive the bronze.

After having touched over the whole figure with the bronze powder, let it stand another day, and then with a soft dry brush rub off all the loose powder, particularly from the points, or more prominent parts of the figure. It will then resemble the metal intended, and possess the quality of resisting the weather.

R. F. W.

The tower at Rouen, in which the unfortunate Joan of Arc was imprisoned, is about to be restored according to plans by Professor Morin.

PROPELLING BOATS.

By means of an invention which has been patented by Mr. John Macintosh, of North Bank, Regent's-park, and Mr. A. H. Thurgar, of Surrey-place, Norwich, the necessity of looking back to observe the direction of a boat is obviated. This invention consists, firstly, in using two rowlocks or fulcrums on each side of the boat; secondly, in using jointed oars, the joints of which work between the said rowlocks or fulcrums, so that in pulling the handles of the oars towards the stern of the boat the blades of the oars will be forced through the water in the same direction as the handles, thereby obviating the necessity of the rower or rowers turning round; thirdly, the oars are each made in two parts, and in connecting them together each flange of the joints or hinges is fastened securely to each part of the oar, and united together by a centre pin, thereby forming a hinge. The rowlocks are attached to the gunwale of the boat, the outer one projecting (about six inches) from the inner one, and the joint of the oar or scull working at about the centre between the two rowlocks. The novelty of the invention thus lies in the use of two rowlocks to the oar instead of one, as in the old system. The oar being jointed, the inner rowlock serves as the fulcrum to the handle of the oar, the joint of the oar between the rowlocks as the point of opposition, and the outer rowlock as the fulcrum to the blade of the oar. It follows, therefore, that, as the rower pushes the handle of the oar forwards, the joint between the two rowlocks is thrown back, causing the blade of the oar to move forwards in the same direction with the handle, and consequently as the rower pulls the handle back, the blade striking the water returns in the same direction, propelling the boat forwards.

GENERAL NOTES.

TO CLEAN TARNISHED PLATE.—Silver or plate objects may be very conveniently cleaned, if tarnished, by dipping them, when they are small, into a moderately concentrated solution of cyanide of potassium, and when they are large, by brushing the solution over the tarnished portions, then washing well with distilled water, and afterwards drying with a linen cloth.

USEFUL TO PAINTERS.—The effect of light on the aniline colours, and their decomposition which takes place with ordinary varnishes, may be avoided by first dissolving them in alcohol, saturating the solution with gum dammar, filtering, pouring the filtrate into a solution of common salt, and drying; then incorporating with an oil varnish that is free from lead.

MAGNESIUM.—Recent experiments have shown that magnesium is an excellent conductor of electricity. This, with the little tendency it has to oxidise in the atmosphere, recommends it strongly as a substitute for the wire used at present in telegraphic lines: and its general adoption depends, no doubt, on its economic production, in which direction advances are made every day.

SOLUBLE GLASS IN BUTTER.—It is too true that butter is sometimes adulterated with soluble glass—a compound of silicic acid and potash. But the adulteration may be discovered by agitating a portion of the butter with ether, which dissolves the fatty matters, leaving the rest behind. It may be proved that this residue is soluble glass by pouring hydrochloric acid over it, heating, calcining the residue, and when it has cooled, acting upon it again with hydrochloric acid, which dissolves the alkali and leaves the silicic acid, the chief constituent of the soluble glass, behind.

TO FIREPROOF TEXTILE FABRICS.—A very excellent method of rendering textile fabrics fireproof without injuring their colour, whatever it may be, consists in dipping them in a solution containing thirty-five per cent. gum, thirty-five per cent. starch, and thirty per cent. of the compound which is obtained by dissolving superphosphate of lime, decomposing the salt by excess of ammonia, filtering, purifying with animal charcoal, concentrating by evaporation, decomposing with five per cent. silicic acid, evaporating to a crystalline mass, and then drying and pulverising.

YANKEE NOTIONS.—Our American friends are not behind in saving themselves trouble where they can. A few weeks since we described a pea-shelling machine; we now learn that they think it too tedious to chop up cold meat for hashing, and therefore a machine has been provided to do it by power. All that is necessary is to put the meat in a case containing a number of revolving knives; then turn a handle and the hash is made. All the meat is minced before it issues from the further end, where there is a spout to allow it to discharge. This, however, appears to be nothing more than a coarse kind of hand sausage machine long used in England.

LEAD WORKS IN AMERICA.—At the last census there were in the United States 28 lead-smelting establishments, employing 203 hands. The capital invested is 286,922 dols.; cost of raw material, 938,561 dols.; cost of labour, 58,260 dols.; annual value of products (ending June 1), 1,094,122; tons of pig-lead 10,395.

OBTAINING MOTIVE POWER.—An invention, the special object of which is to enable the heat produced by combustion to be utilised in the production of motive power through a greater range of temperature than is now done, in order that a larger proportion of the heat may be converted into mechanical effect, has been provisionally specified by Mr. M. P. Boulton, of Tew Park, Oxon. He states that heat may be imparted to the fluid by injecting into the vessel some substance in a state of fusion—metals, or salts of metals—the steam being used in various ways as that produced in the usual method is employed.

A NEW ALLOY.—Gilding is much practised in the ornamentation of buildings in modern times, but silver is little used for a similar purpose, because of its liability to tarnish when attacked by sulphide of hydrogen, thus limiting the decorator to the use of gold. M. Ch. Lange, of Paris, has invented a new alloy, equalling silver in brilliancy when used in the decoration of buildings, and said to have a base unalterable by atmospheric influences. He calls this alloy metalline, and it may be used for any imaginable purpose, such as coating statues in terra cotta, porcelain, biscuit ware, or any article which it is desired to silver.

PREVENTING ACCIDENTS IN MINE SHAFTS.—Mr. C. H. Taylor, of Birmingham, proposes to provide a toothed rack along the entire length of the guide-rods, toothed wheels being placed upon the cage to take into them; a block with corresponding teeth is suspended to the chain or rope in such a manner that while the rope is tight the wheels run freely, but in the event of breakage the block falls, and locking the wheels prevents the further descent of the cage.

TIMBER OF AUSTRALIA.—The *Inquirer* (Western Australia) says:—"An engagement has been entered into to deliver on board ship at Freemantle 600 loads of mahogany sleepers for an Indian railway at £3. 13s. 6d. per load. Millions of acres in the colony produce a timber which no other part of the world produces, and it is virtually indestructible by white ant and sea worm. Our colony is the only part of the world where this commodity exists, and where the supply is virtually inexhaustible."

The Dublin Exhibition closed last week with considerable ceremony and in the presence of a brilliant assemblage. The Duke of Leinster occupied the chair, and speeches were made by the Lord Mayor, the Archbishop of Dublin, Mr. Whiteside, Sir Robert Kane, and other persons.

HOW THE SEED CONTAINS THE TREE.

In the single-flowering cherry-tree, which gives the most distinct illustration of the fact, the pistil is formed from two carpellary leaves, which have become succulent and united together so as to form a component pistil with a single cavity containing one young seed. Reflecting on this, in connexion with the nature of buds and leaves and minute examination of the germ bearing the plumule and radical of a bean, it appeared clear that a germ of vegetable life exists in every joint of a plant. To try this, a joint of common mint appeared the best for experiment. This was placed in water, having been cut off as close as consistent with leaving the joint uninjured at the lower end. A bud soon appeared on one side, which quickly formed itself into another joint, from which a root grew out, whilst the original bud continued to progress, and seemed disposed to show the characters of a monocotyledonous germination, assuming a green tinge at the extremity. However, a second joint formed, and another root was thrown out from it. A decided upward growth now continued, and buds and leaves were formed at all the joints subsequently developed. This would prove that every joint in a plant is a life-knot or collet, from which, under favourable circumstances, a plant or tree may be developed should it be separated from the original stem, and that it corresponds with the radical plate of a bulb, the crown of herbaceous plants, and germ from which the plumule and radical are developed in seed.

A CONVENIENT DISINFECTANT.—The most convenient, and I believe the most effective disinfectant, is chloric ether. It should be burned in a glass spirit-lamp, which is liable to the same mishaps as other spirit-lamps. Any place of the size of an ordinary room, that can be closed, can be completely deodorised and disinfected by five minutes' use of one of these lamps.—*Scientific American*.

PATENT LIST.

(From the Commissioners of Patents' Journal.)
LIST OF SPECIFICATIONS, &c. PUBLISHED DURING THE WEEK ENDING 11TH NOVEMBER, 1865.

1. Constructing public houses, &c., W. Muir—1s.
2. Stamping machines, T. A. Macanlay—1s. 6d.
3. Testing asphalt and other mineral phosphates, M. R. Levermore—4d.
4. Jacket for metallic vessels, E. Bevan and A. Fleming—8d.
5. Manufacture of oxygen gas, J. F. Parker and J. Tanner—4d.
6. Lubricating the journals of wagons, J. Smith jun. and J. Williams—10d.
7. Manufacture of carpets and hearth rugs, J. Spencer and N. Broomhead—4d.
8. Smoothing or finishing paper, J. R. Crompton—4d.
9. Treating pitch obtained by distilling palm oil, R. Irvine—4d.
10. Mounting photographic and other pictures, F. Gye—4d.
11. Lift and force pumps, M. Benson—10d.
12. Glass for use in photography, W. G. Helsby—4d.
13. Sewing machines, G. Macartney—4d.
14. Fermentators, &c., H. Lloyd—10d.
15. Manufacturing paper, L. D'Auberville—1s.
16. Surgical pneumatic apparatus, T. J. Aston—8d.
17. Ladies' belts, L. Goldberg—4d.
18. Combined drill, vice, and apparatus for lifting, G. Holgson and J. Pitt—8d.
19. Packing and lubricant for pistons, E. Keirby—8d.
20. Measuring water and other liquids, W. Payton—4d.
21. Mules for spinning, J. Knowles and J. Banks—1s. 3d.
22. Electro-magnets, W. Clark—4d.
23. Fan blowers, W. Agar—10d.
24. Spring mattresses, D. Verichio—4d.
25. Paper board, J. F. Jones—4d.
26. Cleansing and polishing knives, G. Kent—8d.
27. Stoppers for bottles, jars, and fire-arms, N. Thompson—10d.
28. Checking receipts of railway clerks, W. H. Roy—4d.
29. Propelling vessels, W. Watson—10d.
30. Signalling on railway trains, G. Pickworth—4d.
31. Advertising, G. H. Davies and J. W. Jones—4d.
32. Washing and mangling machines, J. W. Dransford—8d.
33. Generating steam and heat, J. M. Kirby—4d.
34. Ploughs, J. Skelton—4d.
35. Locomotive engines and carriage springs, J. E. Wilson—4d.
36. Sewing machines, A. V. Newton—1s. 3d.
37. Constructing and cleaning tubular boilers, J. C. Amos and W. Anderson—1s. 3d.
38. Hulling grain, G. A. Buchholz—2s. 4d.
39. Preparing and keeping aerated beverages, T. Pickford—4d.
40. Artificial fuel, J. K. Vignolet—8d.
41. Hydrocarbon vapour lamps, J. C. Bayley and D. Campbell—4d.
42. Boiling grain sugar in vacuo, J. Lebaudy—4d.
43. Looms, J. A. Oastree—4d.
44. Machinery for ginning cotton, B. Dobson, W. Slater, and E. Halliwell—4d.
45. Weaving ornamental fabrics, J. Crow and J. Macanlay—4d.
46. Smelting zinc ore, A. Reynolds—4d.
47. Preserving eggs, W. C. Thurgar—4d.
48. Locomotive engines, C. De Bierge—4d.
49. Shaping boot and shoe heels, G. Haseltine—4d.
50. Artificial fuel, J. K. Vignolet—8d.
51. Furnaces, ash-pits, and flues, J. Robertson—4d.
52. Railway signals, E. Tyler—2s. 6d.
53. Reciprocating watches, G. Raymond—10d.
54. Wrought-iron ordnance, H. Ames—4d.
55. Motive power, and signalling on railway trains, G. B. Galloway—4d.
56. Photographs and photographic transparencies, B. W. Bentley and W. H. Bailey—8d.
57. Vacuum pans, E. Beanes and C. W. Finzel—1s. 3d.
58. Metallic bedsteads and other articles, J. Atkins—4d.
59. Manufacture of iron and steel, W. Baker—4d.
60. Brooch fastening, J. J. Blackman—8d.
61. Hair brushes, &c., T. Horrex—10d.
62. Paper boards, J. F. Jones—4d.
63. Jack and slubbing frames, A. Barlow—10d.
64. Creating guano, T. Richardson and M. D. Rucker—4d.
65. Lighting street and other lamps, J. Welch—10d.
66. Bits for horses, L. Weber—4d.
67. Taps, J. Calkin—4d.
68. Manufacture of tobacco, W. Davies—8d.
69. Flyers for spinning, R. A. Lightoller and G. H. Lightoller—4d.
70. Theodolites, E. P. Bidder—8d.
71. Fireproof safes, F. Weiss—4d.
72. Photography, K. Pettitt—4d.
73. Lint, S. S. Brown—4d.
74. Cutting match splints, &c., J. C. Brown—8d.
75. Hydrometers, R. W. Ladd and L. Gertling—4d.
76. Standards for wire fencing, W. Baylis—4d.

* Specifications will be forwarded from the Commissioners of Patents' Office, Southampton-buildings, Chancery-lane, by post on receipt of the amount of price and postage. Sums exceeding 5s must be remitted by Post-office Order, made payable at the Post-office, 5, High Holborn, or Mr. Bennet Woodcroft, her Majesty's Patent Office. We cannot undertake to forward Specifications, or Books advertised from the office of THE ENGLISH MECHANIC.

DUBLIN INTERNATIONAL EXHIBITION.

No. 632—CLASS D—SECTION 22.

PRIZE MEDAL

AWARDED TO

CHATWOOD'S

PATENT SAFE AND LOCK COMPANY

(Limited),

LANCASHIRE SAFE AND LOCK

WORKS, BOLTON,

FOR THEIR

FIRE-PROOF SAFES, LOCKS, &c.

WITH SPECIAL MENTION OF THE

"WEDGE PROOF FASTENINGS"

OF

S. CHATWOOD.

T. E. TAYLOR.

MODELLER OF NEW INVENTIONS,
LATHE, TOOL MAKER,
AND GENERAL MACHINIST,
110, FETTER-LANE, FLEET-STREET, LONDON, E.C.
Patterns made to drawing.

TO CONTRACTORS, ENGINEERS, SHIP BUILDERS, COLLIERY OWNERS, &c.—Sections and Prices forwarded on application for Boiler, Bridge, Boat, and Ship Plates, Angle, Tee, beam, Girder, and Dock Iron of all sizes; Sheet Iron, Plain, Corrugated, or Galvanised; Wire Rods for drawing, telegraph, or fencing; Black or Galvanised. Wire Ropes; Permanent, Colliery, or Tram Ralls; Hoop Iron, Bar Iron, Nail Rods, Split Nut Iron, Outer, Bevelled, Taper, Convex, Half Round, Bash, Tyre, and all descriptions of Fancy Iron; Bar Iron of all sizes; Wrought iron Forgings, Castings, and Railway Material of every description.

JOHN HORSLEY,
Iron Agency Office,
3, ST. ANN'S SQUARE, MANCHESTER.

WHEEL, RACK, and SCREW CUTTING.
SPUR, BEVEL, RATCHET, WORM and INTERNAL WHEELS cut to any size or number of teeth; also racks of any length or pitch. Dividing plates drilled or lined. Screws cut to any size or pitch. J. Wilkinson, Engineer, St. George's Works, 83, St. George's-road, S. London.

"THE ARTIZAN."

PATENT OFFICE & DESIGNS REGISTRY,
(Office of "The Artizan" for Scotland).
W. R. M. THOMPSON & Co., 30, Buchanan-street, Glasgow,
Consulting Engineers and Patent Agents.

In connection with
WILLIAM SMITH, Esq., C.E., Director of the Artisan Patent Office, London, Proprietor and Editor of the "Artizan," a Monthly Record of Engineering and the Industrial Arts, TRANSACT ALL BUSINESS RELATING TO BREVETS AND FOREIGN PATENTS FOR INVENTIONS, AND THE REGISTRATION OF DESIGNERS, AND EXECUTE PLANS AND SPECIFICATIONS OF ALL KINDS OF MACHINERY IN THE MOST CONDUCT MANNER, AT THE LOWEST POSSIBLE CHARGES. Provisional Protection, 25 5s. Ordinary Charges for Complete Patent, 24s.

All general information in reference to Patents given free on personal application, or by letter, when an addressed stamped envelope is enclosed.

The "Artizan" supplied, and all business for it in Scotland may be transacted at the above Office, 30, Buchanan-street, Glasgow.

A MARVEL OF CHEAPNESS.—THE
newly Invented POCKET TIMEPIECE, with handsome gilt case, and an elegant enamelled DIAL, interspersed with gold, price 1s. by post 14 stamps.—JOB MALPASS, Kidderminster.

WEALE'S SERIES.

Catalogue on Application.

CRANES AND MACHINERY FOR RAISING
HEAVY BODIES, by J. Glynn. 1s.

STEAM ENGINE, by Dr. Lardner. 1s.

TUBULAR AND IRON GIRDER BRIDGES,
by G. D. Dempsey. 1s.

LIGHTHOUSES, their Construction and Illumination,
by Allan Stevenson. 3s.

STEAM BOILERS, their Construction and Management,
by R. Armstrong. 1s. 6d.

RAILWAYS, Construction, by Sir M. Stephenson.
Capital and Dividends, by E. D. Chatterway. 2s. 6d.

London: VIRTUE, BROTHERS, & CO., Amen Corner.

FOR THE
PROTECTION
OF
LIFE
AND
PROPERTY

Thames-street

HOLLOWAY'S OINTMENT AND PILLS.
GOOD NEWS.—Honour, title, wealth, or station may be desirable possessions, but they are not like health necessary to man's happiness. The former may be difficult of acquisition, the latter is almost always to be had at little cost with moderate perseverance, and fair attention to the directions wrapped round every pot and box of Holloway's remedies. With these in hand we may advance fearlessly through many dangers that beset us, and we may feel confident that when used early, these preparations will infallibly dispel disease, and restore the patient to health, strength, and soundness.—These noble medicaments will cure sores, bad legs, enlamed joints, &c., release the victim from the painful present, and a hopeless future.

UPFIELD GREEN,
JOINERS' HALL BUILDINGS, 79, UPPER THAMES STREET, E.C.,
LITHOGRAPHER, PRINTER, ARTIST, AND DESIGNER,
 PLANS, DESIGNS, SPECIFICATIONS, AND EVERY DESCRIPTION OF ENGINEERING DRAWINGS EXECUTED WITH
 RAPIDITY AND ECONOMY.

Estimates Forwarded for All Kinds of Turret Clocks.

Estimates Forwarded for All Kinds of Turret Clocks.

GOLD FROM 6 GUINEAS. **SILVER FROM 3 GUINEAS.**

TUCK'S PATENT STEAM PACKING.
TUCK'S PATENT ELASTIC PACKING AND METALLIC LININGS FOR STEAM-ENGINES, PUMPS, &c.
 ADVANTAGES.—A more perfect vacuum is obtained, Friction reduced, great saving in oil and tallow, and the Packing is gradually and completely worn away without becoming hard, thus obviating the necessity of drawing the old Packing.

J. H. TUCK & CO., 35, CANNON STREET, E.C.
VULCANISED INDIA RUBBER GOODS.
 VALVES, WASHERS, HOSE, MILL BANDS, &c.
J. H. TUCK and CO., 35, CANNON STREET, E.C.

SCREW CUTTER'S GUIDE.
 Price 1s. 6d., or stamps.
 Containing 115 Pages and nearly 2,000 Trains of Wheels, all different threads and pitches.
 Tables for Tap making for Engineers, 1 to 6 inches, Gas Taps 1/2 in. to 2 inches, Mr. Whitworth's thread and make.
 A Lithograph showing a new radius gear invented by the author of this work.
 May be had at James Martin, 19, Wilson-street, New Cross-road, Deptford, Kent.

PLANS, ELEVATIONS, &c., Made, Copied, Traced, Reduced, or Enlarged, in the best manner, at moderate charges, by J. J. GREENE, 63, Upper Stamford-street Blackfriars.

STANDARD GAUGES, Surface Plates, Straight Edges, Scales of Length, and other Instruments of Precision, of real accuracy and of all sizes.
H. GARSIDE, 17 Coupland-street, Oxford-street, Manchester.

To Electricians.
GIAS CARBON (not compressed) Cut in Plates
 or Blocks for Batteries.
 Price Lists on application, with stamped envelope.
 No. 14 COVERED WIRE PRIMARY (Tested) per lb. 3s. 6d.
 No. 35 SILK SECONDARY, do. 14s. 0d.
P. HENDERSON, 3, Park-hill, Clapham, Surrey.

SMITH'S PATENT WIRE ROPE AND CABLE MACHINE, guaranteed to produce Four times the usual quantity of Work, of Superior Quality, at One-Third the Cost for Labour.
 REFERENCES TO ALL THE PRINCIPAL ROPEMAKERS IN THE KINGDOM AND ON THE CONTINENT.
 Every description of Machinery and Repairs at Reasonable Prices.
ARCHIBALD SMITH, 69, Princess-street, Leicester-square, W.

SECOND-HAND CASES OF MATHEMATICAL INSTRUMENTS, Theodolites, Levels, Pentagraphs, Quadrants, Sextants, Universal Dials, Protractors, Circumferencers, Prismatic and Beam Compasses, Ivory and Boxwood Scales, Land Chains, &c., by Troughton and Simms, Elliott, Dolland, and others, at WM. LAWLEY'S, 78, Farringdon-street, City. Photographic Cameras, Lenses, Magic Lanterns, Slides, Dissolving View Apparatus, Microscopes, Telescopes, Opera, Race, and Tourist's Glasses, by Voigtlander, Ross, Dallmeyer, and others. Instruments bought or exchanged. Catalogues forwarded on receipt of three stamps for each.

C. SUFFELL, MATHEMATICAL INSTRUMENTMAKER, 11, BRIDGE-STREET, WESTMINSTER, begs to call attention to his improved Levels and Theodolites, as manufactured for Her Majesty's Government. The pocket sets of Instruments, from 16s. to 42s.; Telescopes, 5 miles range, from 6s. 6d.; 10 miles ditto, 8s. 6d. and 10s. 6d.; Boxwood scales, engine divided, 2s. 6d.; T squares, 1s. to 5s.; Measures and Rules of all nations. Post-office orders payable at Charing Cross branch. Lists of prices forwarded on application.

THE LONDON DRAWING ASSOCIATION for supplying Engineering, Mechanical, Architectural, and General Drawing, Designs, Maps, Plans, Tracings, Wood Engraving, Electrotyping, 7, Duke-street, Adelphi, London. Enclose stamp for prospectus.

"EXCELSIOR," "EXCELSIOR"
Family Sewing & Embroidering Machine
 WITH ALL THE LATEST IMPROVEMENTS.

IS easy to operate, simple to learn, quiet in action, and not liable to derangement. It will TUCK, HEM, FELL, GATHER, CORD, QUILT, BRAID, and sews from two ordinary reels, requires no re-winding, and the seam, if out at every inch, will not rip. Price from £6 6s.

WRIGHT AND MANN, 143, HOLBORN BARS, LONDON.
 MANUFACTORY—GIPPING WORKS, IPSWICH.
 PRICE LISTS FREE.

Crickmer's Patent Plastic Metallic Packing.
 FURTHER REDUCTION IN PRICE ON AND AFTER OCTOBER FIRST.
 PATENT WIRE GAUZE JOINT PACKING... .. 1s. 6d. per lb. INDIA-RUBBER CORE PACKING (HEMP)... .. 1s. 4d. per lb.
 CRICKMER'S PATENT PACKING... .. 2s. 3d. Do. Do. (COTTON)... .. 2s. 6d.
 This Packing takes less Tallow to lubricate it than any other, and being a Pliable Metallic Surface requiring but little Pressure to keep it Steam tight, there is a great saving in friction.
 PATENT TALLOW PUMPS AND LUBRICATORS.
 WELL STRETCHED LEATHER MILL BANDS, HOSE PIPES, FIRE BUCKETS, VALVES, WASHERS, &c., &c.
 CAUTION.—Engineers, Millowners, and others are Cautioned against Purchasing a Spurious Metallic Packing, purporting to be Crickmer's. THE GENUINE CAN ONLY BE OBTAINED FROM
ALEX. ROSS AND CO.,
 GRANGE ROAD, BERMONDSEY, the only Authorized Agents. Price Lists on Application.

PATENT HOLLOW STEAM PACKING.

THE great and peculiar advantages of this packing consist in its remaining perfectly elastic, and in so constructed and applied that the pressure of the steam itself makes the joint by entering the packing from the cylinder; thus the many objections to packing previously existing are effectually removed. Vulcanised India-rubber Sheet Washers, Valves, Springs, Hoses, Glazed and Solid Tubing for Gas, Speaking Tubes, Diving Dresses, Gas Bags, Air-proof Goods, or any description of India-rubber articles made to order.

Price list or circular, with full description of packing, to be had of the only Manufacturers and Patentees of Hollow Steam Packing.

FOSTER and WILLIAMS, India-rubber Works, Cowper-street, City-road.

Apply to EDWIN H. NEWBY,
31, CHURCHILL, and LEICESTER.

The above Lubricators grease every particle of steam previous to its passing through the valves into the cylinders.

INVENTIONS PROTECTED BY
PATENT OR REGISTRATION, at fixed and most moderate charges. "The Inventors' Manual" free by post, or gratis on application.—Apply to Mr. BREWER (late Barlow and Co.), 89, Chancery-lane, London, W.C. Established 21 years.

INVENTORS ASSISTED

IN Securing, Carrying Out, and Disposing of their Inventions.—Apply to Messrs. B. BROWNE and CO., British and Foreign Patent Office, 48, King William-street, London-bridge.

A Pamphlet gratis, on Cost of Patents, may be had on application

INVENTIONS secured by Patent or Registration, on moderate terms, by application to Mr. WILLIAM BROOKES (of upwards of 25 years' experience in such matters). British and Foreign Patent Agency, 62, Chancery-lane, London, W.C.

TO INVENTORS.—GENERAL
PATENT OFFICES.—L. de FONTAINEMOREAU, 4, South-street, Finsbury, London; 18, Rue de la Fidélité, Paris; 32, Rue des Minimes, Brussels. Provisional protection, £7; to complete patent, £30; French patent, £6 10s.; Belgium, £2 10s. Circular gratis on application.

PATENTS FOR INVENTIONS.—Full instructions may be obtained by applying to Mr. W. T. RAWLE, Office of British and Foreign Patents, 8, Small street, Bristol.

NOTICE TO INVENTORS.—Office for Patents, 4, Trafalgar-square, Charing-cross. Printed instructions (gratis) as to the Cost of PATENTS, for Great Britain or foreign countries. Advice and assistance in disposing of or working inventions. Branch offices and agencies in every Continental State and in America. Established 30 years. Full information as to expired or existing Patents at home or abroad. Apply personally or by letter to Messrs. PRINCE and Co. Patent Office, 4, TRAFALGAR-SQUARE, CHARING-CROSS, W.C.

Self-acting, Turning, and Screw-Cutting Lathes, OF THE FOLLOWING SIZES,

For Sale, and Ready for Delivery:—

Height of Centres.	Length of Bed.
6½ Inches.	6 Feet.
7 "	8 "
7½ "	14 "
8 "	8 "
8 "	12 "
8 "	13 "
10 "	16 "
11 "	16 "

Also a large Assortment of Single and Double Geared Drilling and Boring Machines; Planing, Shaping, Slotting, Bolt Screwing, Punching, and Shearing Machines; Hydraulic Jacks, Screw Jacks, and other Tools.

Apply to W. BLACKETT, Hope Iron Works, 106, Southwark Bridge Road, London.

E. BOURDON'S PATENT GAUGES.—GIFFARD'S INJECTORS.

Drawings and Prices on Application to

W. T. HENDRY, & Co., 73, QUEEN STREET, LONDON, E.C.

BRITISH AND FOREIGN PATENTS AND THE REGISTRATION OF DESIGNS.

Mr. H. H. MURDOCH having succeeded to the Business of his late Father, which has been established upwards of Thirty Years, offers his professional services to inventors. A circular, containing full information respecting the various modes of securing protection for inventions at home and abroad, may be had, Gratis, by applying (personally or by letter), at his OFFICE FOR PATENTS, 7, STAPLE INN, LONDON.

PATENTS.

MR. VAUGHAN, Member of the Society of Arts, British, Foreign, and Colonial Patent Agent, 54, Chancery-lane, W.C. Transacts every description of business connected with Letters Patent for Inventions. Provisional protection, 6 to 8 guineas. A "Guide to Inventors" free by post.

THE ENGLISH MECHANIC:

A Record of Mechanical Invention, Scientific and Industrial Progress,
Building, Engineering, Manufactures, Arts, &c.

VOL. II.—No. 36.]

FRIDAY, DECEMBER 1, 1865.

[PRICE ONE PENNY.]

BYRNE'S ADJUSTIVE GOVERNOR.

THE principle of this governor, previously slightly noticed in THE ENGLISH MECHANIC, is, that the centrifugal force of the revolving pendulums is equilibrated at any required speed by the force of gravity of an adjustable counterweight, or the tension of a spring. The principle is not affected by the number of pendulums, but four obviously has double the power of two, revolving in the same space, besides presenting a better appearance, and a greater number would be attended with practical inconvenience; for these reasons the adjustive governor is constructed with four pendulums, each having a crank springing from the joint at right angles, which are connected by rods to a sliding cylinder having a steel centre let into the top; by these means the divergence of the pendulums raises the sliding cylinder, which, acting on the steel centre, communicates motion to the valve. It is not a condition for its efficient action that the throttle valve should be in a position shown in the

diagram; but in selecting position, regard should be had for the friction and inertia of the intermediate gear; a great quantity of it impedes fine action, therefore the simplest arrangement that circumstances will permit acts best.

Fig. 1. Vertical section of the revolving portion. Fig. 2. Horizontal section at base. Fig. 3. Horizontal section of spindle at pendulum joints. Fig. 4. Horizontal section of centre guide. Fig. 5. Horizontal section of steam pipe and throttle valve. Fig. 6. Horizontal section of cylinder at joints.

(a) A wrought iron spindle or stalk, having a disc at (h), with six holes in it, to enable it to be bolted to a similar disc, on a vertical shaft of length dependant on circumstances. (b) A bulb forged on the stalk, having two thorough mortices in it, crossing each other at right angles, thereby forming four joints with the crank pendulums; the arrangement of the pins in those joints gives mutual security, for

even if the split pin and washer of any of them flies out, the joint-pin cannot get away, because its head will come in contact with the point of its successor, which must be backed considerably before it can pass. (See fig. 3.) (c) A brass cylinder, moveable vertically on the spindle, which is made hexagon in section at that portion in preference to feather keys. There is an oil hole in the cylinder at (d), which must be left open, as it answers for an air passage also. (e) A steel concave centre driven into the cylinder. (f) A sliding centre, moveable vertically through the guide, the bolts of which are left extra in length, to enable it to be bolted to a bracket or stay from any convenient place. (g g g g) Four balls, each fixed on its pendulum by a nut fitted into a recess in the ball. (h h h h) Four guides forged on a centre ring, which is keyed on the disc; each pendulum is made wider at the portion which comes in contact with the guide, to present a good bearing

surface: by that means it will not be liable to sink itself a recess in the propelling side of the guide.

(i) A strap bolted to the steam pipe, forming a bearing for one end of the valve spindle, to take the overhanging strain off the gland. (j) A regulating lever, having an arc of traverse of the same number of degrees as the arc of one of the revolving pendulums. (k) A counterweight, which is fixed at the upper portion of the lever for the slowest speed, and fixed at the lowest point for the highest speed, the intervening points controlling intermediate speeds; a spring balance may be substituted for the counterweight, by attaching it to the regulating lever and a fixed point at a convenient distance. Now admitting the engine to be working at the required speed, if it receives a check through work being suddenly put on, the pendulums lose a portion of their sustaining power, of which the counterweight will take advantage by depressing them, and opening the valve, thus admitting a greater supply of steam, which will prove a check on the error; or if the engine increase its speed through deficient work, or increase of steam pressure, the pendulums will acquire more centrifugal force, consequently increase their angle of divergence, raising the counterweight, and closing the valve, thus reducing the supply of steam until the increasing speed is effectually checked. It is evidently instantaneous in its action, for the counterweight keeps a continual pressure on the steel centre, therefore the immediate gear is always tight, so that the slightest variation of the pendulums is at once communicated to the valve. It is advisable to gear it to revolve at a speed high enough to cause the normal angle of divergence of the pendulums to be at least 90°, but it may be geared at a much higher speed with advantage, the only limit being the strength of material in its construction; hence its power can be increased to suit circumstances, and it becomes more sensitive to an error by gearing it at a high speed, and using a correspondingly heavy counterweight. Its capacity for maintaining various speeds will often prove advantageous, especially to the smaller class of engines, where the nature of the work sometimes requires a higher speed than at others; the adjustable governor gives full scope for any such alteration of speed, as the length of regulating lever allows that its maximum number of revolutions shall be double its minimum; the numerical range being determined by the size of the counterweight, it can be made heavy or light to suit the boiler power. From this it may be seen that the higher the range of speed required, the more the regulating lever must be weighted, consequently the revolving pendulums become more depressed, which is rather anomalous; but as the regulating lever gives a gradually increasing weight on being raised, the same amount of centrifugal force cannot raise it to the same height when the weight is heavy as when it is light, consequently the lever not being raised, the valve remains open to a greater extent, admitting a greater supply of steam, which gives the higher speed. Its advantages over the ordinary governor can scarcely be questioned, when it is so well known that they are never trusted with the command of the steam; with the present one this is not so, it must have the steam at its disposal, and in sufficient quantity as to be able to counteract any possible check which the engine may receive through work being suddenly put on. In engines with the ordinary governor, the stop valve is the regulator of the speed; and when the work is very variable, it is necessary to station an attendant by the stop valve to give more steam when the work is put on, and reduce it when the work slackens, otherwise the engine would be either brought up, or increase its speed to such an extent as might damage the machinery. The adjustable governor proves a more effectual regulator than any attendant can possibly be, for by its sensitiveness and power, the instant an error occurs in the speed, the throttle valve is moved to such an extent as effectually checks it. Errors there must always be, for it is the very fact of a variation of speed which brings the governor into action; but if errors cannot be prevented, the governor can be made so sensitive as to be applying the remedy in the same instant that the error commences, thereby reducing the possible variation of speed within so limited a compass, as to be almost imperceptible, and undoubtedly sufficiently uniform for all practical purposes.

ATMOSPHERIC PRESSURE ON THE EARTH.—On the computation that the earth's surface consists of 198,943,750 square miles, it contains 616,248,160,000 square yards, 5,546,234,440,000 square feet, or 798,687,615,360,000 square inches, the pressure on which, at fourteen and a half pounds the square inch, would be 11,580,535,422,720,000,000lb., or 5,169,873,403,000,000 tons.

ANSWERS TO CORRESPONDENTS.

ALL letters intended for the Editor should be addressed to 75, Fleet-street.

LETTERS applying for information to be furnished by post cannot be attended to.

CORRESPONDENTS are requested to keep copies of their drawings and manuscripts, as the Editor cannot undertake to return such as may be rejected.

GLASGOW WEST.—You had better enter into an arrangement for a supply from some respectable manufacturer. It will never pay to make in small quantities.

CORNISHMAN.—Write to Spon, publisher, Bucklersbury; to Lockwood, Stationer's Hall-court; or Weale, High Holborn.

C. T. WHITMELL.—Received; but you will see that the subject has been already fully discussed.

WASHER.—Try Houlston and Wright, publishers, 65, Paternoster-row.

T. A. J. (Wokingham).—You can get such a piece cast at any brass-founder.

J. T. T.—Such a work was published by Weale, High Holborn.

PIANO.—We know of but such works as you mention. We never heard of one giving the construction of the entire instrument. A full description would require many diagrams.

DAVID SLOAN THOMSON.—Received.

T. A.—Information in any London Directory.

TIN FOIL.—Through any wholesale house.

C. SIMPKINS (Reading).—The apparatus was illustrated in a recent number of the *Journal of the Society of Arts*.

F. G.—No. 16, Bucklersbury. We think Naylor's good, and should give them preference.

HYDRO PNEUMATIC.—Your theory is correct, but far from possessing novelty.

CYMO.—Your best method is to advertise in the *Mechanical Journals*. There are many applicants for such situations. The twist drills are manufactured in America. We do not know of any agency in England.

A. YOUNG ROLL TURNER.—We do not know of such a work. The price varies according to the material and finish. Write to the manufacturer for a price list.

EDMUND ORGAN.—Received. Many thanks.

A. CONSTANT READER.—Write to Spon, the publisher, of Buckersbury.

PROCEURABLE.—It is a business to which an apprenticeship must be served. For bronzing, see *ENGLISH MECHANIC*, page 105, No. 35.

A. McKEE.—Received. Answered by other correspondents.

H. M. (Greenwich).—Advertise in the *Illustrated Builders' Journal*. Thanks for your communication, but: "A Draughtsman" has already been answered.

DAVID KNIGHT.—Thanks for the information sent. We are about to crowd in for want of space. Other letters will be noticed early.

W. J. D. E.—Look at pages 105 and 106 of "Tate's Mechanics," and at page 62 of Chas. D. Abel's work, in Weale's series, you will find all you require.

DRUGGSMAN.—Look at page 34 of Vol. II. of the *Chemical News*, you will find the receipt.

T. H. B.—Try strong acid and water.

JOHN TURNER, of No. 32.—If you mean coloured flames, see Vol. I., page 41, and Vol. III., page 144, of the *Chemical News*.

T. G. (Darlington).—You are perfectly correct in judging that the answer "received, but unable to spare space" referred to your own letter. Mr. Wegg's letter was inserted as a communication only, and not as an editorial article, and we must beg you to address your complaints to Mr. Wegg at his private residence. We are perfectly willing to insert any communication on the subject forwarded by Mr. Slugg himself, but we object to letters by deputy, and decidedly consign them to the waste paper basket, when they assume the appearance of free advertisements.

. We have to ask our correspondents to sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them by the thousand; the same with "Well-Wisher," &c. Several letters remain over till next week for answer.

LOCOMOTIVE BUILDING IN CALIFORNIA.—The first locomotive ever built in California has just made its trial trip on the San Francisco and San Jose Railroad. The cylinders of this locomotive are 16in. in diameter, with a 24in. stroke; the driving wheels 5ft. in diameter, length of locomotive 26½ft. over frame; diameter of boiler 44in., containing 141 two inch tubes 11ft. in length; total weight of locomotive 30 tons. The locomotive drew four cars, containing 300 invited guests, and on the return trip made two miles in 108 seconds, the best time yet accomplished on that side of the Rocky Mountains.

ROAD LOCOMOTIVES IN FRANCE.—The locomotive to be used on ordinary roads, constructed by M. Lotz, of Nantes, has successfully performed the tasks imposed on the inventor by the commission appointed by the Government to examine and report on this new mode of traction. A few days since the locomotive, drawing an omnibus built for the purpose, set out from the Champ de Mars, crossed the "Trocadéro," continued its course along the entire of the Bois de Boulogne, and returned to the Champs de Mars by the avenue of St. Cloud, the avenue of the Champs Elysees, the boulevard and the bridge of the Alma, without any accident.

TO OUR READERS.

We have recently received many letters from cabinet makers, mathematical instrument makers, joiners and others, complaining that we set apart no portion of *THE ENGLISH MECHANIC* for articles and correspondence on their especial trades. We beg to inform our readers and correspondents that our columns are open to communications from workmen of every description—the more the merrier—but they must be of a strictly practical character.

THE ENGLISH MECHANIC.

Every Tuesday, One Penny. Monthly Parts, 5d. Now Publishing, complete, the First Volume. *.* Title Page and Index, One Penny. Cases for binding, One Shilling and Sixpence. It is solicited that all back Numbers be ordered at once.

All the early Numbers have been reprinted. It is therefore necessary that sets be made up at once, as there will be no further reprints owing to the great expense they entail.

147, FLEET-STREET, LONDON, and all Booksellers.

OUR MONTHLY PARTS.

Part 8 of *THE ENGLISH MECHANIC*, in coloured wrapper, is now ready.

Price 6d. only! Post free, 7d.

All back Nos. have been reprinted, and can be had direct from our Office, or through any bookseller.

NOTICE TO ADVERTISERS.

An Advertisement Canssaver named BUTLER has no authority from the Proprietor of the "English Mechanic" to collect money from Advertisers or others.

THE ENGLISH MECHANIC!

Just Ready, and now Publishing, the

FIRST VOLUME

of

THE ENGLISH MECHANIC.

A Record of Mechanical Invention, Scientific, and Industrial Progress.

UPWARDS OF ONE HUNDRED ILLUSTRATIONS.

Handsomely bound, only 4s. 6d.; post free, 5s.

OFFICE, 147, FLEET-STREET, LONDON, and all Booksellers

TO ADVERTISERS.

As the *ENGLISH MECHANIC* addresses itself to the largest and most intelligent portion of the community, and is the only Paper of the kind established, it offers unusual advantages as an advertising medium.

SCALE FOR ADVERTISEMENTS:

	s.	d.
Five Lines	0	3
Every additional Line (Nine Words)	0	6
Whole Page	8	0
Half Page	4	0
One column	3	0
Post-Office Orders to be made payable to GEORGE MADRICK, Fleet Street Branch.		

Advertisements to be sent not later than Friday. Letters to the Editor to be forwarded to 75 Fleet-Street.

The English Mechanic.

FRIDAY, DECEMBER 1st, 1865.

POLISHING AND BLUEING HARD AND SOFT SCREWS.

IT often happens that, with all the accommodation necessary for the purpose, the amateur and workman is often at a loss for a knowledge of the wherewithal to accomplish the purposes above noted. Though in various articles published in our columns there might be picked out information on one or two points connected with our subject, still enough has not been given in the lump to serve as a sufficient guide. A correspondent, labouring under the same impression, has forwarded us a long communication, from which we eliminate the following:—For polishing and blueing screws the materials are:—Screw head tool and chucks, one smooth and one old 5-inch pottame file; a smooth-cut file burnisher, 5 inch; a strip of "arcanser" oil-stone; screw-head files, according to size of screws; a strip of greystone, one of bluestone—each about 6-inch long and 1-inch square; strips of iron and bell metal, 6 inch long ½-inch wide, ¼-inch thick; a smooth-cut knicking

file, a piece of brass 2-inch diameter, thin, with 5-inch handle; a piece of brass, $\frac{1}{2}$ -inch thick, $\frac{1}{2}$ -inch diameter, with holes the size of the taps of screws; small quantities of oilstone powder, sharp crocus and red stuff, also fine red stuff, but not too fine; strip of dogwood, 6-inch long, 1-inch square; French buff; small quantity of finest flour emery; a good spirit lamp; cleaning-off medium, or prepared bread. (For this, take a bit of bread, size a walnut—dip it in clean water; squeeze water out; knead up before the fire or in spirit lamp, but do not scorch, only drive out superfluous moisture, and make a dryish dough; keep in a porcelain box.) To polish screws (soft):—File screws up to shape, polish first with greystone, and oil and finish with blue-stone and oil; clean off with the bread, wipe the moisture off with piece of leather; clean the burnisher on the board with emery, taking care no emery remains on the burnisher; rub the head of the screw, gently pulling the bow one way only. If the screw is large, and the burnisher scratches, rub a little wet soap on the burnisher; you can then rub hard, and pull the bow both up and down. Having polished and burnished the screws, bread off the oil, throw them in some slaked lime; then brush off the lime, place the brass with the holes in it on the blueing pan, and place not more than one screw at a time thereon; hold the pan over the spirit lamp or gas jet, taking care there is no current of air setting towards the same, and that the flame is equal round underneath the pan, for otherwise the screw will not colour equally. If the screw be large, and a good blue is desired, it must be taken off a little before the required colour appears. To polish and blue hard screws: place the screws, two or three at a time, on a piece of charcoal, and blow to a bright red with a blow pipe flame, drop them in some oil; after hardening, bend a piece of bending wire, so as to hold the screw with some oil; hold it in the flame until the oil takes fire, remove it, and, as soon as the blaze dies off, drop the screw in the oil. (Care is required, or the screw will be too soft, or dangerously hard, though, from some purposes, screws are polished quite hard.) Place the screws in the tool, polish with "arcasser;" if the edges are showing, do them with iron and oilstone powder; next, a piece of soft wood and oilstone powder—the powder having been mixed with just as much oil as it will absorb. Mix, also, the sharp and fine red stuffs as thick as they can be mixed, on steel blocks sold for this purpose, to be kept clean. Having polished out the file marks with oilstone, file clean with smooth file, and the bell metal; use small quantities of sharp stuff, or the iron can be used; this brings a polish ready for the bell metal and fine stuff. Next, file the surface off the dogwood, put on a very small quantity of fine red stuff, rub the screw a few times on it; this gives finish and colour, and a better blue will take on blueing, as before. A piece of good clean wick is a good thing to use for placing the red stuffs on the polishers; elder pith to further clean the heads, to enable the polisher to see the progress made. All the tools are readily to be had—for instance, from Grimeshaw, of Goswell-street, London; or from Swinden, in Temple-street, Birmingham. Screw-head tools range from 7s. to 15s.; bell metal, 1s. 4d. per pound; oilstone dust, 8d. per pound; red stuffs, 8d. per oz.; pith bundle, 2s.; dogwood, in sticks, 2d. to 6d. each; and glossing stuffs, in boxes, 8d. to 3s. each, according to size.

CHEAP GAS.

FOR years, many years, the quality of the gas supplied to the consumers of the metropolis has been wretched—compared with that supplied to many other towns; and for this article an extraordinarily high price has been paid, the minimum being now 4s. 6d. per 1,000 cubic feet. At various times spirited individuals have endeavoured to organize opposition to the various companies, and have failed from want of support; interested promoters have "got up" companies after copious preamble, have pocketed "considerations," and allowed their promising "opposition" to collapse, and a reliant public to be well, to use a mild term—rendered distrustful of any more such schemes. Still, it remained a fact that the gas was bad and dear, and that it could be had both better and cheaper.

The Corporation of London, after a deal of humming, and hawing, have arrived at the same opinion as their *clientelle*, and have determined to make gas for the City. Accordingly, application is to be made to Parliament for all the necessary powers in the ensuing session.

Many efforts have been made to prove that, owing to various circumstances—never very clearly set before the public—it was impossible to make the gas

either cheaper or better: whence these statements emanated, required no very little difficult guess work. Yet it is a remarkable fact that no man of our acquaintance has ever yet been able to get at the exact dividend paid to the holders of gas stock, though there is no doubt about its being a very good one, and, evidently, the Corporation of London are of opinion that a much less will pay for their proposed venture. Signs are not wanting that, afraid of the Corporation, the companies are coming to their senses, are willing to give up an immense share of their profits to the public, with a promise of more. From Christmas the price will be reduced by the City Company from 4s. 6d. to 4s., and "the directors anticipate the increase in the demand for gas consequent on this reduction will enable the company, at no distant period, to effect a further reduction."

If the companies think that by this concession the Corporation will be deterred from pursuing their scheme, we are inclined to believe they will find themselves very far mistaken. Quite as much, also, as they will find it impossible to compete with the Corporation in the manufacture of the article. Because the Corporation works are intended to be erected down the river, where land is cheap, compared with what it is in this city's vicinage; the cost of coals laid down at the works will be considerably less, and advantage will be taken of the very latest improvements in gas-making, combined, we believe, also with self-charging and discharging retorts. And here we would advise such of our readers as have improvements in hand, we know several have, to keep their eyes open, and at the proper time, place themselves in communication with the City officials.

In competition, we have as good a guarantee for quality as under monopoly; most decidedly, we have a superior one for price and for quantity. And, viewing the matter in this light only, we wish all success to the Corporation—though we should have the streets up for the next three years! and a due quantity of comfort and solace to the various stock and shareholders in the existing companies under the reduction of their dividends and bonuses.

COMBINATIONS OF THE STEREOSCOPE AND THE PHENAKISTISCOPE.

MR. A. CLAUDET, in a paper on moving photographic figures, illustrating some phenomena of vision connected with the above combinations, by means of photography, says that from the beginning of photography it must have struck those who were acquainted with the phenakistiscope, invented by Plateau, that photography could produce with advantage series of pictures for that instrument with greater accuracy than any made by hand. When, at a later period, the stereoscope had become popular, there was a still stronger incitement for desiring to make use of that process to produce binocular pictures for the phenakistiscope in a way to combine the stereoscopic effect with the illusion of moving figures. M. Duboscq made some ingenious attempts in this direction, however not perfect; for in his revolving disc the two series of pictures do not move with the same velocity on account of their being placed on two zones of different peripheries, which produces a sort of confusion and distortion in the representation of the object during its movement. In his revolving cylinder, this defect does not take place; but the pictures being curved like the cylinder is a most unfavourable disposition for examining them in the stereoscope. About the same time Mr. Claudet had also turned his attention towards the subject, and had practically experienced the difficulty of obtaining together the phenakistiscope and stereoscopic effects without similar defects. The instrument was first exhibited to show how easy it was to obtain the illusion of moving figures without stereoscopic effect, two pictures being sufficient to elicit the phenomenon, although the illusion of reality suffers from the abruptness of two extreme movements, and from the deficiency of intermediate positions. Nothing, however, is easier than to employ eight different pictures in as many different stages of the action: and with this number the effect will be sufficiently complete. For this, Mr. Claudet, having placed in his stereoscope two separate cubic frames, has only to fix on their four sides, at right angles, two sets of four pictures, making eight pictures, which are made to pass in consecutive order before the lenses, and the figure assumes consecutively eight different stages of the whole action. The instrument in its simple state, with only two pictures, will suffice to illustrate the principle, and, at the same time, elicit some curious phenomena of the perception of vision. It is well known that the retina has the power of retaining for a short time the impression or the sensation of

the image which has struck it. Availing himself of this property, Mr. Claudet has constructed an instrument in such a manner, that by means of a slide, with one hole, he can, by moving it rapidly in a reciprocating horizontal direction, shut one lens while the other remains open; and in continuing that motion, while one eye sees one of the two pictures, the second eye cannot see the other picture. If, before the sensation of one eye is exhausted, the slide shuts one lens and opens the other, a new impression is produced on the retina, and we have an interrupted sensation of vision as if the object had been moved before us; and if a sufficient number of pictures represent that object in the various consecutive positions it has assumed during several stages of its motion, we experience on the retina the same sensation as we have when we see the object itself while it is moving; and although the pictures in their limited number do not and cannot show all the intermediate positions of all the stages of a continuing action, still the mind has the power of filling up the deficiency, as it does, if, when looking at a real object in motion, we accidentally wink the eyelids, or an obstacle happens to pass between us and the object. To exemplify this, Mr. Claudet has constructed two pictures, one representing the beginning of an action, the other the end. By moving the slide one way, the right eye can see the pictures representing the figure in one position, while the picture showing the other is invisible to the left eye; then by moving the slide the other way, the left eye sees the figure in the second position, and the first picture is invisible to the right eye. Although we have really only seen the figure in two extreme positions, still we have had the illusion of having observed the intermediate positions—as, for example, in a slide exhibited having one picture of a boxer with his arm close to his side as preparing to hit, and another with the arm extended delivering the blow. Here, although all the intermediate positions are omitted which must have been assumed during the act, the mind completes the action. Another curious phenomenon of this alternate vision is that one cannot distinguish which eye the object is seen by.

HARDENING AND TEMPERING STEEL.

THOUGH at different times we have directed attention to this matter—only the other day giving some common examples—we continue to have inquiries on the matter poured in upon us; showing, either that our pages are not carefully looked over by some correspondents, or that something more is required from us. We incline to the latter opinion. To do justice to the matter we have to cull from various sources, and if we do not specify names, it is because we fancy real authorities on mechanical subjects do not care so long as their really useful knowledge is disseminated among those who most require it. All we ourselves contribute to the general fund the general public is welcome to, whether the name of our journal be appended thereto or not, provided those who use it may not claim it as their own.

In this matter there are various points on which all may be said to agree; thus, that scale should be removed from the face of the work, to expose it more uniformly to the effect of the cooler; that the temperature suitable for forging and hardening steel differs with its quality and mode of manufacture—the heat diminishing with the increase of carbon; that coke or charcoal is much better than coal as a fuel—owing to the presence of sulphur in large quantities in the latter; that the lowest available temperature should be employed in each process, the hammering should be applied in the most equal manner throughout, and for cutting tools it should be continued until such are nearly cold; that hardening a second time without the intervention of the hammer is attended with increased risk; and that the less frequently steel passes through the fire the better.

The smallest works are heated with the flame of the blowpipe, and are occasionally supported on charcoal. Those objects which are too large to be heated in this way, and are yet too small to be conveniently treated in the naked fire, have various protections. Thus a sheet-iron box stuck into the middle of the fuel is both safe and cleanly, and in many cases the addition of red fuel in the box is of great value. The work is then governed with long forceps. For long and thin tools, such as engravers' tools, &c., a crucible or an iron pot, from 4 to 6 in. deep, filled with lead and heated to redness is used, and in this the tools are placed—moved about in the mass to equalise the heat. Occasionally a pan of charcoal, powdered, is placed on the fire, and heated to redness, and in this the articles are placed. Many tools are heated in the ordinary forge fire, but this should then consist of cinders in preference to all coal:

furthermore, the bellows should be used previous to the introduction of the work, and plenty of time allowed to get hot. The Sheffield folks use coke both in forging and hardening steel goods. They frequently prepare it for themselves either on the forge hearth or in the open yard. Whichever method be followed, all the parts to be hardened should be brought to a uniform temperature, and this is only accomplished by moving the work through the fire so as to expose all parts alike to its action. The fire is increased in size according to the size of the work. In our opinion practice is the great guide in the matter, and that the learner should acquire his experience not with all sorts of work, but begin at small and proceed gradually upwards—or, as the Scotch song says:—

"Creep awa' my bairnies;
Creep before ye gang."

Mr. Holtzapfel, in his excellent work says, "It is argued by some, that by heating pieces of steel to different degrees, before plunging them into the water, the one heat attains full hardness, the next the temper of a tool fit for metal, another of a tool fit for wood, a fourth that of a spring, and so on. That this view is not altogether without foundation, appears in the fact that if the end of a piece of steel be made entirely hard, the transition is not quite immediate from the hard to the soft part; and Mr. Ross, in making the dividing points for his dividing engine, hardens the end of a longer piece of steel than is required, and forms the point upon the grindstone, exactly at that part where the temper suits, without the steel being let down at all; a practice first employed by Mr. Stanchiffe, a workman formerly employed by the celebrated Ramsden. The hardening by this method however without tempering the scale is confined within such extremely narrow limits as to be nearly useless; thus, it frequently happens that in a number of tools heated as nearly alike as the workman could judge, some few will be found too soft for any use, although they are all intended to receive the ordinary hardness; so as to require letting down, as usual with those tools exposed to violent strains or blows, as screw-taps, cold chisels, hatchets, &c., although many tools for metal, used with a quiet and uniform pressure, are left of the full hardness for great durability. With excess of heat, below the lowest that will suffice, the brittleness rather than the useful hardness of tools is increased; and when no excess of heat is employed beyond that absolutely requisite for hardening in the usual manner, the steel does not appear to be injured, and the colours on its brightened surface are an excellent, and in general sufficiently trustworthy, index of the inferior degrees of hardness proper for various uses." It should further be noticed that less than a certain amount of heat not only does not produce hardness, but, in the opinion of many intelligent workmen, has a contrary effect; but this, we opine, is only true with certain qualities of stuff, and sufficient observation has not been made to determine which with certainty; consequently, with this opinion of the effect, these workmen resort to it as the means of rapid annealing,—not by plunging the steel into the water, and there all owing it to remain till cold, but dipping it quickly, then holding it a few moments in the stream, again dipping, and so on, reducing it in a hasty and intermittent manner to the cold state. And this brings us to the cooling.

In cooling various mediums have been resorted to—currents of cold air, water in various states, oil or wax; and freezing mixtures, flat metallic surfaces, and mercury have been used. Stoddart recommended water of 40°. It appears to be allowed that steel cooled in mercury is the hardest, next that plunged in salt and water, or water treated with acid; next plain water, and lastly oil. Mercury is a good conductor, and the nonformation of steam keeps the two surfaces in contact, which is not the case with water. File makers doctor their water, with what is a secret, though we more than suspect they use in some cases salt, and in others a pinch of white arsenic. By the way, we once saw a bronist put a pinch of fine salt into his crocus mixture, and though he could give no "reason why," yet he maintained it materially affected the quality of the work after it came from the hammer, and there was no doubt whatever about the man being a first-class workman. Respecting water, many are in favour of using that which has been used over and over again even for years, provided it is not greasy, and when the steel is harsh the chill is first taken off it to lessen the chances of cracking. It is much to be desired that some one would analyse the water used in various large establishments—each in its fresh state, and also when it is supposed to be in its best working condition,—notice being taken of the character of the steel produced after passing through each. We think many doubts would be set at rest by this.

The so-called natural spring of John Oldham, who was engineer in his day to the Bank of England, was used by him in hardening the rollers for transferring the impressions to the steel plate for bank notes. This spring consists of a vessel with a true and a false bottom, the latter perforated with small holes; it is filled with water, and a good supply is admitted below the partition, which ascends through the holes, and pursues the same current as the heated portion, which also escapes at the top. We do not know that any one now uses this contrivance, but it may be found useful.

Occasionally, when neighbouring parts are required to be respectively hard and soft, collars are fitted tight upon the work, to protect the parts intended to be soft from the direct action of the water.

But the process of hardening is altogether one of anxiety, as the sudden transition from heat to cold, if it does not often crack the work, frequently distorts it. This latter is the accident which most frequently occurs to larger pieces, which may be said to harden in layers; thus, though the outside may be perfectly hard, as the centre is approached it will be found less and less hard. Often, hours after heavy work is removed from the water, it will crack with a loud report—and it is almost therefore a certainty that the inner part continues to contract after the case is fixed. Again, the contiguity of thick and thin parts is highly dangerous, but the mischief which oftentimes follows their cooling may be avoided, or rather lessened, by binding pieces of metal round the thin parts. So also angular notches are sources of mischief. But, generally, it may be said that the frequency of both cracks and distortions is lessened by the successful management of each step in the manipulation—the original manufacture, and the forging, for instance, so that the mass be equally condensed throughout on all sides. Further, when red hot it is weakest, and liable to accident through incautious handling, and from meeting the cooling medium irregularly; so it is best to plunge the work vertically, for thus less disturbance is risked than when immersion is accomplished in any other manner. Scale should *always* be carefully removed before hardening, otherwise the water or other cooling medium cannot exercise an equal power. Edges should be left thick, and grinding supplement the hammer.

Respecting the heat for tempering, it is well known that between the extremes of hard and soft there are many grades, the most common index for which is the surface. These tints have been given by Mr. Stoddart as under:—

430 deg.	Tools for metal	very pale straw yellow
440 "	"	a shade of darker yellow
450 "	Tools for wood	darker straw yellow
460 "	" and screw taps, &c.	still darker straw yellow
470 "	"	a brown yellow
480 "	Hatchets, chipping	a yellow, slightly tinged
490 "	chisels and other	with purple
500 "	percutive tools,	light purple
510 "	saws, &c.	dark purple
520 "	"	dark blue
530 "	"	pale blue
540 "	"	still pale blue
550 "	To soft for the	still pale blue with a tinge
560 "	above purposes	of green

The first tint is only seen by comparison with a piece of steel not heated. The heat for tempering being moderate, it is often supplied by that part of the tool not required to be hardened. The workman quickly applies a file to test the hardness, then brightens it here and there with an emery stick to watch for the colour; and when this is attained the work is cooled in such a way that the body of the tool may not supply any more heat.

One method of tempering small objects gives rapidly, but it requires dexterity and quickness on the part of the operator. A few inches of the end of a flat bar of iron about 2 feet long is heated to redness, and laid across the anvil or fixed by its cold end in the vice. The work is placed on that part of the heated surface of suitable temperature, gradually sliding the work towards the heated extremity.

The correction of distortions is effected by means of the hammer at the period of letting down; and this should be done upon the anvil with the thin pane of an ordinary hammer. The blows are delivered on the hollow side of the work at right angles to the length of the curve, thus the concave side is gradually elongated, and the plane surface gained. We will return again to this matter.

COOK'S RIVETTING MACHINES.—Messrs. D. Cook and Company, Engineers, Glasgow, sent away last week three of their patent steam rivetting machines, one of them for a marine engineering firm in Bremen, and two of them to the order of a large engineering firm in London. These machines are made when required to punch, shear, and rivet; they are made to rivet either horizontally or vertically, and are well adapted for girders and cylindrical or square boilers.

ON THE ENGINEER'S SLIDE RULE.

(Continued from page 104.)

I am now in a position to explain more fully the difficulty generally experienced in reading off the numbers obtained by the different processes.

It must be borne in mind when dealing with the numbers marked on the rule that although they are arbitrary and hence for the time being we can call them what we like, yet we cannot positively alter their true values, but must always account for the assumed values in the results we obtain; thus, if we call 2, twenty, and multiply by it, our result will be ten times too much, and therefore in valuing such a product we must always remember to omit the terminal cypher. On the contrary, if we have to multiply by 20, and only really take twice the quantity, our result is evidently ten times too small, and hence we must not omit to add a cypher to our results. This borne in mind, suppose on our rule we had to multiply 25 by 35, we should take 2 and 5 of the long divisions on A, and call them 25 (while in reality they are only 2.5), and setting this point against 1 on B, then finding 3 on B, and calling it 30, with five of its longest divisions we call that 35 (though really 3.5), and against this number on A, we find 8 and $\frac{7}{8}$ divisions, which expressed in numbers is 8.75, and to value this number we must bear in mind that in both multiplier and multiplicand we divided by 10, hence in the result we must account for that suppression, by again multiplying by two powers of 10, that is 100, making the product instead of 8.75 equal to 875. This operation, simple as it may appear, is a great one, in fact, the chief difficulty in the way of a beginner, but like all other obstacles it can be got over by perseverance.

As previously stated, multiplication and division form the basis of all calculation, and the first instance in which they are used in their combined form is in what is termed "proportion" or the "rule of three," and as in multiplication and division the lines A and B only are used, so also in this combination the same lines answer all questions.

In this rule three numbers are given to find a fourth, and it will always be found that two of the given numbers are alike in kind, the remaining one being of the same kind as the one sought for, this single term must be found upon the line A, then we consider whether under the given conditions the answer should be more or less than this unpaired term, if more, we set the least of the paired terms under it on B, and the answer will appear against the greater on A, but if the answer must be less, we set the greater of the paired terms on B against the odd term on A, and against the lesser term on B will be found the answer on A.

Hence we see that the odd term and the answer always appear on A, while the paired terms must be found on B, and by duly considering the parts these terms play in the operation, and assigning to each its proper place, the rule of three, whether direct or indirect, is performed by the same operation without requiring us to reverse the slide (as is usually taught) making a distinction where no absolute difference exists.

As an example, suppose 7lbs of iron cost 11d., what would 28lbs. cost? Here we have 7lbs. and 28lbs. both alike in kind, and an odd term 11 pence, which will be of the same kind as the answer, consequently we take 11 on A, and we see at a glance that 28lbs. of any material will cost more than 7lbs., hence we place the 11 on A against the least term 7 on B, and opposite the remaining term 28 on B, we find 44 on A, the price in pence of the 28lbs. of iron. Again, if 4 men can do a piece of work in six days, how long should 8 men be doing the same work?

Here 6 days is the odd term to be found on A, and it is evident that 8 men could do the work in less time than the 4 men, hence we place the 6 on A against the greater term 8 on B, and against the other term 4 on B, we find 3 on A the answer sought.

The next step forward is "the square and its root." The square of a number is the product of such number multiplied by itself, thus $4 \times 4 = 16$; here 16 is the square of 4, and 4 is the square root of 16.

Now in all cases where the square of a number is concerned, the index of its power is 2, hence the logarithm of any number being multiplied by 2 gives the logarithm of the square of that number, and if we examine the lines C and D on our rule, we find as before stated that all the divisions on D are exactly twice as long as those upon C, consequently if we find any number upon D, its square will appear upon C, and *vice versa* if we take any number upon C, its square root will appear upon D.

* Contributed by Mr. W. Tonkes.

and it is for this reason that the line D is divided as a single radius while the other three are made double.

The principal use to which the square and its root is applied, as connected with the slide rule is to find a mean proportional between two given numbers, or to find the side of a square that shall contain the same number of units of measure as any given parallelogram.

Thus supposing we had a plate of iron 8 inches long, and 2 inches wide, its superficies would be 16 inches, now we want to find the side of a square that would contain exactly the same number of inches in area, and that will be the mean proportional.

To do this on the slide rule we set the 2 on C, to the same number 2 on D, and against 8 on C is 4 on D, the number sought for, if we multiply 4 by 4 it gives 16 inches, the same area as the parallelogram 8 inches by 2 inches.

The next step onward treats of "the cube and its root." The cube of a number is its product when multiplied twice into itself, thus $4 \times 4 \times 4 = 64$ the cube of 4.

To find the cube of a number on the slide rule we set the given number on C to 10, and against the given number on D is the cube on C; but in finding the cube root of a number our slide rule to a certain extent fails in that simplicity and certitude which characterize all its other operations.

The method is this, we invert the slide, bringing the line B against D, then setting the given cube number on B against 10 on D, we look along the rule till we find a number on B exactly coinciding with a like number on D, such number will be the root sought, but it is evident that unless the root is an whole number, considerable difficulty will be experienced in finding the correct root among the minor divisions, especially as they have to be estimated backwards in consequence of the slide being inverted. It must, however, be remembered that from the nature of its construction the slide rule was only designed to deal directly with involution or evolution, so far as the second power or square was involved, and the fact that we can by any means adapt it to do more than that for which it was designed is only another striking proof of the immense versatility of its powers as a calculating machine.

I now come to the application of the foregoing rules to the various purposes in which they become useful to the mechanic. The lower leg of the slide rule is covered with a great number of figures together with a collection of hieroglyphic F's and I's and sundry other abbreviations, the whole being generally described as a table of "gauge points," but in no work that I have yet seen can I find a lucid description of "how" these gauge points are obtained, or "why" they should be used in the manner described in the rule books generally published, and since at least half the value and the whole interest of mathematical enquiry is lost when the aspiring pupil is deprived of the *why* and *wherefore* of his operations. I will endeavour to show briefly as possible whence these mysterious "gauge points" are derived, and then proceed to a few instances of their application.

(To be continued.)

THE ENGLISH MECHANIC.—HIS RISE AND PROGRESS.*

The subject I have chosen for my brief paper may seem a rather egotistical one, for I mean to speak of ourselves, and of our own and kindred institutions. Possibly I may be excused for my temerity, even by those who have not always shown themselves favourable to this Association, and who, indeed, have orally, and in print, endeavoured to depreciate it in the eyes of the scientific public. It happens that I stand in a position apart from the circumstances which surround most of my brother members, and am, therefore, enabled, I think, to speak dispassionately, and without bias, of the progress, prospects, and usefulness, or otherwise, of this society. My long and intimate connexion with it enables me also to advance my opinions with the confidence which results from experience, although not, it is to be hoped, in any dictatorial spirit. I may say at once, then, that in my mind there is no doubt as to the usefulness and value of such associations as our own, not only to the class of men who are eligible for membership, but to the classes which are immediately above and immediately below that class—employers and workmen—as well as to the general community.

In order to demonstrate the grounds upon which I justify "the faith which is in me" on this point, and

to fortify myself for its defence, it will be necessary for me to glance at the history of mechanical engineering in this country during the past half century, and to endeavour to assign to the foreman engineer his true position in regard to it. It is not needful to expatiate upon the wondrous mechanical triumphs which have been achieved during the period named. They are patent, not only to those who have shared in effecting them, but to the public who have partaken largely of the advantages resulting from them, and who every day find life made more and more enjoyable through their existence. When the advancement made of late years in the invention and construction of labour-saving machinery is taken into account, when the locomotive is found puffing its rapid way across rivers, through tunnels, over mountain gorges, and in fact defying geological eccentricities, and the obstacles which nature appears to have provided only in order that man's God-given skill and industry may remove them; when the noisy paddle or the noiseless screw is seen propelling that marine locomotive—the steam-boat—in the teeth of the most violent gale, and over the most stormy sea, and carrying its living freight, and its dead stock of merchandise almost from pole to pole, in safety; when the sharp click of the sewing machine is heard in the cottage, and one knows that it is ministering to the moral and the physical good of its attendant, as well as to the comfort and convenience of all; when these and a hundred other mechanical glories which might be enumerated are considered, I say that the engineer and the artisan may well congratulate themselves, and, without self-pride, thank God that they have been privileged to assist in effecting them. "He's only a mechanic," is an expression sometimes used in disparagement of the man who weeps in, week out, pursues his modest calling, and who eats no bread but that which he has toilingly earned. Only a mechanic! why, where would England be at this moment but for its mechanics, past and present? It is not necessary to summon up as witnesses in favour of the mechanical class the spirits of Watt, of Rennie, of Neilson, of Bramah, of Huntsman, of Maudslay, or of other giants who have passed away, for we have among us now worthy followers of those illustrious men, whose names are known to you all, and who are creating for themselves niches in the gallery of fame beside those of their predecessors. Only a mechanic! I can say for myself that I rejoice in being a non-commissioned officer in the ranks of the mechanical army of Great Britain, and in having been permitted to share—however humble the duties entrusted to me may have been—in the great work of improvement and of civilization in which it is constantly engaged.

I predict that the time is not far distant when the mechanic shall receive fuller and more honourable acknowledgment than he has ever yet obtained; when those who enjoy privileges, and comforts, and advantages inestimable, which are traceable directly to his agency, shall at least admit his merits, and no longer taunt him with presumed inferiority.

In effecting those vast onward strides in every branch of mechanical industry which have been made in England since the dawning of the present century, it is easy to discover the fact, that the impetus has been derived not alone from the action of the few, but the combined influence of the many. I venture to say that there is scarcely an invention of an engineering nature in practical use at present which owes its existence to any one man. It is possible that the idea of a contrivance for accomplishing a certain purpose may have been the production of one fertile brain, but in its realization, in the perfecting of details, in the surmounting of practical difficulties, in short, in the *working out* of the scheme ninety-nine times in the hundred the inventor is indebted to others for suggestions, and even more tangible assistance. It is not for me to detract from the merits of those remarkable men who stand out prominently, who shine as "bright particular stars" in the mechanical orriment, and cast a portion of their lustre on their fellows, but it must be permitted me to say that some portion of their light, like that of the moon, is borrowed.

To their assistants of each grade they owe something; and although those assistants may not be fortunate enough to find a *Smiles* for a biographer, and may die "unwept, unhonoured, and unsung," yet have they been useful to their employers, and in their generation, and their claims to acknowledgment cannot be ignored. It is not long since, on a very happy occasion, when certain clouds, which for a time overshadowed us, were not visible, and which clouds have now dispersed—it is not long since that Mr. Penn stated that "a good foreman engineer was the *right hand* of his employer." My own knowledge of the profession, and my acquaintanceship with numerous representatives of both the classes named

by our excellent and generous friend, enables me to state that in making the remark he spoke what is emphatically the truth. I go further, however, and say that the foreman engineer not unfrequently constitutes a portion of a more important organ of his employer's body than the hand—namely, the head. Let it not be understood for a single moment that I say this offensively; I have no such intention—far, very far from that. It is merely by way of an extension of Mr. Penn's simile that I venture upon the remark. The foreman engineer, I wish to show, has to think as well as to act. He must not only have used his hands but his mind to some purpose, or he would not have obtained the dignity attaching to his post. There is no royal road to foremanship with which I am acquainted. The heights of office must be reached by the use of mental scaling ladders, and by industrious climbing; and they are only to be retained possession of by constant watchfulness and unwearying exertion. No foreman engineer with whom I am acquainted ever received his appointment from mere favour. It is true there is no Dean's-yard Council sitting, in a torture chamber, for the purpose of testing his knowledge of matters which it is unnecessary for him to have learnt; but before being admitted to his office, the foreman engineer is invariably put through a far more efficient ordeal. He must have displayed a sound practical acquaintance with his art, he must have proved himself a good workman in the various branches of his profession, he must be a draughtsman, possess commercial abilities, and understand thoroughly the nature, characteristics, and cost of the materials to be used under his direction. Beyond and above these qualifications, the candidate for foremanship in an engineering establishment must comprehend the scientific theory upon which all engines and all machinery are based, the laws of nature which govern their action, and, in addition, he must understand *human character*, so as to control with temperate firmness and discretion the workmen who are to be placed under his direction. And these are only a portion of the requirements of a foreman engineer; and no doubt many who are listening to me now could draw from the varied notes of their own experience many more illustrations of his necessities supplementary to my own.

Now, it is in the *workshop* that the would-be foreman must acquire and exhibit the talent which is to warrant and justify his promotion. That is the university in which he must graduate, and in which he must earn his degrees. In the workshop he must obtain his honours, and there he must develop his latent powers. No *examining process* will enable him to avoid the *plucking* which sometimes befalls candidates for the Civil Service, or sustain him under the pressure of constantly changing duty. It is only by the plodding and persistent pursuit of information, and the determination to surmount difficulties, that he may hope to rise, or to sustain himself when he has risen, from the ranks of his fellow-workmen.

If I rightly understand the principles of this Association, and of those kindred institutions of foremen engineers which have happily come in to existence, and which are flourishing, I am glad to say, in Manchester and Leeds.

(To be continued.)

STEAM AND CANVAS.—A New York paper speaks of the remarkable decline of sailing power and advance of steam power on the ocean as evinced by the fact that on one day twenty steamships left that port—two of them for Europe and eighteen for the Southern ports, to aid in the work of reconstruction. It is an evidence, also, of the way in which that country adapts itself to circumstances. Its sailing marine was becoming almost cumbersome. It had not dock and pier room enough to accommodate it; but as one steamship can do more carrying trade than a dozen sailing vessels, in consequence of the rapidity and regularity with which it traverses the ocean, the latter will gradually vanish, and the United States be able to do all the carrying trade they require with half the accommodation at the piers and docks.

SMEETING ZINC ORES.—The invention provisionally specified by Mr. A. Reynolds, of Bagillt, consists in the arrangement of a furnace (such as a blast-furnace) with a flue or condenser, in such a manner that zinc can be smelted in it instead of in retorts. The zinc passes off in vapour with the smoke at the top of the blast-furnace, and in order to retain the zinc in the metallic form air must be carefully excluded from the top of the furnace, or preferably coke must be placed in the flue, or charcoal may be employed instead; the coke will be heated by the smoke, or may be heated otherwise, so as to reduce the zinc to the metallic form. The zinc from the smoke is subsequently condensed in suitable chambers.

* A paper read by Mr. Joseph Newton before the London Association of Foremen Engineers, November 4th, 1865.

BORING, DRILLING, &c.

(Concluded from page 91.)

MANY works, from their weight or size, cannot be drilled in the lathe in its usual position, as it is scarce possible to support them against the drill, but such are readily pierced in the drilling machine, which may be looked upon as a lathe with a vertical mandril, with the flange of the poppet-head enlarged, with a table for the work, which is only occasionally fixed thereon. The structure of these machines admits of that endless diversity which is observable in manufactories, but probably no individual originated more useful varieties than did the late Mr. Richard Roberts, of the Atlas Works, Manchester. Figs. 1 and 2—Nasmyth's Portable Hand-drill—are simple examples of drilling machines. The spindle, as shown, is driven by a pair of bevel pinions—the one attached to the axis of the fly-wheel, the other to the drill shaft. Sometimes the drilling spindle revolves without end-long motion, and the table is raised by a treadle or by a hand lever; mostly, the drill shaft is cylindrical, and revolves in and slides through fixed cylindrical bearings. The drill spindle is then depressed, sometimes by a simple lever, at others by a treadle which either lowers the shaft only one sweep, or by a ratchet that brings it down by several small successive steps through a greater distance; and mostly a counterpoise weight returns the parts to their first position when the foot is removed. And so on.

Drilling machines of these kinds are generally used with ordinary drills, sometimes with pin drills; the latter appearing to be a type of the cutter bars used for larger holes, or holes of superior accuracy than can be got from the ordinary pointed drills. The small application of cutter bars is shown in fig. 3. The cutter *c* is placed in a mortise in a cylindrical boring bar, and is fixed by a wedge; this cutter extends equally on both sides, and the ears embrace both sides of the bar, which is slightly flattened near the mortices. Cutter bars of the same kind are sometimes employed with various forms of cutters, for grooves, mouldings, &c., and even screws on parts of heavy ordnance, and those which cannot readily be fixed in the lathe. Fig. 4 represents one of these, and the larger application of the principle as shown in fig. 5, where a cast iron cutter block is keyed on a cylindrical bar; the block has four or more grooves in the periphery. Sometimes the work is done with only one cutter, and should the bar vibrate, the other grooves are filled up with pieces of wood to complete the bearing; occasionally cutters are placed in all the grooves, and carefully adjusted to act in succession—the first standing a little nearer to the axis than the second, and so on; but the last takes only a light finishing cut, to preserve its keen edge. It should be observed that in these cutters the one face is radial, the other differs only 4° or 5° from the right angle, and the corners of the tools are slightly rounded. The application of these cutter bars, though various, resolve themselves into three principal modes:—1st. It revolves without end-long motion in fixed centres, as a spindle in a lathe; the work is made to pass the cutter in a right line, and for this the work is often fixed to a traversing slide rest. The cutter bar revolves and also slides with end-long motion, the work being at rest. The bearings of the bar are then frequently attached temporarily to the work to be bored, and it may be mentioned that cylinders of forty inches diameter have been thus bored by attaching a cast iron cross to each end of the cylinder; the crosses are bored exactly to fit the boring bar, one of them carrying the driving gear, and the bar is thrust end-long by a screw with a ratchet wheel. Or, in another common arrangement, the boring bar is mounted in headstocks, and the cutter bar advanced

by a screw. The screw is then moved either by hand, by a star or ratchet wheel, or by a system of differential wheels in which the external screw has a wheel of 50 teeth, the internal one of 51 teeth, and a pair of equal pinions drives these screws continually, so that the advance of the 1-50th of a turn of the screw, or their difference, is equally divided over each revolution of the cutter bar. This second method only requires the interval between the fixed bearings of the cutter bar to be as much longer than the work as the length of the cutter block, but the bar must have more than twice the length of the work, and requires to slide through the supports.

This kind of cutter bar is likewise used in the lathe; whilst boring, the end of the bar slides piston-wise into the mandril. Such are applied to the larger kinds of vertical boring machines fitted with a differential apparatus to determine the progress of the cut; the bar then slides through a collar, which is fixed in the bed of the machine. In some of the large boring machines, horizontal slides are added, and, as will be understood, by their aid a series of holes may be bored; thus, the holes in the beams or side levers and cranks of steam engines are bored truly perpendicular in a line, and at any determined distances, by shifting the work beneath the revolving spindle upon the guideway. In other kinds of work the movement is lateral during the revolution of the cutters, for elongated countersinks and grooves

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 6.

FIG. 5.

Lastly. The boring bar, in the largest application of the principle, revolves upon fixed bearings without traversing; and here it is necessary that the boring bar should exceed the length of the work by the thickness of the cutter block, which, by the way, traverses as a slide down a huge boring bar, whose diameter is above 30in.—that of the cutter block being sometimes ten feet. A groove and key couple them together, and the traverse of the block down the bar is caused by the side screw, on the end of which a wheel takes into a small pinion fixed to the pedestal of the machine. With each complete revolution of the cutter bar, this wheel is carried round the fixed pinion; and taking these to be 10 : 1, the wheel is moved a tenth of a turn, and, therefore, moves the screw a tenth of a turn also, and so slowly traverses the cutter block. In fact, this contrivance is a huge self-acting revolving sliding-rest, and the diagram, fig. 6, shows that the cutter bars are as well applicable to portions of circles, such as the D valves of steam engines, as also the interior of the cylinder itself.

Wood shavings are now extensively used for the manufacture of paper. To ascertain whether a given kind of paper contains wood it is dipped in a warm solution of aniline and pure sulphuric acid, when it will be immediately coloured orange if wood be present.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents.]

STEAM BOILERS

Sir,—I am somewhat amused with the opinion and assertions of your correspondent A. Nelson on the subject of steam boilers. He don't appear to be in possession of a very extensive knowledge of the best modes of construction, or the action of heat and water upon the plates. If he will make a tube (welded) truly circular, and insert some welded pipes of a little less substance, in consequence of its smaller diameter, and weld those into his tube diagonally, vertically, or transversely, he will find this method an improvement upon staying by hoops of either angle or T-iron for the tubes will expand and contract equally, which is a great desideratum in the working of a boiler, not only so, but a preventive to collapse, and a great saving in fuel in consequence of increased heating surface. If he is disposed to adopt this method of construction he will find there are some engineers who will not doubt applaud his efforts to improve the means of producing power with an increase of pressure at a decrease of danger, or risk. The process of welding boilers or tubes is simple, as also of welding one into the other, and if he or your correspondent Aspinall can take a journey to the Masbro' Boiler Works, I shall take pleasure in showing them how it is done.

ROBERT JENKINS.

Masbro Boiler Works, Rotherham, Nov. 23, 1866.

Sir,—In your last number you had an article on Drilling and Boring, than which there is probably no subject of greater interest to the mechanic.

In this article it is stated that, "As the cylinder bit is not intended to be used in drilling holes in the solid material, the following course should be adopted," &c. It is a misconception—a very popular one, I grant—to suppose that the cylinder bit is unsuited for drilling a hole out of the solid; so far from that being the case, it is the very best instrument that can be used for the purpose.

The recentering drills (your Fig. 6) is altogether useless, so also is the piercing drill (Fig. 5) after the cylinder bit is entered.

So great is my faith in this kind of drill that I would undertake with it

to bore a 1-inch hole through a shaft 30 feet long.

Some time ago I had occasion to drill one hundred holes, through as many pieces of wrought-iron 8 inches long, 7 inches had a hole of $\frac{3}{4}$ in diameter, the remaining 1 inch had a hole $\frac{1}{2}$ in diameter. I drilled twenty of these in a day, of less than ten hours. I may remark that each piece was centered, and the ends turned in the lathe, one end was then held true by the chuck plate, the other revolved in a bearing; the holes were drilled by the cylinder bit, and when the end of the small bit came out at the end it forced out a very thin disc of the metal. In nine out of ten the centre mark

upon which the iron was turned was exactly in the centre of this disc.

Probably many of your readers have done even better than this, so there is no doubt other of your readers besides myself would be interested in hearing of their practice, and I dare say you will afford them the necessary space in THE ENGLISH MECHANIC.

W. H. NORTHCOOT.

Sir,—Doubtless you were not aware when you published in your paper of the 13th ultimo a method of generating steam power by gas heat that I was the patentee. As your notices and drawings may be calculated to lead parties to the belief that this method can be used otherwise than through my license, it is only right that I should inform you of the fact, and also inform you that either my manufacturing agent, Mr. Thos. Middleton, of 1, 2, and 3, Loman-street, Southwark, or myself will be happy to give you or any one interested all particulars and information on the subject.

I think it is only due to your readers and myself that you make this known through the same medium.

ARTHUR JACKSON.

Patentee, 25, Delamere-crescent, Bayswater.
No. of Patent, 2047, 1860.

OVAL AND ECCENTRIC CHUCK.

Sir,—I was as much surprised as pleased by Mr. Muir's drawing and description of the above; for, a few years ago, having failed in an attempt to make a slide-rest, I adapted the materials to a similar purpose. The result is so exceedingly similar to Mr. Muir's chuck, with what I consider greater facility of change from oval to eccentric, and vice versa, and the whole at so moderate an expense, that I am

tempted to send you a diagram. The cost to me was much under 10s., for I employed flat bar wrought iron, and rolled brass, so saving the expense and delay of patterns and castings. My own labour goes for nothing, and the proportion of wear and tear of tools for very little. My chuck works satisfactorily, and I think that one similar, or better, is within the ability of any amateur turner.

Fig. 1. Arrangement of chuck for oval turning. The screws are left on the slide for safe custody, and when placed as in the figure, allow the front plate to traverse freely along the slide. The fly nuts on the shanks of the screws allow of their ready removal from the slide, or of their adjustment at any angle.

Fig. 2 shows the front plate arranged for eccentric turning. The screws placed parallel to the slide adjust, and fix the front plate at any part of the slide as in ordinary eccentric chucks but more steadily; for, as the screws act against each other, there should be no shake.

Fig. 3 is an enlarged view of one of the adjusting screws. These can be placed nearer to the centre by means of drill holes in the iron slide.

CHEMICO.

OUR SUBSCRIBERS' NOTES AND QUERIES.

COIGNARD'S PUMPS.—Can any subscriber inform me where I can see one of Coignard's centrifugal pumps at work?—G. F. SUFFOLK.

CONDENSER.—Can any reader inform me how to make and connect a tinfoil condenser to an electro-magnet for giving shocks? Also state the price per square foot (not weight) of tinfoil, and where it is to be had, not being not being able to get it in Halifax, where I reside.—A. H. V.

CONDENSERS.—Any of your subscribers would favour me very much by informing me how the tinfoil condenser is fastened to the contact breaker—whether soldered or otherwise, or if it is fastened both to the upright with the pointed screw, and to the spring, and where the joint is made?—WM. GIBSON.

STEAM WHISTLE.—Will any of your numerous readers give a drawing of a steam whistle, such as used on locomotives, showing how the top part is attached to the lower cup giving the steam passage?—HENRY WILLIAMS.

DRAWINGS.—Can any of your readers inform me of the best method of making shaded and coloured drawings upon the patent tracing cloth.—A. YOUNG DRAUGHTSMAN.

EXPANSION SLIDE.—Will any of your correspondents be good enough to inform me how I can determine the proper amount of travel for the expansion slide in Meyer's arrangement (when two blocks are used on a spindle having right and left-handed screws), also the position of eccentric in relation to the crank to cut off at any given point? I mean the eccentric of the expansion of the blocks, the position of the main eccentric being already determined.—EXPANSION.

WINDMILL.—I want to make a windmill to cut chaff, or pump water. Can any reader direct me how to construct one cheaply? A strong boy can do all that I should require of the mill.—GEO. B.

SHEET INDIA-RUBBER.—I wish to purchase a quantity of India-rubber in thin sheets. I have tried gutta-percha, but it did not suit my purpose. Can any of your readers tell me where to purchase the India-rubber?—O. G.

MAGNET.—Will any reader kindly inform me if there is any substance which, if placed between a magnet, and an object influenced by its attractive power, will destroy (either wholly or partially), the influence of the magnet on such object?—F. R. S. A.

BROWN, EXAMINING, &c.—Can any of your readers give me the following information:—

1st. Where I can get a book or other reliable information relating to the most improved method of the mixing and management of brass, bronze, and other alloyed metals. Or can you give a recipe for cheap machinery bearings, and brass for common purposes.

2nd. Can you supply me with a receipt for enamelling cast-iron on a cheaper method than is usually done. The common enamelling is excessively dear, and cannot be done nearer to Glasgow than London, which is a great drawback to its usefulness?—A. FERRIER.

RUST ON GUNS.—Can any of your readers inform me how to preserve guns, revolvers, &c., from rusting without using oil or grease, thinking these might be a kind of varnish useful for that purpose, and where it is sold?—D. V. L. C.

COUPLING MOTIVE POWER.—I know a factory where they have two beam engines coupled. They are over-weighted. They are about to connect two oscillating engines to the same cranks. The steam first to the oscillating high pressure engines, and then to the condenser engines. I think if both had the steam direct, they would be of greater benefit. I shall be thankful if you or your correspondents will give me their opinion.—D. D. B.

CRANK AND GUIDE BARS.—Will you permit me, through your valuable journal to ask some of your numerous correspondent two or three queries in relation to the crank and guide bars.

Enclosed is a diagram which I have made. I will first explain the construction, and then give my queries:—W, W, is a vertical line passing through the centres of the cylinder and crank shaft; O is a circle, the diameter of which is equal to the stroke of the piston, and the circumference is the path of the crank pin.

The lines Xa, Xb, Xc, Xd, are the centre lines of the connecting rods at the different angles found at the corresponding part of the stroke as marked on the vertical line W, W.

The lines A (at the centre) to 1, 2, 3, 4, are the different centre lines leading through the crank and crank pin formed at the different portions of the stroke marked on W, W, and in connection with the connecting rod.

The lines 1-b, 2-b, 3-b, 4-b, are at right angles with the lines A, 1, 2, 3, 4, 2, b is made the full length of the stroke 2-b less 3, b less 4, b less, and so on. The lines 1-b, 2-b, 3-b, 4-b are at right angles to 1-b, 2-b, 3-b, and 4-b, and they are parallel with the lines A, 1, 2, 3, and 4, and are made to intersect the connecting rod centres and b respectively.

Guide or Motion Bars.—The lines a1, a2, a3, and a4, are all the same length—that is, uniting each at their lower extremity intersect the connecting rod lines, each meeting the corresponding one at that particular portion of the stroke.

The lines 8-a1, 8-a2, 8-a3, 8-a4, are lines drawn at right angles to intersecting the lines a1, a2, a3, and a4. I think I have made the above as intelligible as possible, and have no doubt that it will be readily understood. Now for the utility and the queries first. The crank first.

The lines 1-b, 2-b, 3-b, 4-b, are the effective valves of the crank. Does this relate to the length of stroke or the pressure on the piston? I understand it is thus:—Take the line 3-b, marked 3, that is, 3 of the stroke, therefore the pressure on the piston, multiplied by 3 of the

stroke is the effective value at that particular portion of the stroke, or portion of the crank pin path.

2nd. The lines 1-b, 2-b, 3-b, 4-b, is the strain or pressure, or the crank pin to obtain the effective value of the crank. I understand it thus:—Take the line 1-b, and suppose it to be 1 of the length of the stroke, then the pressure on the piston, multiplied by 1 of the stroke is the pressure on the crank pin, which gives and acts as a lever to obtain the effective value 1.

Query 3. To obtain the strain on the guide bars. The lines 1-a1, 2-a2, 3-a3, 4-a4, represents the strain or pressure due to the angle of the connecting rod.

I understand it thus:—Suppose, for brevity, that the line 1-a2 equalled 1 of the length of the stroke, the pressure on the piston multiplied by the length of stroke, and 1 of the product is the strain required.

I shall be very glad to receive any information on the subject that your correspondents can give.—WILLIAM COOPER.

TELESCOPES.—If your correspondent, E. B. P., has ever looked through a prism, or one of the triangular stalks of glass which hang from the old-fashioned "lustras," and seen the brilliant colours with which it fringes every object, he will easily understand why a telescope with a simple convex lens for an object glass will not bear any amount of magnifying power. A section of such a lens at right angles to its diameter, as at A B, in the figure, really represents two such prisms base to base. If C D, be an object

Illuminated by white light, a violet image of it will be formed at V, a red one at R, and intermediately, blue, green, yellow, and orange ones. Of course, at no distance from the lens will all these rays come to an exact focus, and this primary indistinctness when magnified to any extent becomes perfectly intolerable. In an achromatic telescope, on the other hand, where all colour is destroyed by the interposition of a second flint lens, reversing the order of the fringes, and where the image is virtually colourless, you may go on magnifying this image until it becomes obscure from loss of light, without materially impairing its sharpness. This explanation may also serve to show Athelstane why no telescope fit to look through can be made without an achromatic object glass. It is perfectly true that some few astronomical discoveries were made by the aid of simple lenses; but then, Athelstane must remember that some of them were of 120 feet focal length, were used without tubes in the most horribly awkward manner; and moreover, that they cost a good deal more than four shillings (or even two pounds ten) to make. With regard to Magnifier's query: It will be much better for him to buy, either a reconnoiterer telescope of Salmor and Co., Princess-street, Edinburgh, (£10 10s., sent free), a "Dyer" telescope, sold by E. G. Wood, Cheapside, London, price, I think, 10s. 6d.; or even a second-hand instrument of Baker, of High Holborn, London, than to try to make one, (in which he will fall disastrously for 12s. 6d.; Chance and Co., of Birmingham, are the only optical glass manufacturers.—A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.

P.S. In the letter which you honoured me by inserting in No. 35, in line 21, the word printed "ellipsoid" should be "ellipsoid" and in line 23, the words "best represents," should be followed by existing measurements.

ELECTRICITY.—In reply to your correspondent, Henry Gornell, in your No. 32. His plan for collecting electricity with 2 rolls of caoutchouc rolled up with 2 pieces of tinfoil, would not, I think, be found to answer. It must be proved that electricity dwells only on the surface of a conductor. Take a small tin cup, and fill it with brass chain, and fasten one end of it to a piece of silk thread, also connect a pair of pith balls with the cup. Place the whole on an insulated stand and charge it from a machine. The pith balls will diverge; now lift, by means of the silk, 10 or 12 inches of chain out of the cup, and the balls will then collapse, but will reopen when the chain is again lowered into the cup; proving that as the surface of the conductor is increased, so the electricity is diffused over it, and of course diminishing in power when more widely spread, therefore causing the balls to collapse; thus showing the fluid is not contained in the chain so long as it remains inside the cup, except at the top surface. Now, it having been proved that a large interior surface is quite useless as a conductor; it is easy to perceive that the inner rolls of your correspondent's arrangement would be needless, as they would, comparatively speaking, be without conducting power, and the outer roll only would be of service, thus the plan would reduce itself to an ordinary jar—a non-conductor covered inside and out with a conductor. The rolls of tinfoil and caoutchouc would, in fact, form a number of Leyden jars placed inside each other; with the interiors connected, also the exterior surfaces; in this plan the external jar only would contain the charge, the inner ones being useless. In an electric battery the jars are placed side by side to give more external surface; if they were put inside each other, no power beyond the outside jar would be gained, as above explained.—CROLYERS.

TELESCOPES.—In reply to Athelstane, in No. 35 of your valuable journal. He can make an astronomical telescope to magnify about 36 times; for which the lenses will cost only three shillings and sixpence, or double that power, six shillings and sixpence.

The answer to E. B. P.'s query is that common lenses will not bear so high a magnifying power as achromatic lenses on account of distortion of the image by the common lens under high powers.

Magnifier. A telescope does not magnify, but brings the object nearer to the eye and consequently it appears magnified.—B. B. Wagon.

LATHE.—In answer to J. W. K., he may find this lathe suit his purpose. It is made as in fig. 1. On the end of the spindle there is a screw which goes into the mandrels, which hold the article to be turned. These mandrels screw up against the collar *b*, which is from 2 to 3 inches in diam.; *c* is the bobbin round which the cord passes from the wheel, the spindle ought to be about 19" long, divided thus: the screw *y* 3" long, from *y* to the groove *x*, 7½" long, including screw, the bobbin *e* 3", and the pulley *f* 1". From *c* to the collar *b* 4", and the collar *b* ½" thick, the screw *a* to be 1" in length. The spindle is made so long, in order that it can slide backwards and forwards; this sliding motion is necessary for making screws and twisted columns.

When the spindle is wanted to stay in its place without sliding, a key (see fig. 3) is placed at the left side, fig. 1 *x*, this key is hung on a pivot so that when the spindle is to be kept from sliding, the end of it is lifted, and the round edge *a* (fig. 3) fits into the groove *x*, that is turned in the spindle. I have already said that the sliding motion back and front is for making screws of different inclination of threads. To make these kind of screws, there is a piece of wood fastened to the left end of the puppet, fig. 1, *m*. In this piece of hard wood is placed an edge like a knife *n*, which enters into the thread of the screw; if the lathe be turned by a wheel, the *p* dial must be tied down, so as only to allow the wheel to swing partly round and then return. As all screws will not be wanted as that on the end of the spindle, screw on a piece of very hard wood on the end of the spindle, and groove it to the pitch of your intended twist, turn the nut *o* on after your wood is in its place,

FIG. 1.

FIG. 3.

FIG. 2.

Fig. 2 is the right puppet, it consists of a block of wood with a disk screwed from the back, in the disk there is bored different sized holes to take the different sized columns, the disc revolves on its centre; the circle of holes to be the height of left puppet.—J. H.

INDIAN INK.—A Draughtsman can make a good Indian ink in the following manner:—Dissolve horn strip with caustic alkali root till it is melted. The brown liquid you get is to be boiled in an iron kettle, until it is as thick as paste. Then pour on it boiling water (double its weight), and precipitate it with dissolved alum. Then dry it, grind it, mix it with gum water, and pour it in a mould. This is recommended by Mr. Boswen, a celebrated chemist.—PHILIP.

A CHEAP STAND FOR A 30 OR 36 INCH TELESCOPE.—Referring to Mr. Wegg's communication on cheap telescopes, I beg to give your readers the following hints, as regards making a stand for it. First I get a piece of beech wood turned to 9 inches diameter, and 3 inches deep, for a foot; next a pillar of brass or tin tube, (mine is a brass tube out of an old telescope) 9 inches long, and 1½ inch diameter, with a flange at the bottom, so that it can be screwed on to the beech with ordinary joiner's screws; then a double jointed gas fitting of the size made to receive a half-inch pipe, is soldered to the top of the pillar. Next I get a piece of tin 5 inches one way, and as much the other as will overlap (say ½ths of an inch) that part of the telescope in which the telescopes would balance, the centre of which may be

found near enough by pointing it upon the fingers; loops must now be formed of the portion of tin overlapping, one at each end on one side, and one in the middle on the other. Each loop to be ¼ of the length of the tin, and of a diameter to fit the insertion of a wire, which will, if the tin has been nicely fitted blind it to the telescope nice and tight. This cylinder is now to be soldered to the upright joint of the gas fitting, and the stand is complete; not perhaps so handsome, but quite as good as can be expected. I inclose you a sketch, which will perhaps help to illustrate my meaning.

Mr. Slugg's price is 16s.; other prices I know 25s., mine cost me 6s. I should be glad if some of your correspondents would communicate further upon astronomical instruments, such as equatorial movements, &c. Perhaps Mr. Slugg himself will favour us.—ASTRA.

BLANSHARD LATHE.—In reply to Nemo, No. 34, volume II., the Blanchard lathe performs all he requires, cuttine shoe lasts, cricket-bats, gun-stocks, &c. He can see several working at the Enfield rifle manufactory, turning out many hundred rifle stocks weekly.—B. F.

FLY WHEELS &c.—In reply to J. D. E. I think Bourne's formula will give him what he requires, which is as follows: Multiply mean diameter of rim by revolutions per minute and square the product for a divisor. Divide the number of actual horse power of engine by number of strokes per minute, multiply the quotient by 2,760,000, and, divide the product by the divisor as above found. The quotient is the requisite quantity of cast iron in cubic feet to form the rim. With regard to the correctness of G. S.'s safety valve formula I beg to differ, the joint is the fulcrum of the lever, not the valve stem. It would be correct, supposing *A* to be length between weight and joint *b*, distance between valve stem and joint, and *O*, the weight, $\frac{a \times c}{b}$ would then give the correct weight on valve, the lifting pressure would be found by dividing the weight on valve; by the area of the valve in square inches. I take the liberty of correcting the error as it is a very usual one. The following is a table of Whitworth pitches to 1½ in.

Diam of screw	No. of threads to the inch.	Diam of screw	No. of threads to the inch.
3-16	24	1	11
1/8	20	1 1/8	10
5-16	18	1 1/4	9
3/8	16	1 1/2	8
7-16	14	1 3/4	7
1/2 & 9-16	12	1 7/8 & 1 1/2	6

Any further information in my power I shall be glad to furnish to ARROW, if the above is insufficient.—HESPERUS.

Diam. of bolt or screw, &c.	No. of threads to the inch.
1/2 inch	16
7-16	14
1/2 & 9-16	12
1/2 & 11-16	11
1/2 & 13-16	10
1/2 & 15-16	9
1 inch	8
1 1/8 & 1 1/4	7
1 1/2 & 1 3/4	6
1 7/8 & 2	5
2 1/8 & 2 1/2	4

FLY WHEEL.—T. D. E. wishes to know how to calculate the weight and diameter of fly wheels for engines of various sizes. I think the following will answer his purpose:—

H = horse power.

*The scale is extended to 2 inches (ad. lib.)

D = mean diameter in feet.

N = number of revolutions per minute.

P = total average pressure on piston in lbs.

W = weight of rim in cwts.

$$= \frac{P \times S}{45 D}$$

$$\text{or} = \frac{1844 H}{D N}$$

D N

D = stroke $\times 3$ or 4 generally. In corn mills the velocity of the periphery of the fly wheel must exceed the velocity of the periphery of the stones to prevent back wash. Sectional arc of rim in inches = $11.43 W$

Another method:—Diameter = 3 to 5 times stroke of engine. Weight of rim = about 8 cwt. per horse power. Weight in cwts = $11.4 W$

Mean diameter of rim in feet
= Sectional area of rim in square inches.

$$P \times S \times a$$

$$W = \frac{45 D}{P \times S \times a} \text{ where}$$

W = weight of rim in cwts.

D = diam of wheel in feet.

S = stroke in feet

A = area of cylinder in inches.

If a light wheel is required use 60 instead of 45. If a heavy one use 80. This rule gives to the fly-wheel 3 to 6 times the average momentum of the piston. I also send a table of Whitworth's screws for Arrow, from 3-16 to 6 in.

Diam. in inches.	No. of threads to the inch.	Diam. in inches.	No. of threads to the inch.
3-16	24	2	4 1/2
1/8	20	2 1/4	4
5-16	18	2 1/2	4
3/8	16	2 3/4	3 1/2
7-16	14	3	3 1/2
1/2	12	3 1/4	3 1/2
5/8	11	3 1/2	3 1/2
3/4	10	3 3/4	3
7/8	9	4	3
1 inch	8	4 1/4	2 1/2
1 1/8	7	4 1/2	2 1/2
1 1/4	7	4 3/4	2 1/2
1 1/2	6	5	2 1/2
1 3/4	6	5 1/4	2 1/2
1 7/8	5	5 1/2	2 1/2
2	5	5 3/4	2 1/2
2 1/8	4 1/2	6	2 1/2

Excuse me for taking up so much of your valuable space. —JAMES MORRISON.

PRESSURE IN BOILERS.—In your impression of the 17th inst. G. S. appears to be incorrect. 1st. He does not take into consideration the action of the weight of the lever and weight of valve, both being part of pressure on *d*. 2nd. G.

$\frac{a \times c}{b}$ = total weight on *d*.

Let *a* = length between weight and valve spindle.

b = do. valve spindle and standard.

c = the weight in lbs.

E = action of weight of lever and weight of valve in lbs.

According to the principle of the safety valve lever:

$$\frac{a \times c}{b} = \frac{E}{b} \text{ resistance at standard.}$$

It is evident then, that $\frac{a \times c}{b} \times c \times v = \text{total weight on } d$, which gives the five following theorems for each quantity.

$$\frac{a \times c}{b} \times c \times v = d \dots (1)$$

$$d - c \left(\frac{a \times b}{b} \right) = e \dots (2)$$

$$\frac{b(d - e)}{a \times b} = c \dots (3)$$

$$b(d - e - c) = a \dots (4)$$

$$\frac{c \times a}{d - c - e} = b \dots (5)$$

J. S.

A COMMITTEE will shortly be appointed to experiment upon coal-cutting machines.

THE HEIGHT OF A SECTION OF THE GLOBE.—If it were possible to separate the globe at its centre, in the same way as an orange or cheese is frequently divided, and to stand at the base of the division, the chasm would represent a height 1,456 times higher than the Himalayas, or if Great Britain were reared on end from the Solent to Cape Wrath, it would reach but about one-twelfth of the distance.

THE SOHO WORKS, BOLTON-LE-MOORS.

From the Engineer.

(Concluded from page 105.)

The greater number worked very well, but one or two out of the lot got each day out of order. The result was that the man usually employed to perambulate the works and lubricate the shafting, had to continue at least a supervision over the bearings, so that little or nothing was gained by the numerous lubricating apparatus. They were afterwards removed, with a return to the old system of hand lubrication, with its attendant objections, amongst others, of much waste of lubricating matter. The *sine qua non* of an apparatus of the kind is thus simplicity, which seems to be attained in the plan. At the two ends of the shaft, and at right angles to the axis of the shaft, are two recesses extending all round the journal. In the bottom half is the oil. In one of the recesses is a small ring, formed of round wire, sprung together with a tongue joint. We understand that a grooved bearing oiled in this way can be left to itself for more than a quarter of a year.

Thousands of men and boys are being every day let up and down the colliery pits of this country by means of wire ropes. It is only long habit that can quite overcome the rather uncomfortable feeling that one's life is literally dependent on a thread—of iron or steel though it be. In some mining countries, such as those of Germany and Austria, it is forbidden by law to use mining cages unprovided with safety apparatus for raising and lowering the miners. Much damage and loss of life are annually caused in this country from the mining cages being but seldom provided with one or other of the several forms of safety apparatus which have proved themselves to be more or less efficient. A rather large number of contrivances of the kind were to be seen at South Kensington in 1862; some of them very ingenious, and constructed on sound principles; others scarcely deserving such praise. We remember a very eccentric cage of the kind. It was so designed as to bring catches against the pit guides by means of the action of a common ball governor; and it was expected by the inventor that (supposing the instrument kept up its efficiency in the midst of the pit dirt and coal dust) a too high speed of the balls would be sufficient to cause the catches to act and stop the descending cage. Unfortunately, however, the cage came to grief in the very exhibition itself, as the governor balls refused to act when the cage (which was arranged in guides of some altitude) was allowed to drop by the exhibitor. An evidently much more efficient apparatus of the kind is that of Mr. Owen, made at these works, and several specimens of which have been in efficient action for some years in the Lancashire mining districts. The safety apparatus has also been applied to some of the hoists now getting so much into use in the great hotels and other establishments; and Messrs. Hick have set up one or two in the metropolis. The plan is simple enough, and bears on the face of it a stamp of satisfactory efficiency. The broad principle upon which the safety cage relies for its action when the rope breaks, may be said to consist in employing the weight of the tackle used to attach the rope to the cage to bring the safety catches into operation. Upon each side of the guide rods are two levers, turning on hinges upon forks fixed in the hoist or cage. The longer ends of the lever are jointed to connecting links, attached to a link to which is secured the winding rope. The whole weight of the cage is carried in the pins of the levers, the longer ends of which are also drawn up by the rope, while the shorter ends are also necessarily at the same time kept away from the guide rods. Should the rope break, the links and other parts also fall down, causing the short ends of the levers to catch against the guides, and this action is also quickened by means of springs placed in the long ends of the levers. These springs also in a great measure carry out the important functions of draw-springs between the rope and the cage, preventing those injurious jerks which quickly wear away the rope, more especially at the portion immediately adjacent to the cage. We hold that both safety and economy—generally convertible terms—should always lead to the addition of an elastic attachment between the cage and a wire rope—more especially in pits worked at a quick speed.

In the invention, as applied by Messrs. Hick and Son to a hoist for a mill or similar building, there are stops for the levers to sit against when hoisting; steel springs to force down the levers, and cause their sharp points to dig into the slide in case the rope breaks, a wrought iron cross connecting the levers to a pair on the opposite side of the cage.

To the centre of this cross is attached the rope for lifting.

After having been making so many large stationary engines for such a number of years, being in the centre of the cotton districts, where, especially for driving machines for spinning fine numbers, very regularly working engines are so absolutely required, it was natural that the Bolton firm should direct all its skill to producing a better governor than the old centrifugal ball governor introduced by James Watt. Into the wide question of the best means of getting a regular number of turns out of an engine, it would not suit our present purpose to enter; but mechanics need scarcely be reminded that Watt's ball governor is defective in several respects. Many experiments have been made at the Bolton Soho Works with a view to introducing a better instrument, and the greater number of the mechanical schemes brought forward at different times have been successively tried. Some nine years ago, we remember that Siemens' isochronous governor was tried here, but apparently without lasting success. We examined a new form of engine governor now being made by Mr. Hick, and one of which is very successfully regulating the large engine which drives the tool and turning shops. It has been patented by Mr. Standfield, and though its general principle is scarcely novel, it doubtless embodies patentable practical details. The inventor also proposes to employ it for a marine engine governor, great numbers of which are now in demand, as the necessity for and advantages of attaching a governor to a marine engine are now generally understood by shipowners. Its general principle—which, as we have said, it has been more than once previously attempted to practically apply—consists in employing the resistance afforded to the motion of a fan or disc in a liquid, or even fluid, enclosed in a case. The liquid may evidently be also revolved in the case against the blades. At a certain determinate speed this resistance is, of course, constant, and a variation may, by easy means, be at once brought to act on the throttle valve. An advantage is doubtless the easy means of setting the instrument by moving the weight up a graduated lever.

ON A MEANS OF INCREASING THE RESISTANCE TO RUPTURE OF HYDROSTATIC CYLINDERS.*

By ST. JOHN V. DAY, C.E.

Hitherto it has been generally assumed that the immediate cause of rupture in hydrostatic cylinders is the pressure of the fluid against their internal walls. Primarily, this is the fact, but by careful observations upon the structure of cast-iron, of which material these cylinders are usually, if not always, made it has been asserted, that although the cause of rupture has its origin with the concentration of external force within the cylinder walls, yet there is reason, as will hereafter be seen, to believe that, carried to the extent it is usual to employ in practice, this of itself is not sufficient to produce complete disruption of the mass.

It has long been known that cast-iron, when cooled in large masses (such as hydrostatic cylinders, guns, &c.), has always its portions towards the centre of a density much inferior to that at and approaching to its outward surface; and although this inferiority may be much reduced by running the metal into the mould, and allowing it to cool under the pressure of a static head of fluid metal, as proposed and experimented upon by Mr. Mallet, in 1840,† still it must ever remain an impossibility to bring up the tenacity of the interior portions of a heavy cylinder equivalent to those further from its centre. The laws of cooling themselves, at least render it impossible, however much the ingenuity of mechanics may, by the introduction of abnormal circumstances, modify them so that the permanent irregularities of stress may be diminished.

This acknowledged deterioration of the tensile value of cast-iron under the conditions above mentioned, has led to a large amount of investigation, both theoretically and experimentally, on the part of the ablest mathematicians and mechanicians, amongst whom, under the first head, may be mentioned Barlow, Lamé, Rankine, and Hart; under the second, Mallet, Longridge, and others. By the first named of the class a formula has been proposed, and which has been modified by the others, tending towards an accurate expression for the tenacity of any given cylinder of cast-iron; in all probability, that of Professor Rankine approximates most closely to the truth.‡ Various values for the

reduction of strength in large castings have been given by those whom we have mentioned under the second head, viz., Mr. Longridge stated, "he felt confident that in a mass of metal, such as that required for a 68-pounder gun, the loss of strength would be at least fifty per cent."§ The same author further on remarks:—"When that was combined with the loss of strength due to a homogeneous cylinder, it easily explained the bursting of hydraulic presses."¶

This initial drawback to the employment of iron in thick castings, has induced engineers at different periods to suggest, and in many instances adopt, means for artificially strengthening them, which, in the case of hydrostatic cylinders and ordnance, has been effected in some instances by shrinking on their exterior tubes or hoops of malleable iron, or in others by enveloping them in a series of coils of wire. But, whatever the objections may be to manufacturing cylinders in this manner, one thing is certain, that for hydrostatic presses it has but in a few instances been resorted to.

Referring again to Mr. Longridge's paper, we find it there stated, in reference to a hydrostatic press cylinder of ten inches diameter, that using the "formule of Lamé, afterwards deduced by Dr. Hart, in his calculations for Mr. Mallet, and by Mr. C. H. Brooks for the author, also arrived at by Professor Rankine by another method, the bursting strength would be 3½ tons per square inch."||

It will not be denied that up to the present time it has been impossible to obtain ordinary cast-iron cylinders of large size to resist a pressure of three or four tons per square inch—the aggregate of cylinders annually ruptured at a lower pressure fully bear out this conclusion.

The author's attention has recently been drawn to the consideration of certain observations which have been carried on for some time by Messrs. Weems, engineers, of Johnstone, near Glasgow, relative to the rupturing action of water as it obtains ingress to the intermolecular spaces of hydrostatic cylinders. It is held by these gentlemen, that the entrance of the water into the substance of the cylinder is in effect equivalent to slicing off a ring of the metal either inside or outside, thereby proportionately reducing its resistance to internal fluid pressure. The action of the water may be referred to an annular series of wedges inserted in every possible crevice in the cylinder's walls, and driven in to rend the cylinder, so that, as each wedge penetrates the substance, the tenacity of the substance is proportionately reduced; similarly, the greater the pressure, the consequently greater distance will the water obtain vent into the cylinder's substance, when rupture is very easily brought about, the extent of entrance of the liquid also depending, under any given pressure, upon some function of the density of the iron as the exterior surface is reached.

Putting x to represent the distance that the water would enter the cylinder's substance under any given pressure, d the density of the material, and ϕ the function of increased density as the cylinder's exterior limit is reached, then—

$$x \propto \phi(d).$$

It is a fact, that under moderate pressures water always does find its way completely through so porous a substance as cast-iron, and distributes itself over the surface, at first in the form of very fine particles, which by-and-by aggregate, and may be seen to run like rain-drops, in lines extending downwards. Taking it then for granted (as the firm before referred to have done) that this interstitial entrance of the fluid diminishes the tenacity of the material, it was next sought to obstruct the passage of water, and from the results that have been and are being obtained, a doubt cannot remain that this difficulty has been speedily and successfully overcome, and that ordinary hydrostatic cylinders may thereby be rendered considerably stronger within their usual working limits. The remedy for this evil consists in placing a very thin lining of a material having great density, and consequent high impermeability, between the liquid and the cylinder—that is, a thin cylinder fitting closely to the bored interior of the ordinary cylinder. The material used for this purpose so far has been copper.

We now have to show whether any truth existed in the previous considerations relative to the supposed injurious influence of the intermolecular entrance of liquid. If the tested cylinders had burst at the same pressure that unlined cylinders had previously done, it is clear that the expense and trouble

‡ Applied Mechanics, Art. 273.

of lining would have been worse than useless; but this is not the case. Hitherto an ordinary hydrostatic cylinder, unless strengthened externally, having a ram of 24 inches diameter, could not be relied upon at a pressure much above two tons per square inch—certainly not above 2.5 tons. A cylinder of this diameter, bored out and lined as we have previously explained, has been for a long time, and now is, working at a constant stress of 3.5 tons, for the manufacture of metallic pipes; and Messrs. Weems believe this press to be perfectly safe at this strain for any reasonable length of time. Until the introduction of the copper lining they found it impossible to obtain cylinders sufficiently strong to resist the pressure necessary for the manufacture of metallic pipes. The same firm have a 33-inch cylinder, also used in the manufacture of metallic pipes, and constructed in the same manner—but we do not know what they consider to be the safe working limit in this instance. That the theory here broached is no myth, is evident from the number of presses that are being constructed on the system in and around Glasgow.

The view set forth is one that for a time may meet with opposition, and it may yet receive another explanation, having reference to a chemical rather than a mechanical cause, probably the exact truth lies in a combination of both. It is generally known amongst engineers, that if the natural surface is removed from a piece of cast-iron, and that in this state it is exposed to atmospheric influences, or is placed so that steam or mist becomes condensed on the exposed surface, in a short time oxidation will have taken place to some distance below the surface, and the tenacity of the iron becomes diminished in a ratio depending upon the difference of strength of corresponding sections of unoxidized and oxidized portions; in a given specimen the tenacity will vary as a function of the depth to which the oxygen has reached. It is almost certain that after a withdrawal of interior fluid pressure, the elasticity of the cylinder acting on the intermolecularly held particles of water causes them, or a greater portion of them, to be extruded, and thus a large portion of the space they occupied is left partly empty, at that time, in all probability, the oxygen attacks the tiny pillars by which each interstice may easily be conceived to be surrounded. As this action goes on, so the tenacity of the cylinder is rapidly reduced, and, as hitherto, breakdown after breakdown has been a continual annoyance and endless expense.

ON BEARINGS.*

Of all the materials now employed in bearings, none have given such remarkable results as hard wood. It would seem, indeed, as though there were peculiarities about its texture which render it next to impossible for iron—or metal of any kind, indeed—to abrade it, no matter how excessive the pressure, so long as it is kept cool. Brass will cut although a stream of water flows over it, and in the early days of screw propulsion the end of a shaft has before now been literally welded to the iron plate provided to take the end thrust, under a sheet of water intended to keep it cool. John Penn, we believe, first proposed the use of lignum vitæ strips as a lining for the bushes of screw shafts in the dead wood. Before fitting them on board ship he tried many experiments with very singular results. Under pressures as low as 200 lb. per inch iron cuts into bearings; with pressures of 6 cwt. iron cuts into iron, no matter what the lubricant; and with pressures of about 10 tons, surfaces of the hardest steel which can be produced rapidly abrade each other; but bearings made of strips of lignum vitæ, inserted in dovetail grooves cut in an ordinary brass have borne 8,000 lb. per square inch without showing the slightest symptom of wear. With pressures of nearly 2 tons to the inch slight scratches originally existing in the wood were not cut out after the shaft had run for hours. But one condition is necessary to the complete success of hard wood bearings, and that is simply that they should be kept cool. Neither oil nor grease seem to suit them, but under water they will wear almost for ever. Thus a stern bush lined with lignum vitæ strips, fitted on board the Himalaya, after the ship had steamed 20,000 miles, remained as perfect as the day it was put in, not the slightest trace of wear being perceptible. Part of the stern bush of the unfortunate Royal Charter, wrecked on the Welsh coast, is preserved in the Patent Museum, South Kensington. It was fitted up with lignum vitæ strips, which are as good as the day they were fitted. In practice it appears that the iron and wood are in direct contact, the water merely acts as a conductor to convey away the

heat generated, particularly under heavy pressures, the difference between the character of surface of the two materials apparently precluding all interlocking of particles. Water is not a good lubricant, squeezing out under very moderate pressures; but it acts very much more efficiently in conveying away heat than either oil or grease. No lubricant can discharge its office properly unless it possess such a capacity for caloric that it can absorb and remove, either by its evaporation or otherwise, the heat which is invariably generated in greater or less degree by every form of friction. Grease acts almost altogether by reducing friction. Oil, both by reducing friction and carrying away heat, and water almost altogether by preventing any considerable rise of temperature; and, therefore, as a general rule, oil is the best lubricant. In the case of wood bearings, however, it is neither necessary nor advisable to keep the surfaces out of absolute contact. The wood, so to speak, acting itself the part usually taken by grease or oil, it only remains that the heat generated should be carried away, and this the water flowing along the shaft between the strips and leaking into the screw alley, does effectually.

We have said that under loads of 10 tons per inch the hardest steel cuts into each other, but under moderate pressures their wear is infinitesimal, and the frictional resistance very moderate in amount. Yet in practice large steel journals working in steel bushes have given very indifferent results. They have been tried in the case of the crank pins and coupling rod ends of locomotives more than once, but at present their use is almost, if not altogether, confined to such mechanism as the link motion of locomotive and stationary engines. The great obstacle lies in the difficulty of rendering a large steel surface equally hard all over, and of preventing distortion in the bush during the process of tempering. If a hard spot exists in the journal it is certain to cut into the bearing, and *vice versa*. It is to be remembered, however, that but for steel wearing surfaces, locomotive valve gear would certainly never have possessed the finish or worked with the efficiency and durability it actually manifests, and manufacturers of the smaller classes of steam machinery might probably find it worth their while to extend the application of steel bushes even to connecting-rod ends and crank shaft bearings.

GENERAL NOTES.

SELF-ACTING BRAKE.—Reference was made a few weeks since in the letter of one of our local correspondents to an improved self-acting brake intended for use on common roads, invented by Mr. R. B. Mitchell, of Sheffield. It appears that in ordinary practical use the brake proves quite as efficient and valuable as was anticipated from the experimental trials. By a simple and ingenious connection with the shafts of the vehicle to which it is applied, the brake is lifted from the wheels in ascending a hill, and in the ordinary forward motion of the carriage, but upon a down-hill movement being commenced the brake is instantaneously applied, and increases in power as the steepness of the descent increases.

USE OF GLYCERINE FOR MOISTENING MODELLING CLAY.—The last number of "Cosmos" records some experiments on the use of glycerine instead of water for moistening modelling clay. Clay first well dried and then rendered plastic by admixture with glycerine was kept in a hot room for two months, at the end of which time its plasticity had not in the least diminished. Clay rendered plastic by glycerine would seem to be capable of being used over and over again indefinitely, just like wax, with the advantage over wax of always retaining the same consistency and degree of plasticity, neither being hardened by cold nor softened by heat.

PATENT LIST.

(From the Commissioners of Patents' Journal.)

LIST OF SPECIFICATIONS, &c. PUBLISHED DURING THE WEEK ENDING 18TH NOVEMBER, 1865.

77. Compressed bricks, H. Chamberlain—104.
78. Breach-loading fire-arms, A. Meyer and M. Meyer—84.
79. Preserving meat, T. B. Belgrave—44.
80. Treeding wood for the manufacture of pulp, W. Clark—44.
81. Artificial fuel, D. Gallafent and F. Pontifex—44.
82. Working the valves of steam engines, J. F. Spencer—84.
83. Reefing and furling sails, H. Coutanche—101.
84. Topograph, A. F. Lendy—84.
85. Cutting iron pipes, W. E. Gedgo—104.
86. Gas tongs, W. E. Gedgo—104.
87. Spring mattresses, W. E. Gedgo—84.
88. Engraving upon glass, R. A. Brown—44.
89. Steam hammers, J. Ramsbottom—104.
90. Opening and carding cotton, &c., R. Tempest—18, 44.
91. Registering distances and speed, C. M. Bathiat—64.
92. Locks and keys, J. F. Heath—31.
93. Extracting latex from banyan, &c., A. G. Lock—64.

94. Furnace flues, A. Cooper—44.
95. Railway carriages, R. Chidley—18, 44.
96. Coal-gifting machinery worked by compressed air, J. G. Jones—18, 44.
97. Signalling on railway trains, I. Goodlad—44.
98. Covering for telegraphic cables, J. Fuller—44.
99. Spring mattresses, E. T. Hughes—84.
100. Distributing liquid manure, W. Russ—104.
101. Electro-magnetic brakes, F. Barnes D. Hancock and E. Cowpe—84.

* Specifications will be forwarded from the Commissioners of Patents' Office, Southampton-buildings, Chancery-lane, by post on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post-office Order, made payable at the Post-office, 5, High Holborn, or Mr. Bennet Woodcroft, her Majesty's Patent Office. We cannot undertake to forward Specifications, or Books advertised from the office of THE ENGLISH MECHANIC.

A REALLY GOOD CIGAR.—It is said with truth that there are few things money will not procure in this great metropolis; but the lover of a good cigar has some reasons to doubt the applicability of the assertion. Pay what you will, and, in nine cases out of ten, you will procure a nasty ill-favored "weed," provocative of nausea and disgust, but it is not because the genuine article is so scarce as to make it an unobtainable luxury. If we require evidence of this fact, we have only to patronize the Imperial Tobacco Manufacturers, of France, at 109, Strand, W.C., for here, we are happy to say, we can always get a very excellent cigar at a very moderate price. The articles vendible at this superb establishment are made up in bundles of six, and are sold at prices ranging from sixpence to three shillings. The 6d. bundle are a marvel of cheapness, and it is difficult for an old smoker to realize the fact of six really good cigars being procurable at so ridiculously low a price; nevertheless the fact is indisputable, and the alone should ensure the Imperial Tobacco Manufacturers an extensive patronage.

HOLLOWAY'S PILLS.—Enjoyment of Life.—When the blood is pure, its circulation perfect, and the nerves in good order we are well. These Pills possess a marvellous power in securing these great secrets of health, by purifying and strengthening fluids, and solids. Holloway's Pills can be confidently recommended to all persons suffering from disordered digestion, or worried by nervous fancies or neuralgic pains. They correct acidity and heartburn, dispel sick headache, quicken the action of the liver, and act as alteratives and general purgatives. The delicate and delicate may take them without fear. Holloway's Pills are eminently accessible to invalids of irritable constitution, as they raise the action of every organ to its natural standard, and universally exercise a calming and a restorative influence.

VOL. II.—No. 37.]

FRIDAY, DECEMBER 8, 1865.

[PRICE ONE PENNY.]

CROSSLAND'S IMPROVEMENTS IN STEAM ENGINES FOR BLOWING, PUMPING, &c.

Letters patent have been granted to Mr. James Crossland, of Ashton-under-Lyne, for improvements in steam engines for blowing, pumping, or forcing air, pumping water, driving machinery, &c., and in the construction of the houses or beds of steam engines. One part of these improvements we this week illustrate. The first part of the invention relates to blast engines for pumping or forcing air, and its object is to form a direct acting steam condensing blast engine, dispensing with the beam hitherto used with condensing engines, and consists in a combination and arrangement of a steam cylinder, blast cylinder, and air pump cylinder for the condenser, so that the pistons are all connected to the same piston-rod or a continuation of the piston-rod of the steam cylinder, &c. The second part of the improvement relates to direct acting condensing steam pumping engines, and consists in combinations and arrangements of such engines as are described under the first division of the specification. The third division applies more particularly where a number of independent steam engines are required, such as steam hammers, rivetting machines, blowing engines, and other ordinary otherwise high-pressure engines; and these may be situated in various places, and in different rooms; and this part of the invention consists in arranging so that each steam hammer, &c., will discharge its exhaust steam into a main pipe leading to a common or general condenser. In ap-

plying this part of the invention to steam hammers the patentee forms a vacuum with an air pump and condenser or main pipe and piping, with or without a jet of water in the said condenser, into which the steam is discharged from the hammer. The using vacuum with steam hammers is applicable to all forms, but the patentee states that his improvements give rise to new features and modes of using and applying the said vacuum so obtained by an air pump as described, and these are as follow:—Using the steam with the vacuum acting on the top and bottom side of the piston of a steam hammer, namely, as used double acting; or when the steam with vacuum is used single acting, namely, only on the bottom side of the piston of the steam hammer, as shown in Fig. 6, with or without the atmosphere acting on the upper side of the piston, with open-end cylinder, being an atmospheric steam engine; or the cylinder may have a closed tap, in this case a compression of air will take place; or the steam hammer may be made on the single acting system, with atmospheric pressure acting upon the under side of the piston, as shown in Fig. 7, having steam and vacuum applied to the upper side of the piston, which is regulated by the working slide or other valve J, and its working gear and handles J'; when not required to be at work, the vacuum communication is shut off from the steam hammer by the stop-cock or valve *w*, and in like manner the steam communication by the stop-

cock or valve *w*. Figs. 1 to 7, inclusive, represent otherwise high pressure steam engines, steam hammers, blowing engines, and rivetting machines, being or required to be situate in various places or rooms in manufactories, as shown in Fig. 1, which is a section of a manufactory with five storeys R¹, R², R³, R⁴, R⁵, having steam engines A, A, A, driving as many lines of shafting, T, T, T, as may be necessary, arranged in any convenient manner, and by means of these arrangements, as described, transverse and upright shafts, and wheels for speeding and transmitting powers are dispensed with. Each of the otherwise high pressure engines is so arranged that its exhaust steam is discharged into a main pipe *w*, leading to a common or general condenser, D¹, in connection with an air pump C¹, and which said exhaust steam would in non-condensers have been exhausted into the open air, or otherwise. A general or common vacuum is made by an air pump or condensation of steam available for land or stationary engines. If the main piping W, W, is extensive in its length and disposition it will necessarily act in a great measure as a surface condenser, and may be placed as much exposed to the action of cold air or of water as may be found convenient; by this means a very little jet of water will be required to complete the vacuum made permanent by the air pump. The air pump C¹ is worked by a special steam engine for that purpose, or an air pump and condenser already in use

for other purposes may be made use of, thus facilitating the adoption and use of the patentee's invention of changing non-condensing engines into condensing, and securing the additional power and economy. A stop-cock or stop-valve is used to close the communication between the steam engine and the air pump and condenser, and this stop-cock or valve may have two ways, which when closed to the air pump may open to the atmosphere; this stop-cock or valve will close the air pump connection, whilst that at W. closes the boiler connection for steam.

ANSWERS TO CORRESPONDENTS.

ALL letters intended for the Editor should be addressed to 75, Fleet-street.

LETTERS applying for information to be furnished by post cannot be attended to.

CORRESPONDENTS are requested to keep copies of their drawings and manuscripts, as the Editor cannot undertake to return such as may be rejected.

E. KENT.—The firms are so numerous that it will be best for you to advertise in one of the daily papers.

J. K.—Send the letter to us at 75, Fleet-street, and Mr. Taylor will receive it.

T. W. D.—Can obtain the information of any practical man. Two or three answers to Henry Williams already forwarded.

HENRY SPICER.—Search back numbers, the question has been answered. If still in doubt write again. WILLIAM WILLIAMSON.—Received.

D. V. F. C.—Mr. Menz, Revenhoe-street, Greenwich. AN AMATEUR MECHANIC.—The first would be costly to make, and require many diagrams for explanation. For the second, search back numbers.

J. LONDON.—Why not have returned the engine, if it did not suit you. Explain yourself more clearly.

H. BUDN.—See the "Boy's Play Book of Science," or you can purchase one ready made at a less cost than you can procure the chemicals.

ROBERT THOMPSON will receive an answer per post in a few days.

WILLIAM WILLIAMS will see that his letter was forestalled. TORRIELLI is recommended to write to Mr. Slugg, 214, Stretford-road, Manchester, and any information will be gladly given.

ATHELSTANE is advised to apply to Mr. Slugg, as above, or to Mr. F. J. Cox, optician, 23, Skinner-street, Snow-hill, London, who will furnish price list and directions to construct a cheap telescope for 3 stamps. Magnifier is referred to the above.

W. B.—The letter has been answered too often; search back numbers. If thinking of going into the business, it will be safest for you to pay some practical man for a few lessons.

R. GUINELL.—Any artists' colourman will explain the matter to you; we cannot spare space.

BREAN DOWN.—Good.

KEENE BROS.—Virtue, Publisher, Amen Corner, Paternoster-row, London, will supply you with the whole series. T. Jackson will most likely do so.

NUKKE.—Received after other communications.

YOUNG PLUMBER.—We cannot undertake to guide you; our space is valuable, and the necessary engravings would be costly. Try Spence, publisher, Bucklersbury; or Virtue, Amen Corner, and procure the necessary works.

T. J.—Steam pressure. No inclosure.

WASHER.—Send to T. Dunbar, 4, Lewes-road, Brighton.

T. DUNBAR.—Forward the drawing to us. The plates can be obtained of any small type founder. The ink purchased of any chemist; it is useless to make it in small quantities.

SILK.—Of most mathematical instrument makers, price from 4s. upwards.

A. O. Y.—See lists in Post-office London Directory.

AN OLD CLERK.—Next week.

G. H. DUNMAN.—Thanks for your courtesy; we may perhaps treat on the subject again.

CENA.—Will see that the subject has already been treated upon. Try the treatise of W. Binns, published by Spence, Bucklersbury.

W. AUSTIN, C.E.—Thanks for communication, but cannot spare space.

J. H. M.—The idea is good; write and explain your views more fully.

N. J. W.—Next week.

LEDINGHAM.—Cannot spare space at present.

JOHN YEADON, in answer to J. Y. D.—No sketch enclosed.

S. WATSON.—Why not ask one of the experienced draughtsmen in your office?

DUNLIE.—See list in Post-office London Directory.

H. Q. P. Z.—Only by hunting about wharfs and timber yards. The price according to the article. Why not advertise?

BLAIR, Manchester.—We do not know of one at present, but an advertisement in a daily paper would bring in any answers.

B. J. ATCHLEY.—If of simple make, the instrument would be very useful. If you cannot afford a patent, you may get some manufacturer to take it up. If you send the drawing and letter-press to us we may perhaps illustrate it.

J. L. G.—App'y to Mr. Spence, Quality-court, Fleet-street.

JAMES LITTLE.—The drawings, you perceive, have not been lost sight of.

JOHN B. WILLIAMS.—The particulars have already been entered into as closely as we can spare space for.

JIM.—Whether a make would suit you.

MAGNETISM.—Next week.

W. H. C.—Of any manufacturing chemist. Your second communication appears in another column.

J. J. Junior.—Received, but forestalled by another contribution.

A. NOVICE.—Of any respectable stationer. GLOUCESTER ENGINE DRIVER.—Mr. N. P. Burgh's work is sound and practical, and will be of great use to you. It is published by Spence, of Bucklersbury.

R. F. W.—WATERPROOFING.—In a previous number we informed you that articles had already appeared on the subject. Thanks for the trouble you have taken.

JOHN HARTMAN.—The matter is so very simple that you had better ask the advice of some experienced journeyman.

J. O. S.—MARKET PRICES.—In making fresh arrangements for the new year, we will bear your suggestion in mind. We are glad that the article was of use to you.

AN ASPIRANT.—A sound education followed by close study of all appertaining to naval matters. Above all a real love of the profession.

H. J. LILFEE.—Try again.

B. FARNWORTH.—Received, but previously answered by another.

T. K.—Some instructions have been published in our first volume. The stains and directions are sold by most respectable oil and colour dealers. See Post-office London Directory.

T. VALENTINE.—Received.

A. FLEMING.—Will endeavour to forward.

HENRY NORTON.—You can purchase one complete for half the price the wheels will cost you. Try the *Horological Journal*, 61, St. John's-square. We really cannot spare the space.

T. A. W. G.—Search back numbers.

INQUIRING GEORGE.—If your lamp is properly fixed, you can use nothing better.

HORACE.—A liberal education, knowledge of mathematics, skill as a draughtsman, and study and practice while young, in an office where plenty of business is transacted.

Several letters remain over till next week for answer.

. We have to ask our correspondents to sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them by the thousand; the same with "Well-Wisher," &c.

RECENT AMERICAN PATENTS.

ORE CRUSHERS.—A. W. Hall, of New York, claims a stamping-mill having an air-tight battery, into which air is forced or drawn through one or more inlets, and from which the pulverised material is carried with the escaping air to a suitable receiver.

PUDDLING FURNACE.—Hugh M'Donald, of Pittsburgh, Pa., claims the use of iron ore in its raw or unmetallized state, previously ground fine, and mixed into thick paste or dough with water, as a lining for puddling or boiling furnaces.

IRON AND STEEL.—James Henderson, of Brooklyn, N.Y., claims mixing manganese, or the equivalent thereof, with the ore or ores charged in the blast-furnace for smelting, in combination with and to produce crude molten iron, to be directly converted by the pneumatic process.

CARBURETTING AIR.—Erasmus Allington Pond, of Rutland, Vt., claims the method of charging atmospheric air with the vapour of hydro-carbon fluids, by the discharging the air through contracted openings into the mass of fluids; also, of charging atmospheric air with the vapour of hydro-carbon fluids, by dividing the column of air, and discharging the same into the liquid in small streams.

INCORPORATION OF STEAM-BOILERS.—A. F. Porter, Philadelphia, claims the apparatus consisting of a conductor armed at one end with a series of points, or their equivalents, and connected at the other extremity with the shell of the boiler, the whole being constructed within it at some intermediate point by an insulated set of cement.

CUPOLA FURNACES.—Annes A. Lincoln, of Norton, Mass., claims the arrangement of the steam-jet and air or blast apparatus, so as to cause the commingled currents of vapour and air to enter the furnace at a point above the grate or fuel base without first going through it, meaning specially to claim a cupola furnace as made with tuyeres and steam-jets combined together and arranged with respect to its hearth.

ROLLING IRON AND STEEL.—D. Hall, Pittsburgh, claims the use in one set of housing of two pairs of rolls arranged with their axes all in the same vertical plane, the upper pair being geared together so as to pass the iron or steel through between them in one direction, and the lower pair being geared together, so as to pass the iron or steel through between them in the opposite direction, for the purpose of enabling a continuous strip or band of metal to be passed backwards and forwards between the rolls, and thus operated upon at several points at the same time, and for other purposes; also the combination of the guide roller, and adjustable guide, and curved guide box, with one or more pairs of rolls.

THE ENGLISH MECHANIC.

Every Tuesday, One Penny. Monthly Parts, 5d. Now Publishing, complete, the First Volume. Title Page and Index, One Penny. Cases for binding, One Shilling and Sixpence. It is solicited that all back Numbers be ordered at once.

All the early Numbers have been reprinted. It is therefore necessary that sets be made up at once, as there will be no further reprints owing to the great expense they entail.

147, FLEET-STREET, LONDON, and all Booksellers.

OUR MONTHLY PARTS.

Part 8 of THE ENGLISH MECHANIC, in coloured wrapper, is now ready.

Price 6d. only! Post free, 7d.

All back Nos. have been reprinted, and can be had direct from our Office, or through any bookseller.

A Christmas Present or New Year's Gift for the Apprentice or Improver!

Now Publishing THE FIRST VOLUME

of

THE ENGLISH MECHANIC,

A Record of Mechanical Invention, Scientific, and Industrial Progress.

UPWARDS OF ONE HUNDRED ILLUSTRATIONS.

Hundreds of Useful Recipes, and Thousands of Hints useful to Old and Young in all Trades and Professions.

Handsomely bound, only 4s. 6d.; post free, 5s.

OFFICE, 147, FLEET-STREET, LONDON, and all Booksellers.

TO ADVERTISERS.

As the ENGLISH MECHANIC addresses itself to the largest and most intelligent portion of the community, and is the only Paper of the kind established, it offers unusual advantages as an advertising medium.

SCALE FOR ADVERTISEMENTS:

Half Page	1	0
One column	3	0

Post-Office Orders to be made payable to GEORGE MADDICK, Fleet Street Branch.

Advertisements to be sent not later than Friday. Letters to the Editor to be forwarded to 75 Fleet-Street.

OUR CHRISTMAS NUMBER.

In announcing his intention to publish an enlarged Edition of THE ENGLISH MECHANIC as a Christmas Number, without any increase in price, the Proprietor respectfully submits that he thereby affords the many thousands of readers and numerous contributors, an opportunity of each contributing a something as a Christmas Treat for his fellows—some little "trick of trade" (in the good and true sense of the word); some improvement in tools, anything, in fact, which may be of value to brother workmen, and will assist in the promotion of feelings of kindness and good fellowship, which the season is so eminently calculated to call forth. The Editor will not fail on his part, and will be glad to find a hearty response to this challenge to do mutual good.

The English Mechanic.

FRIDAY, DECEMBER 8TH, 1865.

THE "MECHANICS' EXCHANGE."

WE do not mean a grand building in the Italian or any other style, in which journeymen, their employers, and amateurs may congregate and exchange opinions on matters, but what may in the end prove of far greater value, and which we will now proceed to explain. At times we have had requests sent to us for sketches and plans, which in the nature of things it was simply impossible for us to comply with; sketches and letters have been sent to us to be forwarded to contributors, and this we have willingly done and continue to do, knowing how beneficial such an exchange is in general, both

in rubbing down angularities in opinions and fur, bisking up those which were sinking into "remains," for want of proper expression. In no single thing has this proven of more benefit than in connection with the lathe; and this has been well evidenced to us in many a letter of thanks. That this system should be extended appears a generally felt wish on the part of our subscribers; and, therefore, we propose to open for their benefit an "Exchange." Respecting the lathe, we advise "an interchange of sketches, impressions on rice paper, or better than all, stereo-photographs of specimens in turnery. In nearly all the works on this subject, the plates are, with few exceptions, confined to plain surface ornamenting, while such subjects as, say necessities for ladies' work-tables, paper weights, ring and watch-stands, bouquet-holders, trays, cups, vases, counters, chessmen, &c., or composite works of a more elaborate nature of architectural design, capable of being finished on the lathe, with or without revolving cutters, are not at all represented." This is the opinion of many who consider themselves enthusiasts, but whom we consider simply sensible amateurs. Again, in electricity and its reduction to a workable motive power there are many ideas afloat among our readers—exchanges could be made of tracings here. In various labour-saving appliances connected with and apart from all descriptions of lathes; much could be done in casting, soldering, bronzing, tinning, pattern-cutting, templates in general, and ten thousand other things, for there are always ideas extant which reduced to tracing paper, exchanged, and recorded, will cause others to think and ponder upon, and, perhaps to mature; and thus the rough notion of an inventive mind benefits the community at large.

One advantage of our scheme is this: A person turns off one pattern at the lathe, he desires others, with rough notes of the "how" to do it; he sends us half-a-dozen, each signed with his name and address, and stamps, and says what he would like in exchange; in turn, we insert a notice to this effect:—

"**SERRIS:** Product of geometric chuck combined with rose engine. In exchange for do., oval chuck with do."

Or whatever the thing may be. The notice will produce its answers, which will be forwarded at once to their destination. And so on with everything else. And thus it will happen that, in the case of the workers at the lathe, each may in time become possessed of an excellent collection of examples and notes, making up a volume of reference, the value of which to them it will be impossible to estimate.

We are ready to take this in hand at once, and we have little fear of the result.

Furthermore, no doubt many a thing will come to hand which "exchange men" would like to see printed in *THE MECHANIC* for the use of our thousands of readers—for the success of our little venture is most marked;—publicity will be given to all such as may prove of real interest to the class for which it is designed.

Much of the matter and illustrations already volunteered by contributors has proven of great value to the readers in general; in fact, hundreds of them have informed us that one or two things, instancing them, have proved, to them, worth fifty years' subscription to the journal. We do not doubt it, or that what they in return have forwarded for publication or exchange has been found of equal value to those concerned.

We leave the "exchange" matter entirely in the hands of our readers; it is for them to determine whether it shall be carried to a successful issue or no. If they take our advice, they will immediately set to work, and, in addition, not forget, in the fast approaching festive season, to wish success to *THE ENGLISH MECHANIC'S EXCHANGE*.

CLAY BINDERS IN SOLDERING.

SIR JOHN ROBINSON says that the Asiatic goldsmiths seldom use binding wire for light work, they have always beside them a little dish of a tempered mixture of clay and sand or powdered brick, with little portions of which they form connections and supports for the pieces they mean to solder together. Thus, if two tubes have to be joined in the form of the letter T (inverted whilst being soldered), they first warm the lower piece, and then dab on a little at a time of the mortar (leaving the joint clean) until the inclined props of the clay run high enough nearly to touch the upright piece, which being warmed and set in its place, the connection is completed by a further addition of the mortar, which, when heated over charcoal, becomes quite firm, and supports the pieces whilst the solder is running, even in works of pretty considerable size.

THE ENGLISH MECHANIC.—HIS RISE AND PROGRESS.*

(Continued from page 113.)

If I rightly understand these societies, they are in the highest degree calculated to elevate and to render more efficient the class for whose benefit they came into being. Studiously marking out for avoidance the dangerous rocks and quicksands of trade politics, the framers of our rules, the honoured founders of this Association, drew up a code of laws which must, if strictly adhered to, save our barque from shipwreck; and strictly has it been hitherto, and will it be in the future adhered to, I am certain. This Association, I need scarcely tell my present hearers, does not consist of a band of scientific "Fenians," meeting in secret conclave, and meditating the ruin of their rulers—the Master Engineers of Great Britain; but rather is it a gathering of workers in the fields of wisdom endeavouring to glean facts which shall make them better men and better agents of their employers. It is astonishing to us that any members of the last-named class should have ever entertained an opposite opinion of our meetings and of our proceedings. The mistake into which they fell, nevertheless, was perhaps a natural one; it has passed away, and it is not for me now to call up its ghost. Employers have attended our gatherings, have partaken of our festivities, and have complimented us upon our growing numerical and financial strength. In this latter respect, too, they have materially assisted us. If, unhappily, differences have during the current year arisen in regard to the dispensation of a certain portion of our funds, those differences exist no longer—at least, they do not actively exist; and in a latent form, so far as we are concerned, at least, they have died out. We regret that they ever manifested themselves, and are anxious only to maintain peaceful and pleasant relations with one and all the employers of engineering labour in the United Kingdom.

It has been my warmly-cherished desire from the moment when you unanimously accorded suffrages first placed me in this chair, down to this hour, to obtain for this Society the good opinion and the co-operation of master engineers. I believed, at first, that the clouds of misconception through which the Society was seen by the employers, and which gave them a distorted notion of our doings, might be dispelled, and dispelled, I am thankful to say, they have been. This Association, of which I am proud to be a member, stands now before the general engineering community in its true light, and I believe is estimated at something like its real value. It is understood to mean a community of men of similar occupations, similar habits, and similar ideas, associated together in friendly union, for mutual improvement and material good—and that is precisely what it is.

It has been said, that the foreman engineer graduates in the workshop—our meetings enable him to continue his studies, and to keep pace with the rapid mechanical and scientific advancement of the time. True, the Association has not attained to the dignified position occupied by the Institution of Civil Engineers, or by that occupied by the Mechanical Engineers, but it is following worthily in their wake, and I for one do not despair of its rising—though perhaps not in my own day—to something like their eminence and usefulness. It has been urged, tauntingly, against the members of this institution, that they assemble in a tavern; but the fact is, that their limited funds will not as yet allow of their doing otherwise. There is no doubt that the great majority, if not all the members of the London Association of Foremen Engineers, would gladly meet in a hall, which they could call their own; but the very practical question next arises—where is the money to come from for providing it? The Association is on its legs, and it is walking, but it cannot run, it needs more steam to accomplish that performance! We are far from being without hope, that that "steam" will one day be generated, either from the action of internal fire, or the application of external fuel. Like Shakespeare's lean apothecary, we must plead in extenuation of our shortcomings, that our poverty and not our will conduces to their perpetuation.

Besides, there are illustrious precedents to which we may refer in justification of our present place of meeting. The Institution of Civil Engineers may be said to have been born in a tavern—the "Crown and Anchor," in the Strand, and at the Freemasons' Tavern it was for many years nursed and fed.

Before the year 1760, the title of Civil Engineer was almost unknown in this country. In nearly all

other nations of Europe, Civil Engineering was, at the date named, a profession encouraged or instituted by their Governments. The extension of manufacturing and mechanical industry at home about that period, and which state of things was so admirably described by Mr. Robertson last month, really called into existence the English civil engineer. It was seen that it would be better for establishments to be placed in new situations, adapted to the ready obtaining the raw materials, than to endure the delays and vexations to which they were exposed in corporate and privileged towns. This produced a new demand in the country—internal navigation and better roads. To make communications from factory to factory, and from warehouses to harbours, as well as to carry raw materials to manufactories, became absolutely necessary. Hence arose works not of pompous and useless magnificence, but of practical utility. Our seaports were previously as nature had left them, despite the construction, in some instances, of jetties and piers of defence. All these things and many more of a relative character, tended to the natural creation of the civil engineer; the mechanical engineer being his undoubted progenitor.

From the earliest notices of the new profession, it appears that its followers entertained that jealousy of each other which is even new to come amongst the cultivators of what are known as the liberal arts. They met in the avenues of the two Houses of Parliament, and in the committee-rooms, and each maintained the advantages of his own plans with pertinacity, and occasionally, it is said, with pugnacity. By this time Smeaton had appeared upon the scene, and was playing an important part in the drama of civil engineering. It was proposed to that remarkable man, whose career has been fully recorded by the indefatigable, but somewhat romantic pen of Mr. Smiles, that such a state of the profession, then crude and in its infancy, was highly improper, and that it would be well if some sort of meeting or an occasional soiree were to be held, where they might shake hands together, and become personally known to each other. Who the gentleman was that made this excellent suggestion is not known, but he was certainly the indirect originator of the Institution of Civil Engineers. Mr. Smeaton at once comprehended the propriety of such meetings, and the first one took place in 1771. During the succeeding twenty years the new Association made little progress, for at the end of that period it numbered only sixty-five members, not more than fifteen of whom were real engineers, employed in public works of any magnitude; the others were amateurs, or ingenious and inquiring workmen, and artificers. In 1792, the Society of Civil Engineers, as it was then termed, ceased to exist *pro tem.*; in fact, it was dissolved by mutual consent of the principal members. The untoward conduct of one gentleman to Mr. Smeaton was the cause of this disunion.

In April, 1793, the society was reorganised. Mr. Smeaton, who had consented to rejoin it, having, however, died in October of the year preceding, the title was retained, and henceforth the members met on every alternate Friday, at the Crown and Anchor Tavern, during the Sessions of Parliament. One of their earliest labours was the publication of the reports of Mr. Smeaton. It does not appear that the principles of the society could ensure its permanent stability, for those reports form the only record of its transactions, and it merged into a club called the "Smeatonian Society of Civil Engineers," and which, for a considerable period, held its meetings at the Freemasons' Tavern. Its rules were very exclusive, and the result was the formation, by some of the young engineers of the day, of an offshoot institution, avowedly for the purpose of mutual improvement, and this formed eventually the nucleus—the germ of the present Institution of Civil Engineers. The first six gentlemen who associated were Messrs. William Maudslay, H. K. Palmer, Joshua Field, James Jones, Charles Collinge, and William Ashwill. Their first meeting, also at a tavern, was held on the 2nd January, 1817, and the meetings were continued until the 3rd of January, 1820, when Mr. Telford, then in the height of his fame, was requested to join the society. He did so, and on the 21st of March following he was installed as President. Its subsequent removal to Great George-street, and the valuable services it has rendered and is still rendering to the country, are sufficiently well known by all, and need not, therefore, be further dwelt upon at present. It may be stated, however, that, with all its advantages, the Institution of Civil Engineers did not possess, until very recently, that necessary adjunct—a Benevolent Fund, for the relief and solace of its decayed and unfortunate members. It is not

* A paper read by Mr. Joseph Newton before the London Association of Foremen Engineers, November 4th, 1865.

long, indeed, since a gentleman connected with the institution, who had rendered much service in his day to engineering science, and who came distinctly under the category "unfortunate," applied to the members of this Association for relief—and did not apply in vain. The founders of this society had not overlooked the possibility of some of its own associates being worsted in the stern battle of life, and, so far as it was possible, they provided against such contingencies. In my own mind I feel convinced that the case to which I allude was the proximate, if not the immediate, cause of the establishment of a Benevolent Fund in connection with the Institute of Civil Engineers—a fund which, had it existed, as it should have done, from the first, would have saved many of its members from humiliation and suffering, and itself from reproach.

(To be continued.)

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents.]

SILVERING MIRRORS.

Sir,—In an article entitled *Silvering Mirrors*, which appeared in your valuable journal some weeks since, you stated that the reducing agents used by manufacturers were kept secret by them. From several scientific works I have gathered the following receipts, which will, I hope, serve to show the sort of articles employed.

Saccharic acid is added to nitrate of silver, and then ammonia to the resulting solution—a white powder falls; this is put on the glass to be silvered, and the whole is gently warmed; a smooth coating of metallic silver is thus given to the glass. Saccharic acid may be prepared on a small scale in the following manner:—One part of sugar, two of nitric acid, and ten of water are heated together. Chalk is afterwards added to neutralize, and the mixture is filtered. Sugar of lead is then added, the powder which precipitates is washed well in water, and exposed to a stream of sulphuretted hydrogen gas. Black sulphide of lead precipitates, and a solution of saccharic acid remains, this may be concentrated and added to the nitrate.

Drayton's process, as now practised successfully in Paris, is the following, viz.:—600 grains of neutral nitrate of silver are dissolved in double their weight of water. To this are added the following five solutions: No. 1, 75 grains of carbonate of ammonia, and 10 of ammonia (of Sp. Gr. 0.98). No. 2, 30 grains ammonia same strength as last. No. 3, 1,800 grains alcohol (Sp. Gr. 0.85). The mixture is then put aside to settle. The clear liquid is then poured off, and No. 4 is added; it is a mixture of equal parts of alcohol (same strength) and oil of cassia. This is added in the proportion of one part of the essence of cassia to 15 parts of the silver solution. The mixture is now agitated, and left to settle for several hours; after which, it is filtered. Just before pouring it upon the glass, to be silvered, No. 5 liquor is added; this is essence of cloves, composed of one part oil of cloves and three of alcohol, same strength as before. This liquor must be in the proportion of 1-18th of the bulk of silver solution. The glass, which has been thoroughly cleaned, is covered with the silvering solution, and warmed to about 100° Fah., and it is kept at that temperature for two or three hours; the liquid is then decanted, and may be employed for silvering other glasses. The deposit of silver on the glass is washed, dried, and varnished.

As oil of cassia and cloves are expensive, instead of them, an alcoholic solution of grape sugar may be employed, but the deposit occurs more slowly.

Petit Jean has suggested a very good method of silvering glass. He employs a solution of tartrate of silver in ammonia. By using a solution of citrate of gold in ammonia, it is easy to gild glasses, and glass may also be platinized by employing sodio tartrate of platinum.

VINCENT C. DAVIS.

SAFETY VALVE.

Sir,—In my last communication to you, under the heading "Multum in Parvo," I drew attention to the incorrectness of a solution given by G. B. to a question relative to the safety valve, and I am sorry to find that a J. S., in attempting to correct the former correspondent has fallen into the same error, and made it infinitely worse by multiplying where only additive quantities should be introduced. This latter error may be due to typographical, but the omission of considering the safety valve lever as one of the third order, and treating it accordingly, cannot be traced to the same source, and is, therefore, a bona fide error on the part of both writers.

If you will favour me by reproducing the sketch sent by J. S., he will find that his formulae should originate from $(a \times b) \times c$, and not $a \times b$, and the effect of the weight of

lever and valve are additive quantities, and not multipliers in the formulae. The weight of valve, as compared with the area under high pressure, is so small that engineers generally do not take it into consideration; but the effect of the lever is a matter of some importance, and J. S. has not shown your readers how it is to be estimated, although that is really the only difficulty connected with the safety valve lever, and hence deserves a fair consideration.

In such a lever, having first ascertained its height, it is necessary to find its centre of gravity, which can readily be done by balancing it on a chisel point fastened in a vice. The distance from the fulcrum of this centre being formed, the lever must be considered as one without weight in

itself, but having a weight equal to its own hung on at the centre of gravity, and its effect found in accordance with the rules for levers of the third order previously given, and in forming an equation, this, which is constant, must be added to the effect of the weight or tension of spring used to keep the valve down. I may add that one reason why the weight of valve is rarely, if ever, taken into consideration is this:—The form of the seating being conical, from the moment the valve is first raised, the steam is operating upon a greater surface, and, consequently, it requires less pressure to maintain the valve in its lifted position than it did to raise it, and hence the safety valve never truly indicates the exact pressure in the boiler when an engine is blowing off.

In conclusion, both G. B., and J. S., have gone aside from the original question, they set out to solve, and which, I regret to say, my leisure is too limited to deal with; but it is one worthy of a prominent position in your columns, being both interesting and useful, and I hope to see a correct solution yet from the pen of some of your talented correspondents who may have the time and ability to deal with it.

WM. TONKES.

Sir,—I don't often presume to interfere with scientific or other explanation kindly given in answer to the queries of a correspondent, but in your last number, Mr. E. Gregorio's dissertation upon the action of our chief luminary as a volunteer fire-engine is a trifle too far removed from the line of fact and truth to pass unchallenged.

Firstly, The Imperial Magazine of 39 years back is not a very reliable authority on questions of theoretical science, I beg to submit.

In the next place, atmospheric air being a simple mixture and not a compound, it can never become decomposed by passing through fire or anything else; and the rays of the sun have not any tendency to draw off oxygen from either air, or the constituents of a coal fire. Further, if a parlour fire (or any other) be long left without attendance—is not open to a strong current of air, and is not well supplied with combustibles—my personal experience is, and I think I shall here be borne out by some few thousands of your readers, that the fire inevitably goes out, whatever meteorological phenomena may be occurring at the time, for the precise reason that a man dies when starved and suffocated there being nothing to keep him alive.

Theoretically, the action of a very powerful summer sun upon a fire is to slightly diminish the draught by raising the temperature of the air-current before it reaches the fire; but practically, this action is so extremely infinitesimal as to be quite inappreciable. When a fire is exposed to strong sunshine, its apparent brilliancy is lessened considerably (just as a gas flame is often invisible in daylight), and it may appear to be almost out, although in a slightly darkened room it would seem to burn vigorously; but the sun has really no effect whatever in extinguishing a fire any more than the interposition of a poker above the grate has the faculty of drawing it up, as some would have us believe.

Mr. J. S. Thompson is not more happy in his attempt to account for a phenomenon which never occurs except as an old woman's story. White light is perfectly imponderable, and, consequently, can be neither a conductor or a non-conductor of heat, while the effect of a blanket enveloping a person whose garments are on fire is not due to its non-conducting properties (which, *caeteris paribus*, would rather assist the fire than otherwise, acting like fire-brick or boiler-plate), but simply to the fact of its cutting off the supply of air more or less perfectly.

Referring to the subject of electrical condensers (Messrs. P. Stodhard and B. Furze), alternate sheets of new tinfoil or gold leaf, and of that very thin gutta-percha known as satin or strained sheet, will be found to answer the purpose indicated.

Under the head of a Vehicle for Colour, I find a recipe given similar to that I originated and published some ten years ago in *The Builder*, with the title of "The Exorcistic Paint."

WENTWORTH E. SCOTT, F.C.S.
Analytical Laboratory, Westbourne Park, Bayswater,
London, W., Nov. 26, 1865.

MAGNESIUM.

Sir,—In your general notes you say that magnesium has little tendency to oxidize in the atmosphere. I left a small piece of the wire exposed to a very damp atmosphere for some time, and it became very much corroded. The electric conductivity of magnesium is 25, iron 20, and copper 100. Now, copper is much cheaper than magnesium ever can be. Iron, though not quite so good a conductor, is much cheaper than either. But, supposing that magnesium was used, its light-giving property is so well known, that I should not wonder if some miscreants were to apply a light purposely. Then the continuity of the line would be destroyed.

JAMES P. BLACKMORE.

Sir,—Your compositor has made me write dreadful nonsense. In the 31st and 32nd lines of my letter, in No. 36 of *THE ENGLISH MECHANIC*, I appear to recommend Magnifier to buy a reconnoiter telescope of Salmon and Co., Princess-street, Edinburgh, (10 U.S. sent free.) This should be Salom and Co., Princess-street, Edinburgh, (10 shillings and 10 pence, sent free.) I should scarcely stultify myself by recommending a ten guinea telescope to a man who wanted to obtain one for twelve and sixpence.

A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.

OUR SUBSCRIBERS' NOTES AND QUERIES.

SECOND GLUE.—Can any of your readers inform me of a cement or glue which will not be affected by water or naphtha?—WILLIAM JACKSON.

Sir.—Can any of your readers give me information respecting square thread screw cutting, more particularly as to existing patents relating to it?—LAVATOR.

Sir.—Can any of your readers tell me how to make a black for blacking cold iron, that will dry quickly; also how to make a black and green paint or varnish for metals that dries in about ten minutes?—WALTER WILSON.

THE PLANETS.—Will a Fellow of the Royal Astronomical Society inform me why the planets describe ellipses?—C. T. WHITKILL.

JAPANESE.—Will any reader tell me how to Japan tin trunks?—B. HICKMAN.

FUSING GLASS.—Can any of your readers inform me of any kind of flux for fusing glass at a low temperature, and which will afterwards bear a heat of 800° or 750° Fahr? I believe the German glass-blowers use something of the kind in soldering their chemical apparatus, &c.—M. F. G.

BAROMETER.—Can any of your readers tell me the best way to proceed in boiling the mercury in a barometer to expel air? The tube is 1-5th of an inch bore and 4 1/2 inch external diameter, and I am afraid of cracking it in the operation; also, where to obtain ivory for the scale and vernier. I want it in the rough as I can polish and divide myself!—BRACK DOWNS.

A CHEAP GAS APPARATUS.—Perhaps some of your numerous readers could inform me how to construct a cheap and simple apparatus for making oil or coal gas, such as would supply a working man's cottage of two rooms and kitchen, with certain safety from bodily injury! Any one giving full dimensions of retorts, purifier, gas-holders, and all other other additional connections in as brief a manner as possible it will be thankfully accepted.—AN ECONOMIC CITIZEN, Glasgow.

INDIA-RUBBER.—Can you or any of your readers inform me, first, of a cheap and easy method of vulcanizing small articles made of pure sheet rubber, that they may resist cold, and not be much affected by acids?

2. Is the vulcanite or dental rubber used by dentists plastic or hard, when supplied from the manufacturers?

3. If plastic, how vulcanized after moulding to prevent getting out of shape? If hard, how softened sufficiently or moulding?—GUILLEAUME.

TUNING.—Can you or any of your readers inform me how the thread is cut in end grain mahogany, such as drawer knobs, &c., and a plan of tap?—G. D. J. Y.

TIN CUTTINGS.—Can any of your numerous contributors inform me the way to extract the tin from the cuttings of sheet tin? I want to save the tin and iron as well.—W. AUSTIN.

SLIDE RULE.—Can Mr. Tonkes inform me of any rule whereby I can bring a decimal into a fraction on the slide-rule at one setting of the slide?—C. B. M. S.

ELECTRICITY.—Will Mr. Tonkes or any of your readers kindly inform me how to construct an ebonite plate for an electrical machine, or where I can purchase one, and the price of one about one foot in diameter? also, what kind of cushion for the rubber is required to excite the plate with?—TAMBO.

MAGNET.—I tender my sincere thanks to Mr. Tonkes for his promptness in replying to my queries. He would still more oblige me by telling me the number and length of wire coiled on the temporary magnet in magneto-electric machines?—J. C. WIGG.

BRONZING.—I have a bronzed coffee pot which has been cleaned with sand, and is now no better looking than one made in tin. Will any one kindly tell me how to re-bronze it, so as to get the proper warm chocolate tint?—CHANG.

TURNING AND ELECTROTYPING.—Can you or any of your correspondents inform me of any work that treats of the geometrical chuck and medallion turning? and is there any mode of electrotyping on gutta-percha? I mean a deposit of iron?—SUSANNA.

I will take the liberty of asking your correspondent, Mr. Tonkes, one question:—How can I couple four cells of Bunsen's pile for quantity? By coupling one zinc with the next carbon, I can get a current of considerable intensity, but I have hitherto failed in all my trials to couple for quantity.—VINCENT C. DAVIS.

THANKS.

Sir,—Will you kindly insert my thanks to Mr. Furze. I have obtained Mr. Culley's work through my bookseller and have found it an exceedingly good one.

E. McG.

Sir,—If Archimedes will communicate with me, I shall be happy to give information on the machine in question. 16, Market-lane, Ipswich.

GEORGE H. SMITH.

OXIDATION.

Sir,—In answer to parrow Hawk, in No. 33, I beg to inform him that one part "fat" oil varnish, five parts highly rectified spirit of turpentine, is the best thing I have ever tried for preventing oxidation on bright surfaced steel.

CINA.

CHEMISTS' FOLDING MACHINE.

Sir,—In answer to Archimedes, I beg to inform him that I do not know that the chemists' folding machine has been the subject of a patent, but think it would be to his benefit to send his address to Mr. J. Dickinson, South street, Stockton.

L. F. R.

GAS.

Sir,—Dr. McCann will best economise his gas by taking off the elbow, and putting some coarse wool in and pushing it as near the burner as he can, and just tight enough to prevent the gas from flickering when it is full on at the main; this will require adjusting once or twice perhaps.

Then turn the gas down at the main, so that there is no more supply than the actual consumption; the result will be a steady light with a great saving of gas. I have had all my burners so treated for the last 10 years.

My best thanks to Mr. Merritt, and others of your correspondents.

D. DAVIES.

Sir,—I am surprised at the letter of Mr. Jackson, wherein he states that his patent renders my invention invalid. He seems to imply that they are one and the same thing. I do not thoroughly understand the particulars of his boilers, but I think that if they were compared, they would be totally different, although they both embrace the same principle, viz.:—the generation of steam by gas heat.

A. H. SADLER.

4, Richmond-place, Richmond-road, Dalston, N. E.

MAGNET.

Sir,—In answer to your correspondent, J. C. Wigg. A permanent magnet is made of hardened steel, and made magnetic by being rubbed with a powerful magnet or a loadstone. An electro-magnet is made of soft iron, round which is a coil of insulated wire, the ends of which are connected with the two ends of a battery.

R. W. WILLIS.

DANIEL'S BATTERY.

Sir,—Alfred Crofts will find full instructions to construct a Daniel's battery in Dr. Lardner's electric telegraph, page 126. Walton and Maherty, Gower-street, London, Price 1s. 6d. I should be very happy to lend him my book, if he is within call, or send his address.

D. DAVIES.

TELESCOPE.

Sir,—I hope you will give me space to answer, as well as I am able, the query of your correspondent, Magnifier, and that he will excuse my doing so, as his question is addressed to a particular person.

An astronomical telescope requires only two lenses; an object and an eye glass; both convex, and the object looked at will be reversed, but if the eye glass be concave, it will be erect. Fix the object glass at the end of a tube, say of tin, and the image of the object at which it is pointed will be reflected within the tube at its focus. Now place the eye glass exactly at its focal distance from this image, or distant from the object glass the length of both, and the telescope is complete. Suppose the object glass to be 36in. focus, and the eye glass 1in.; they must be placed 37in. apart, and will magnify 36 times. Of course, in two tubes, the object glass in a large one, and the eye glass in a small one, to slide in and out, so as to adjust the focus to the vision of the observer.

A terrestrial telescope requires two additional glasses. To correct the inversion of the image, place the object glass at the end of a tube, as before; if 36in. focus, at 37in. distance; fix a 1in. glass at 2in. from this, another 1in. glass now at the focal distance from this, an erect image is formed, which is to be magnified by a fourth glass of 1in. at a distance of 2in. from the last. To find the focal distance of a convex lens, hold it up to the sun against any object until the sun's image is clear and distinct; the distance between the glass and the sun's image is the focus. The flatter the glass the longer the focus. Of course, the more globular the reverse. To find the magnifying power of a telescope, divide the focus of the object glass with that of the eye-glass, and the quotient is its magnifying power.

A. PEARCE.

Sir,—In reply to D. D. D., in No. 38, referring to coupling motive power:—

If he would say what pressure is got on pistons at commencement of stroke, and where cut off, with diameters of cylinders, length of stroke, number of revolutions of crank shaft per minute; also, diameters of oscillating cylinders, length of stroke, and pressure expected to work at. If these particulars are furnished, he may probably hear something more about it.

A. STOKES.

ELECTRO MAGNETISM.

Sir,—In No. 33 of THE ENGLISH MECHANIC is a letter signed J. Tawse, suggesting the practicability of propelling vessels by electro magnetism by means of sheets of metal covering the sides of the vessel acted upon by the salt water, thus converted into a battery. I do not know if Mr. Tawse is aware of his suggestions being put to practical experiment about a month ago in the harbour of Ostend, and, to a certain extent, with a very satisfactory result.

If the suggestion applies to practicability without regard to expense caused by the destruction of the metals, I think from what I saw that it is quite possible. The experiment I witnessed was tried with a small rowing boat, which was propelled by a screw at about the same rate as with an oar; and, as I thought, very cleverly and with much promise. If by increasing the number of plates we can increase the power to any extent, I think it quite practicable, and every way worthy the attention of those who have the means and disposition to follow it up to a successful result.

R. W. WILLIS.

QUADRANT.

Sir,—J. M. S. may mark slot links on paper in the following way:—

Draw an end view of the crank and eccentrics on card; upon your paper draw a centre line, supposing it to be the centre of slide spindle and crank shaft, draw another line crossing at right angles, near one end of your paper; pass a pin through the centre of the cardboard crank shaft, and fix it to the point where the two lines cross, so that you can place it in any position. The four lines will guide in placing the crank, with the distance between the centre of formation of the sheave, and the centre of the slot in the link, in a line with the rod in your compasses, the position of both ends of the link can be found in any part of the shaft's revolution, with the distance you have for a radius describe an arc from each end of the link, and then with the same radius from the point of intersection, describe the centre line of link.

A valve moves when gear is middled, because, during a rt of each stroke both rods are going the same way.

For this reason the middle of a quadrant always moves backward and forward.

Now, then, Inquiring Jamie, that the radius of a quadrant is the distance from it to the centre of formation of the sheave; or, if it be one which does not lift, but has the die lifted in it, the length of the connecting link between the die and slide spindle is the radius.

F. H. F.

THE LINK MOTION.

Sir,—In reply to J. M. S., the steam will blow off at 69 pounds pressure per square inch, and the weight must be placed 8 inches from the fulcrum to correspond to a pressure of 60 pounds per square inch.

With reference to the link motion, the travel of the valve when the link is in mid-position is due to the eccentric rods being necessarily crossed and recrossed during each revolution of the engine; what is due to this cause varies from $\frac{1}{2}$ " to $\frac{3}{4}$ ", more or less, according to the throw of the eccentrics. In that form of link motion with the rods connected in a line with the valve spindle, it does not affect the valve at all (unless the steam is being worked expansively, when, of course, the link is nearer its mid-position), because the vibration of the link destroys the effect. This motion would otherwise produce. But, in the link motion with the rods connected at the ends of the link, care must be taken in setting the valve to see that the rods are crossed on the crank when the link is connected direct to the valve spindle, and *vice versa* when connected to a gag lever. If this is not properly attended to, the valve will have lead on the one side, and lap on the other; but if the rods are crossed, as shown above, instead of the lead being destroyed (when working expansively), more lead is given the nearer the link approaches the mid position.

To see this more clearly, let us, for example, take an engine with neither lap nor lead on the valve, the link fitted direct to the valve spindle. Now place it in its mid-position, the engine on the bottom centre, and the eccentric rods open on the crank. Now, the valve having no lap, the least motion that is imparted to it either way will open the ports; then, if we turn the engine on the top centre, the eccentrics will be reversed, and the rods, consequently, will be virtually shortened, the amount due to the crossing of the rods.

I might have gone further into this interesting subject, and shown by diagrams the position of the valve at different parts of the stroke; but, if J. M. S. will construct a model of the link motion and valve, he will understand it far better than I can show him on paper.

A Common $\frac{1}{2}$ " places the eccentrics on true enough, only it is more true and scientific to draw a line parallel to the centre line at a distance equal to the lap + lead, instead of setting it off with a pair of compasses, for, by that means you get the proper angle, when, according to his method, the angle would be too acute.

M. J. WHEATLEY.

A CHEAP TELESCOPE.

Sir,—I remit you for insertion in Notes and Queries of THE ENGLISH MECHANIC, the following suggestions to Athelstane, Magnifier, and others, for the construction of a cheap telescope for observing heavenly bodies. Procure from an optician a 35 inch object glass (that is, a convex glass which produces a focus of the sun's rays at the distance of 36 inches), and a 1 inch eye glass (that is a convex glass, producing a focus at 1 inch); employ a tin plate worker to make two tin tubes, without lap joints, one 30 inches long, and about one and a quarter inch diameter inside the other, twelve inches long, and its diameter such that it will just slide comfortably inside the larger. The inside of these tubes should be first painted or otherwise lined with a dull black. At the end of the larger tube an ingenious workman will have no difficulty in securing the object glass, so that not more than an inch diameter of it shall be exposed, and at the end of the smaller tube the eye-glass must be fixed. When the open end of one tube is inserted in the open end of the other, so that the two glasses shall be about 37 inches apart a telescope will be present which will magnify the diameter of objects 36 times, or, in other words, will make heavenly objects appear 36 times nearer. With such a telescope, the satellites of Jupiter, the crescent of Venus, and the inequalities of the surface of the moon may be distinguished. Galileo's telescope, with which he made the first discoveries in the heavens, did not magnify more. I need scarcely add that with this instrument all objects will appear inverted; but, with regard to celestial objects, this is of no importance.

This telescope I describe costs about 4s.; but, for double that sum, a very much superior one may be constructed, by obtaining a larger and better object-glass of 40 to 48 inches focal distance, the cost of which is 5s. 6d., retaining the one inch eye-glass, and having the tubes made to suit the additional greater length of focus and diameter of object glass, the possession of such a telescope may add greatly to the pleasure and instruction of those who have any taste for the sublime and wonderful facts of astronomy.

AN ECONOMIC ARTIZAN, Glasgow.

PHOTOGRAPHY AND ARTISTS.—Last week at the Associated Arts Institute, Mr. O. G. Rejlander read a paper on the Uses of Photography to Artists. The paper was illustrated by a very large number of transparencies—some enlargements, others reductions—from the better known of Mr. Rejlander's productions. Besides a number of studies from the nude, he also exhibited a large chalk drawing of Mr. Brougham, the eminent actor, made from a small photograph. In the course of his paper, Mr. Rejlander called particular attention to the value to artists of an enlarging apparatus for the amplification of small sketches, and exhibited, in an arrangement of his own, some enlarged transparencies by the aid of magnesium wire.

THE ENGINEER'S SLIDE RULE.

We are compelled through press of letters and other unavoidable circumstances to defer Mr. Tonkes' third paper on the slide rule for a week. Two papers have yet to be published.

BORING, DRILLING, &c.

As it is thought a short chapter on broaches for making rafter holes would be acceptable, it is therefore given herewith, together with the necessary illustrations. The tools are much less varied than the drillers and borers for cylindrical holes. For instance, the carpenter employs only the rimer, which is a fluted tool like the generality of his bits. It is sharpened from within, as shown in Fig. 1, and thus is fitted to act like a paring tool. Such articles as the flute are first perforated with the nose bit, and then, by means of tools of this kind, broached with taper holes, the tools bring very carefully graduated as to their dimensions. Figs. 2A is that of a German rimer, and is used by wheelwrights for inlaying the boxes of axletrees. It will be observed that the loose blade is separated from the shell by the introduction of slips of leather, or wood; also, that the detached cutter fits on a pin in the front end, and is fixed against the shaft by a collar. What is known as Hilton's rimer was invented for the purposes of the wine cooper, and by it holes are made more truly circular and the shavings prevented from dropping into the cask. Fig. 2B is a section of the stock of the instrument which consisted of a hollow brass cone, down one side of which was a slit for containing a narrow blade or cutter, fixed by screws fixed diametrically. Thus the tube was turned into a conical plane; the shavings entered within the tube, and were removed by the small end of the cone, which was fitted with a cork. Broaches for metal are of various sections, and solid; thus in Fig. 3, the half round, the edges are rectangular—more commonly, the tool is polygonal, as in Fig. 4, except that they have 3, 4, 5, 6, and 8 sides, and that their edges measure respectively 60°, 90°, 108°, 120°, and 135°. The 4, 5, and 6-sided broaches are perhaps the most general. What is called the watchmaker's broach is simply a burnisher. Ordinary broaches are very acute, and Fig. 10 represents the general angle at which their sides meet—less than one or two degrees; the end is chamfered off with as many facets as there are sides. Spare broaches are sometimes, after having been filed up, twisted whilst red hot, as shown in Fig. 9, where the rectangular section is very slightly disturbed, though the faces become a trifle concave. Whatever advantage, then, is to be attributed to the screw form: as, turned in the direction of the twist, it cuts greedily, in fact, is disposed to dig over forcibly. When turned against the twist, it requires more pressure than those broaches not twisted. The evil in this broach is that if it is bent in the direction of its length in twisting or hardening, correction is inadmissible by grinding—consequently, its use is restricted, though we fancy a carefully wrought and heated tool, hardened before the tang is squared up true, would be found a rare acquisition.

Broaches are also made for perfecting cylindrical holes. Then the broaches are made almost parallel, or a trifle the highest in the middle. Figs. 6 and 7 show them filed, with two or three planes at angles of 90°. The circular being a non-cutting part acts as a more certain base than when the tool is a polygon. The stems are made so as to pass entirely through the holes, and the tool is perhaps better known as a finishing drill than a broach. The size of the parallel broach may be increased by placing a slip of leather at the convex part. Square broaches are used to broach gun barrels, and the cutting parts of these are about 8 or 10 inches long. They are packed on four sides with wood spalls to complete the circle (See Fig. 8, in which the tool is shown supposed to be at work). The bit is progressively enlarged by the introduction of thin slips of paper between the wood spalls and the broach; for the paper, it will be seen, throws the one angle more towards the centre of the hole, and so gives a corresponding advance in the cutting angle. Philosophical instrument makers, in finishing air-pump barrels, use a broach which consists of a thin plate of steel inserted diametrically between two blocks of wood—thus producing a cylinder with a scraping edge in advance of the wood.

According to size, broaches are fixed in handles, like bradawls, or used in the brace, or in the tap winch; or, again, in the lathe like a drill. For large works broaching machines are used, being but little more than driving gear ending in a sort of universal

joint, to lead the power to the tool, which may be left under the guidance of its own edges, according to the common principle of the instrument.

The penetrating angles of broaches and drills are more obtuse than in tools for turning; and, on account of the extra friction excited by the nearly rectangular edges, it is usual to employ a lower velocity in boring than in turning equal diameters, so as not to soften the tool by the generation of heat; and lubrication is more necessary, in boring and drilling than in turning. Mr. Holtzapffel, in his book, further says that "drills and broaches form together a complete series. First, the cylinder bit, the pin drills, and others with blunt sides, produce cylindrical bodies by means of cutters at right angles to the axis; then the cutter becomes inclined at about 45°, as in the common piercing drill and cone countersink; the angle becomes much less in the common taper broaches, and finally disappears in the parallel broaches, by which we again produce the cylindrical hole, but with cutters parallel with the axis of the hole." Still, considering drills and broaches as one group—drills have thin edges, yet require the screw to put them to thin work; and though broaches have more obtuse edges, yet, because the pressure is at right angles to the cutting

edge, the greater force is supplied without a screw. Glancing at Fig. 10, and supposing the dotted lines to represent the extension of the sides to a point, the length, it will be seen, exceeds the diameter by many times, and, as Mr. Holtzapffel lucidly observes, by that number will the force employed to thrust forward the tool be multiplied, the same as in the wedge, and the broach being confined in a hole, cannot make its escape, but acts with great lateral pressure directed radially from each cutting edge, and the broach, under proper management, leaves the holes very smooth, and of true figure.

But we had nearly forgotten a point or two. Countersinks, minus a point, are made sometimes as solid cones, with a groove up one side for the reception of a cutter, deepest toward the cone's base (Fig. 5). The celebrated Mr. Richard Roberts' broach (Fig. 11) has four detached blades introduced, so as to more easily retain the angle of the broach, which blades are a trifle wedge-form in section and extension, to constitute the cone and cutting edges, and the grooves are also rather deeper behind. In restoring the blade edges, they are removed from the stock, and their angles tested, and to compensate for loss of thickness, they are set nearer to the point when replaced.

BARCLAY'S INJECTOR.*

This invention of Mr. Andrew Barclay, of Kilmarnock, consists chiefly in extending the annular nozzle used in instruments for injecting liquids, through which the liquid passes, to a much greater length than has hitherto been accomplished; also, in forming an annular passage beyond the first-mentioned nozzle, for the purpose of obtaining an annular sheet of steam or water after the steam has passed through this nozzle; by which arrangement a far superior force, both for raising and also for forcing fluids generally, is obtained.

Another improvement involves the forming of a tapered or conical condenser, into which steam or other condensable vapour is admitted, in such quantity as may be required for the purpose of injecting or ejecting fluids. In this arrangement the fluids, either injected or ejected, have imparted to them the momentum of the fluid, moving with the velocity of the vapour used rushing into a vacuum. In this apparatus the condensation may be effected in any of the modes generally used for condensing steam or other vapours.

The apparatus consists essentially of a hollow truncated cone, terminating in a nozzle placed inside a hollow cylindrical vessel, in which vessel the condensing fluid is admitted, so that it condenses the

this modification is extended to a considerable distance beyond the first or steam nozzle *x*, and becomes of an annular form by the introduction of the centre adjustable spindle *i*. This spindle *i*, by reason of its tapered form, when raised or lowered by turning the hand wheel *r*, increases or diminishes the annular space, to suit the pressure of steam employed, and the height from which the water or other fluid has to be raised. At a short distance from the aforesaid nozzle *x*, a receiving nozzle or throat *h*, is so placed and adjusted by means of a self-acting valve *l*, that when a greater or less quantity of fluid is discharged from the second nozzle *h*, the throat accommodates itself accordingly. The adjustable cylinder *r*, may be raised or lowered by turning the hand wheel *w*, through the introduction of a screw formed on itself, working in a nut formed in the upper part of the apparatus, as shown at *n*, or any other convenient appliance to obtain a similar effect—that is the raising and lowering of the cylinder to suit the desired quantity of fluid to be injected. A series of holes or slots is formed opposite the steam branch *a*, through which the steam passes to the interior of the cylinder *r*, as indicated by the arrow at *o*. To maintain a perfectly air-tight packing between the steam-branch *a*, and the nozzle chamber *p*, hemp or other elastic substance is forced into the space *q*, between the ad

injecting or ejecting fluid or vapour, thereby producing a partial vacuum in the conical chamber. The fluid to be injected or ejected is admitted through a suitable pipe or duct connected to and passing through the side of the outer vessel into a conical one, whence it is injected or ejected through the nozzle at its extremity, passing thence to any place where it may be required.

In Plate IX., fig. 1 is a vertical section of the improved apparatus. The steam enters by the branch pipe *a*; the water or other fluid to be raised enters by the branch pipe *b*; and the overflow is formed by the branch pipe *c*, cast on the lower part of the apparatus, as also the flange *d*, which flange forms the connection to the boiler or other receiver through which the fluid to be injected passes. The steam nozzle *x*, is screwed into one end of the adjustable cylinder *r*, and is surrounded by an envelope or casing *g*, leaving a free space between the outside of the nozzle *x*, and its casing *g*; this space may be filled with any non-conducting substance, or it may only contain the air enclosed in putting on the casing. The object of surrounding the steam nozzle with any non-conductor of heat, is to maintain a high temperature of the steam until it reaches the exit from its nozzle *x*, as priming is very injurious whilst forming the vacuum. The water or second nozzle *h*, in

justable cylinder *r*, and the body of the apparatus, by means of a gland *n*; the cylindrical part of which, within the body of the apparatus, and where it passes the steam branch *a*, has a series of holes or slots to admit of a free passage of the steam to the interior of the adjustable cylinder *r*. When water or other liquid has to be raised about 20 or 25 feet, it is very necessary that the lower packing *q*, should be perfectly air-tight, and this can be accomplished at any time by screwing up the gland *n*. To prevent any passage or leak of steam within and around the gland *n*, two small stuffing boxes with glands *s*, and *t*, at right angles to each other, are screwed up by means of bolts or studs when required. The adjustable spindle *i*, is kept steam-tight by the stuffing-box *u*.

The action of the apparatus may be described as follows:—On steam being admitted by the branch pipe *a*, it issues at the nozzle *x*, and on meeting the angle of the second nozzle *h*, it is deflected towards the centre spindle *i*, which again deflects it towards the nozzle *h*, in a zig-zag form, as indicated by the dotted lines. This zig-zag wave motion expels the air from the nozzle chamber *p*; and the steam, forming, as it were, an annular fluid piston, prevents any return through the nozzle *x*. So soon as the vacuum is sufficient to raise the water or other fluid to be injected, it rushes in through the branch pipe *b*, and is expelled by the steam through the second nozzle *h*, the water and steam together now forming the fluid

*From Newton's Journal of Art.

piston in the nozzle *x*. The water as yet may not have sufficient force to pass through the throat *x*; it therefore gets an outlet by the overflow passage *c*. On turning the hand wheels *z*, and *x*, so as to give both more water and steam, the force imparted to the water becomes sufficient to pass through the throat *x*, and enter the boiler or other receiver. In starting the apparatus, it is essential that the steam nozzle *x*, should be close to the second nozzle *h*, when the water has to be raised from a great depth, such as 25 feet, but otherwise the setting or adjusting of the apparatus is very similar to those now in use.

A modification of packing the adjustable cylinder *r*, is represented in fig. 2. In this arrangement one gland *z*, serves to screw up both the packings *q*, and *q'*, and by merely using a loose ring or cylinder between the two packings, one gland *z*, serves to maintain the adjustable cylinder *r*, perfectly steam and air-tight. Around the loose ring or cylinder *v*, and through it, are a series of holes or slots opposite the steam branch *a*, to admit of the steam passing to the interior of the adjustable cylinder; in other respects this modification is similar to that already described. Instead of admitting the steam by the branch pipe *a*, and the water by the branch pipe *b*, they may be reversed, as shown in fig. 3, where *b*, is the steam branch, and *a*, the water branch. In this modification the steam for the first impulse strikes against the centre spindle *l*, and is deflected towards the nozzle *h*, as shown by the dotted lines; otherwise the action and construction of the apparatus are similar to those just described. The water passing through the nozzle *h*, is expelled through the nozzle *h*, by the surrounding ring of steam, and gains sufficient force to pass through the throat *x*, into the receiver, where water or other fluids are required.

It will be observed, from the foregoing description, that water may be raised from a great depth and fed into a steam boiler or other receiver direct by the afore-mentioned apparatus.

At fig. 4 is shown, in vertical section, another modification of the improved apparatus for injecting or ejecting fluids, which arrangement is considered to be one of the most important features of the invention. The outer casing of the instrument has formed by it two water branches *a*, and *a'*, and one steam branch *b*. Immediately on the inside of this outer casing there is fitted the gland *c*, which presses upon the packing *d*, this pressure being continued further on to the next ring of packing *d'*, by the introduction of the slotted metallic collar *e*, the slots formed in which are for the purpose of enabling the water admitted through or at the branch *a*, to be carried in towards the central part of the instrument. Beneath the second ring of packing *d'*, there is placed another similarly formed metallic ring *e'*, with slots also formed in it, to enable the steam to be condensed into the annular steam space *f*, of the apparatus, and this in turn acts or presses upon the lowest ring of packing *d''*, the several rings of packing *d*, *d'*, and *d''*, forming a suitable bed, in which the barrel *g*, is capable of sliding, to be adjusted as may be required. The barrel *g*, it will be observed, forms the outer shell of the annular steam space. Inside the barrel *g*, is fitted the gland *h*, bearing upon the ring of packing *i*; this again bears upon the slotted metallic ring *j*, below which is situated another ring of packing *l*. These two rings of packing *i* and *l*, forms suitable beds, within which the barrel *k*, forming the inner annular water space *l*, is capable of being adjusted with respect to the barrel *g*. Inside the barrel *k*, there is situated the adjustable spindle *m*. Both the spindle *m*, and the barrel *k*, are actuated by the hand wheels *n*, and *n'*, in a similar way to that described in reference to figs. 1 and 2. On more particularly referring to fig. 4, it will be observed that both of the barrels *g*, and *k*, are mounted at their lower ends with nozzles *o*, and *o'*, within which is contained the non-conducting substance, or it may be an air-tight space, shown in black.

It has been mentioned that there are two water inlets or branches *a*, and *a'*, in this arrangement, in lieu of one; whilst there is only one inlet for steam. These two water branches *a*, and *a'*, are in direct communication with the two annular nozzles. When it is desired to feed a fluid of a somewhat elevated temperature, the warmed fluid is admitted through the branch *a*, whence it travels or passes onwards to the central water space *l*; but since the principle of the apparatus, and its effectual working, are chiefly dependent upon the formation of a vacuum produced by the condensation of steam admitted at the branch *b*, it is obvious that if the injected or ejected fluid be of a very elevated temperature, it will act detrimentally upon the working of the instrument by preventing so perfect a vacuum from being formed. To counteract the production of this effect, and to

secure the very effectual working of the instrument prior to the admission of the heated fluid, a colder fluid, or one possessed of a temperature sufficiently low to ensure the action being effective, is first admitted through the branch *a'*, and this coming in contact with the steam jet, causes the latter to be speedily condensed; when the cold water is impelled forward with a velocity corresponding to that of the pressure of steam used, rushing from an orifice into the atmosphere—the impelled water having a momentum equivalent to its own weight multiplied by the velocity of the flow of the steam or other impelling fluid. So soon as the action of the instrument is insured by the admission of the cold water and steam, then the heated liquid is admitted, and it is, as it were, pulled forward through the nozzle by the rushing action of the colder fluid.

A slight but important modification of this last-described apparatus may be effected by forming it without the water branch *a*, and substituting in lieu of it a port or duct *c*, shown in dotted lines extending upwards on the exterior portion of the instrument in direct connection with a passage or communication with the slotted rings *m*, and *j*, through which the fluid passes into the inner water space of the instrument. It must be borne in mind that when the instrument is formed in this last-mentioned manner, it is to be used for injecting or ejecting a fluid of a comparatively low temperature, in which case there will be formed at the nozzle two annular jets of the injected or ejected fluid, with an annular jet of steam situated concentrically between them, or, instead of this, two jets of steam with a jet of water intervening; and these arrangements effect a much more perfect condensation of the steam than when only a single jet of water is employed, as in the former modification, thus producing a more perfect action of the instrument. It will be observed that the central spindle is extended, so as to diminish the area of the injecting nozzle *h*. The screw *u* is for the purpose of adjusting the position of the outer barrel *k*. This screw is capable of revolving easily in the upper part of the outer casing of the instrument; the screwed portion of it fits into a corresponding hole in the bracket formed on the side of the barrel *k*, and it is actuated by means of a winch handle or screw key made to fit on its upper end.

Another form of injecting or ejecting apparatus is shown in vertical section at fig. 5, which consists simply of an outer casing *a*, into which a current of cold water or other fluid of low temperature is admitted by the branch *b*, and out of which it flows by the duct *c*. The use of these two branches *b*, and *c*, is to provide a continuous flow of cold fluid around the conical nozzle *d*, into which steam is admitted and condensed. When the condensation has taken place, a continuous rush of steam from the source of that fluid impinges upon the condensed portion, and causes it to be emitted from the nozzle with a momentum corresponding to the amount of condensed steam multiplied into the velocity with which the steam itself would rush into a vacuum.

Fig. 6 is a modification of this last-named apparatus, in which the whole or a portion of the condensing fluid is ejected, as well as the condensed fluid itself; this result being effected by making the nozzle to terminate a short distance within the vessel containing the condensing fluid.

The patentee claims, "First—the general construction and arrangement of apparatus with an extended annular nozzle or nozzles for raising and forcing fluids generally, as described. Second,—the extension of the central spindle of the instrument into the injecting nozzle, so as to form an annular space therein, as well as to enlarge or diminish the area of that space in the manner described. Third,—the use and application of an extended annular nozzle for raising and forcing water or other liquid into steam boilers direct, as described. Fourth,—The use of a fixed casing containing any non-conducting substance between the steam and water nozzles, for the purpose and in the manner described. Fifth,—the use of an adjustable air-tight packing between the steam and water inlets, as hereinbefore described. Sixth,—the general arrangement and construction of apparatus for injecting or ejecting fluids, in which two barrels are employed to form annular jets of water and steam, which may be either two jets of water with a jet of steam between them, or two jets of steam with a jet of water intervening, as described. Seventh,—the arrangement and construction of apparatus for either injecting or ejecting a fluid of elevated temperature in combination with a colder fluid, as described. Eighth,—the system or mode

of injecting or ejecting fluids of different temperatures in immediate contact with the steam nozzle, as described. Ninth,—the arrangement and construction of apparatus for injecting and ejecting the condensed fluid without its being in contact with the condensing fluid, as described."

CUTTING SCROLLS, FRETS, &c.

JAMES KENNAN, Dublin—Patent dated April 11, 1865.

This invention, recently published in the *Practical Mechanic's Journal*, relates to a peculiar combination of machinery or apparatus for cutting scrolls, frets, or flagee work in wood, metal, or other materials capable of being set out, and consists essentially in the employment for that purpose of a vibrating or oscillating frame, in which a fret saw is strained, such frame deriving its motion direct from a cam having two or more inclines or actuating surfaces on the first motion shaft, which may be worked by a foot lever or otherwise.

According to one mode of carrying out this invention in practice, a pair of standards of any convenient form support a table upon which the material to be cut is laid. Beneath this table there is a crank shaft, provided with a fly-wheel, and carrying also a cam, having two, three, or more inclines formed thereon, according to the number of vibrations required in the saw frame at each revolution of the shaft. This shaft may be driven by a foot lever or treadle, connected with the crank by an ordinary connecting rod. Above the table there is fitted a rocking shaft, working in ordinary bearings, and to brackets on the upper and under side of this shaft are fitted two arms, the one being above and the other below the table. Or these arms may both be

FIG. 2.

FIG. 3.

cast in one piece, which arrangement is preferred. Between the free ends of these arms is strained the fret saw, by means of a nut and screw, or other convenient contrivance. One of the various modes which may be adopted for straining the saw consists in passing a short steel spindle vertically through the free end of one or both of the vibrating arms, and to make one end of this spindle (which is split to receive the end of the saw blade) conical, with a

screw thread on such conical part. By screwing a nut along the conical screwed portion of the spindle, the saw blade will be tightly grasped and held within the split. The other end of the spindle is also screwed, but the screwed part has two flat faces filed thereon, to permit the screw rising through a washer or collar on the vibrating arm, and at the same time prevents it from rotating therein, the hole in the washer being of a shape to correspond to the flattened form of the screwed part of the spindle. A hand nut is screwed on to the end of the spindle, so that by tightening up this nut the saw may be strained to any desired extent. A more simple mode consists in screwing one end of the saw by a pinching screw to the end of one of the vibrating arms, whilst the other end of the saw is screwed, by a pinching screw, to a slide working in a vertical groove in the end of the other arm, such slide being acted upon by a set or adjusting screw, whereby the straining of the saw blade may be readily and simply accomplished.

Motion is imparted to the rocking shaft arm and saw by means of another arm or lever, which is secured at one end to the rocking shaft, whilst its lower end carries one or a pair of anti-friction rollers, which are actuated by the cam on the crank shaft before referred to. The rocking shaft, and the three vibrating arms in connection therewith, constitute one arrangement of vibrating or oscillating frame, receiving its motion direct from a cam; but of course these parts may be otherwise disposed without departing from the essential feature of the invention.

Fig. 1 of the engravings represents a sectional elevation of the improved fret cutting machines. The other two figures are details afterwards more particularly referred to.

A is the standard or main framing of the machine, which may be of wood or of ornamental iron work, which latter is preferred. B represents one of two bearings carried by the main standards, in which the main drawing shaft, C, of the machine revolves. This shaft is rotated by means of the foot treadle D, connecting rod, E, and crank, F, and carries the triple action cam, G, and fly-wheel, H. On the inner and outer peripheries of this cam, which may consist simply of a run projecting from and secured to the side of the arms of the fly-wheel, work two anti-friction pulleys, I, I, which may be covered with india-rubber on their circumferences to prevent shoving and noise when at work. These pulleys, I, are carried by the lower end of a lever arm, K, the upper end of which is keyed on to the rocking shaft, L, which vibrates in bearings, M, secured to the table of the machine. O, O', are two arms, which it is preferred to cast in one piece of a C form, and which are also keyed into the rocking or vibrating shaft, L. The overhanging portions of the arms, O, O', are balanced by the counterweight, P, and the saw blade, Q, is strained between the two vibrating ends of the C-shaped lever, as is clearly shown in figs. 1 and 3. Enlarged side and front elevations of the arrangement for straining the saw are represented respectively at figs. 2 and 3. The end of the saw blade having been passed down through a hole or slit, A, in the table, is nipped and held firmly between the side of the plate, R, screwed to the end of the arm, O', and the small plate or washer, S, by means of the pinching screw, T, whilst its upper end is similarly nipped between the adjustable vertical slide, U, and the plate or washer, V, by the pinching screw, W. This slide, U, is held in a slot in the side of the arm, O, by the pinching screw, X, which passes through a slot, B, in the slide. Y is the tightening or straining screw; it works through the end of the slide, U, and bears against the top of the vibrating arm, so that on turning this screw the slide will be drawn upwards, and the saw blade strained to any extent.

In order to blow away the sawdust at each upward stroke of the saw, it is proposed to employ a self-inflating india-rubber ball, Z, or other simple form of bellows, which is placed underneath the table, and above the lower arm, O', so that each time this arm rises it will compress the ball and expel the air therefrom, which air is directed by the tube, C, to the surface of the work at the point where the saw is operating, and thereby keeping the line of cut constantly clear to view. The work to be cut is laid upon the table, and guided by the hands of the operator, whilst the foot actuates the treadle, and so gives motion to the saw. By making two or more acting surfaces on the cam, G, any number of vibrations of the saw per revolution of the main shaft may be obtained.

The wire, the thirteenth of an inch in thickness, sustains 34-7lb., a lead wire but 28lb.

The first pendulum clock was made in 1641, for t. Paul's, Covent-garden.

DUMAS' LAMP FOR THE USE OF MINES.

By M. BEZGUNT.*

THE apparatus called Dumas' lamp utilises the light produced in a vacuum by the passage of currents of induction; it consists, then, in a necessary manner, of a battery, an induction apparatus, and a vacuum tube, called a Geissler tube, from the German manufacturer who made the first.

The battery furnishes a quantity current; this inducing current produces in the induction apparatus an induced current or one of tension; and, finally, this induced current, traversing the vacuum tube, produces there a light sufficient for conducting one in darkness, for reading characters traced on paper, or even divisions engraved on an instrument, finally for working in a mine.

The battery is of two liquids; in the interior of the porous cell is a piece of carbon, which forms the positive pole of the battery, and which is immersed in water, acidulated with sulphuric acid, marking 16 deg. on the hydrometer (for acids), to which is added pulverised red bichromate of potash. At the exterior of the porous cell is a cylinder of amalgamated zinc, forming the negative electrode of the battery, immersed in a solution of sulphuric acid to 6 deg. of the hydrometer. The cylinder of zinc has a diameter but little different from the porous cell, so that the distance between the electrodes should be as little as possible, and, consequently, that the resistance is as small as possible. The exterior case of the battery is a bag of india-rubber, at the bottom of which is placed a round piece of amalgamated zinc, which increases the surface of the negative electrode, and serves as well to support the india-rubber bag, as to protect the porous cell against any shock or shake.

The upper part of the battery is closed in a manner completely hermetic by a plate of hardened india-rubber, kept in its place by screws. Two small tubes of india-rubber, communicating one with the interior and the other with the exterior of the porous cell, give exit to the gases which are formed by the working of the battery.

The battery thus composed can give a constant light during twelve hours, at the least; but if it is not kept at work, it is preserved much longer, and can give light at the end of a week.

The expense of maintenance of this battery may be valued at one cent per hour of effective working, or 1d. for a day of ten hours; and this expense being the only one which the use of the Dumas' lamp requires, it is seen that this apparatus costs less than a Davy lamp.

The inductive apparatus does not differ essentially from apparatus of this sort employed in laboratories.

Around a centre, composed of iron wires well annealed, are wound two layers of a primary wire, called the "inductor," of a sufficiently large diameter, through which passes the battery current. Around this "inductor" is wound the induced wire, of which the diameter is much less, and of which the spires and the different layers are insulated one from the other with the greatest care. The induction circuit is provided with an automatic trembler, which interrupts the induction current, and re-establishes it with great rapidity.

The two extremities of the induction wire are placed in communication with the two metallic faces of a Fizeau condenser, the action of which upon the luminous effects of the induction apparatus is very important. To each of the making or breaking of the induction current corresponds an induced current of the fine wire of the coil, and sent into the luminous tube.

The luminous tube is a tube of glass in which a vacuum has been made after having filled it with azote or nitrogen, so that it still contains very rarefied azote. This tube is sealed to the lamp, so that it preserves its vacuum indefinitely. It shows a central chamber in which are placed two rather fine tubes, one of which has circumlocutions spread out in the same plane, which have the effect of multiplying the lighting surface, and of consequently augmenting the light.

These fine tubes are made of glass or uranium, whose fluorescent properties render more constant the light from the current of induction, which, in fact, is intermittent, although it is impossible for the eye to distinguish the intermittence. This vacuum tube, which already is of a sufficiently great thickness, is protected by a very thick exterior tube, the solidity of which is very great. The exterior tube can be surrounded with a special reflector, half cylindrical, which throws the light forward that would otherwise be lost.

A turning commutator placed above the battery

allows one to close or open the induction circuit, and, consequently, to make the light appear or disappear. The battery and induction apparatus are enclosed in a box of leather and in wood, furnished with a cover closed with screws with hardened india-rubber nuts. The commutator alone projects a nut or button in hardened india-rubber above the before-mentioned cover.

The box is supplied with a leather band, which enables the apparatus to be carried in a shoulder belt. The tube is attached to this box by conductors, seventy-five centimetres in length, carefully insulated with cotten, first a tube of india-rubber, then a second tube of india-rubber sufficiently thick, which gives a great resistance and a certain thickness to these cords. By aid of these conductors the tube held in the hand can be passed by the bearer all round him, while the box which furnishes the current rests immovable on his back, or on any support whatever.

For facility of transport the tube has also a place made on the side of the box, in which it is sustained by leather bands of such a sort that even in this position it can lighten the path of the person who carries the instrument, especially if he is supplied with the reflector of which we have spoken. In the box itself the wires which place in communication the battery and the induction apparatus, are insulated with the same care as the external conductors, terminating in the luminous tube; finally the induction apparatus enclosed in a small wooden box is placed in a double envelope of sufficiently thick india-rubber.

All these envelopes have the accessory advantage of decreasing the shocks the apparatus might receive; but their principal object is to prevent an electric spark from passing between the conductors, and firing the explosive mixture of gas in which the apparatus might be placed, which would produce the greatest danger. Everybody who sees the Dumas' lamp perceives at first sight that this danger is completely averted.

It is known that in mines it frequently happens that the gases which escape from the sides form, with the air, explosive mixtures. The introduction of an ordinary light in a mine where these phenomena are produced might cause the most frightful accidents, in producing the explosion of the gaseous mixtures of which we have just spoken. It is under these circumstances that the use of safety lamps becomes necessary.

Amongst the most used and most useful of the safety lamps is that of Davy, which might be taken as a type. The Davy lamp has several great defects—first, it may be opened by the workman who carries it, and who, when wishing to obtain a more brilliant light, would let it burn without the surrounding protection of metallic net; it might be extinguished if, as is often the case, water should fall upon it from the roof of the gallery; placed in an impure atmosphere it fails and sometimes suddenly goes out, leaving the workmen without light. Moreover, in cases where light is necessary in order to prevent danger, it may happen that one has men to save—urgent works to execute in an atmosphere where life is possible at least for a short time, and where the Davy lamp cannot burn. In such cases the Dumas' lamp would be of an inappreciable value, for it burns as well in a gas absolutely unfit for combustion and for respiration, under water, and in all the conditions where ordinary combustion lamps are either dangerous or unable to give light.

It will be remarked that there is no possibility of explosion of inflammatory gases from the spark of induction, for it only passes in vacuum (at least from the distance where the two platinum points are placed, which are sealed at the two ends of the vacuum tube); and if by accident the vacuum tube should be broken the air would enter the vacuum and immediately all light and all passage of electricity would cease.

It is known that electric currents have been used for a long time to explode powder and to blast mines. Such has been up to this time the only industrial application of the induction apparatus. The Dumas' lamp offers two means of arriving at this result. The first consists in employing the intermediary of the induction apparatus; one has only to suppress the communication between the induced wire and the luminous tube, and to attach it to the insulated metallic conductors which are attached to a Statham or Abel fuse, in which two metallic points, placed at a short distance from each other, and surrounded with sulphuret of copper, and of a small quantity of fulminate of mercury, then ordinary powder, letting escape the spark of induction and lighting the powder.

The second means employs directly the battery; it is sufficient to send the current of the battery in a

* Read before the Manchester Geological Society.

fuse specially composed as follows:—A very small platinum wire, attached to the ends of two wires which come from the battery; this platinum wire is surrounded with gun cotton first and ordinary gunpowder afterwards, enclosed and held in a small gutta-percha bag. When the current passes this the platinum wire reddens and ignites the gun cotton, which sets fire in the gunpowder used in the mine. This second means is, according to M. Dumas, the surest and most convenient.

REVIEW.

A Treatise on Gas Works, and the Practice of Manufacturing and Distributing Coal Gas. By SAMUEL HUGHES, C.E.; Revised by W. RICHARDS, C.E. London: Virtue, 1, Amen Corner, Paternoster Row.

Those of our acquaintance who are in possession of the first edition of this work have always expressed satisfaction therewith; to those of our readers who are not in possession of the work we can recommend this, the second edition of the work, as being all—and a great deal more—than it pretends to be. For the merely general reader there is a great deal of interesting matter—the man who desires to know the “why and the wherefore” of all connected with gas works and gas making, with its distribution to the humblest single flah-tail, will find what he requires, set forth in a most attractive form, and illustrated in every essential particular, in some instances lavishly.

Respecting the first patent in the matter of gas-lighting we have it here set forth that—

“In 1804 Mr. Winsor obtained a patent for an improved oven, stove, or apparatus, for the purpose of extracting inflammable air, oil, pitch, tar, and acids, from, and reducing into coke and charcoal, all kinds of fuel, which is also applicable to various other useful purposes.

“A metal brick, or earthen stove, oven, retort, or vessel, is so constructed to reduce by means of fire and heat all raw fuel of any kind into coke and charcoal, without any, or little, consumption of the fuel, by which operation the smoke being extracted from all raw fuel, is thus conducted through cold air or water into a condenser, where, after being sufficiently cooled and purified, it undergoes a natural chemical resolution into tar, pitch, oil acid, ammonia, and inflammable gas or air.

“The inflammable gas or air may be led in a cold state through tubes of silk, paper, earth, wood, or metal, to any distance, in houses, rooms, gardens, places, parks, and streets (and other places), to produce light and heat, or for any other purpose, such as for increasing and multiplying force and power.”

Going on to the struggles of Mr. Winsor, and the formation of the first company in London, we find the following:—

“Having this patent, Mr. Winsor describes himself as the discoverer, inventor, and patentee of gas-lighting, and agitated the necessity of forming a company for its full development, so that the streets, shops, and private dwellings should enjoy its advantages; but gas-lighting, like every other great innovation, was looked upon by the public with excessive distrust. In the event of its success, several branches of industry and commerce were doomed to suffer; many interests were, or supposed to be, at stake; some of the chemical properties of gas were unknown; great doubt existed as to its safety, and fears as to its salubrity; indeed, the danger of explosion was magnified to the extent that it was asserted, and believed, that a town could be destroyed by the explosion of the main pipes in the street; and interested parties, in order to prevent the establishment of gas-lighting, did not scruple, to appeal to the naval glory of the nation, and this shortly after Nelson had achieved his great victories. ‘If,’ said the opponents of the new light—‘if this becomes successful, then our naval supremacy is gone, for at present we obtain principally our artificial light from the whale fisheries: these are the nurseries of our best sailors: so if we destroy the one, the other must be affected; if the fisheries no longer exist, our navy must degenerate.’

“These objections and arguments were put forth frequently by the journals; and Mr. Winsor, who by this time had become intimately associated with gas-lighting, and in a manner constituted himself its champion, met them with that extraordinary courage, perseverance, and zeal which so strongly characterised him; but it is to be regretted that although a gentleman of superior intelligence—with the great qualities already awarded him—he lacked the scientific knowledge so essential for the fulfilment of his undertaking, and unfortunately he was not aware of this deficiency. He boldly combated all possible objections with unexampled ardour, but often committed

the most egregious errors, at one time asserting that our atmosphere in its pure state was too powerful a medicine, and that a mixture of coal-gas rendered it more salubrious; again, that gas would not explode when intermixed with air, and that its adoption would purify the atmosphere; whilst the prospectus issued by him contained most extraordinary, exaggerated, and fabulous accounts of the enormous profits to be derived from gas-lighting. All this combined to retard his progress, and had he been of a less sanguine nature, his task would have been comparatively easy. These errors often brought down upon him the greatest ridicule, in which some of the leading scientific journals took prominent part; but, undaunted, he still persevered.

“At length, after having struggled, during four years, single-handed, and, as it were, against the opinion of the world—having by his letters, pamphlets, lectures, &c., proved the advantages of gas—Mr. Winsor succeeded in 1807 in obtaining a capital of £20,000 by means of subscribers, preliminary to the formation of a company; which sum was intended to demonstrate the practicability of manufacturing and supplying gas on a large scale; also for the purpose of forming the company, and obtaining a Royal charter.

“Mr. Winsor then occupied extensive premises in Pall Mall, on the site of the present Carlton Club. On the basement he had gas manufacturing and other apparatus to illustrate his lectures, demonstrating the practical utility of gas for lighting, heating, and cooking, also its safety and salubrity; the public, on certain days, having free access to take cognisance of the process. From these premises a pipe was laid in Pall Mall to the corner of St. James’s Street westward, and to the Haymarket eastward, with lamp-posts at short intervals, including several in front of Carlton House, the residence of the Prince Regent; and thus Pall Mall was the first street ever lighted by gas, and continued so during the sessions of parliament of 1809 and 1810, whilst endeavouring to obtain an Act of incorporation and charter.

The intention of Mr. Winsor, and his subscribers or shareholders, in 1808, was to establish a company, and obtain a Royal charter of exclusive privilege for lighting all the British possessions by gas; and for this purpose they proposed a capital of one million sterling.* A memorial was accordingly presented to the King, setting forth the advantages which would result from gas-lighting, and the production and general employment of coke, praying for the concession; but after the question had been duly considered in Privy Council, it was decided that his Majesty could not grant the charter of incorporation until a Bill had been obtained from parliament authorising the company.

“The following year Mr. Winsor and his shareholders again applied, with more modern pretensions, to be established at the ‘National Light and Heat Company,’ but were strongly opposed by Mr. Murdock; and on this occasion many scientific witnesses were examined before a committee of the House of Commons, who proved incontestably that gentleman’s claim to priority of adopting gas for illumination. The evidence given is of the greatest interest; but the errors of a leading witness for the company, and the merits of Mr. Murdock, caused the application to be refused.

“Amongst Mr. Winsor’s subscribers were some eminent men of the day, and, like himself, of the greatest perseverance and zeal. They had already been too familiar with difficulties to be discouraged by defeat; and again, in 1810, they applied to Parliament, and succeeded in obtaining an Act of incorporation as the ‘Gas-light and Coke Company,’ with a capital of £200,000. But the enterprise was looked upon as so visionary, that it was asserted this Act was granted in order to make a great experiment of a plan of such extraordinary novelty.

“The royal charter was granted to the company in 1812; but the privileges accorded by that charter were neither liberal nor encouraging; for by it the company had no exclusive right, so as to prevent any other persons or company from entering into competition with them. The power and authority granted were very moderate; and whilst the company were under severe restrictions, they were confined to the metropolis, and were liable to have the charter annulled if they failed to fulfil their obligation.”

From thence we travel on through the various companies, the various methods of making and purifying gas, and all about the necessary buildings, “tools,” and “chemicals.” Coming to the chapter on retorts, we find a little bit which will doubtless be of interest to many of our readers. It is on the cement employed in attaching the mouth-

pieces to iron retorts, &c., but as it is obviously suitable to many other joints we extract the matter entire.

“The recipes for making iron cement vary considerably. Mr. Peckstone says 1lb. of iron borings or turnings are to be pounded in a mortar into a state of fine dust or powder; these are to be mixed with 2 oz. of sal ammoniac in powder and 1 oz. of flour of sulphur; the whole to be thoroughly incorporated by being pounded in a mortar. When required for use, take one part by measure of the above compound, and mix it with twenty parts of pounded iron borings, adding water to bring the mixture to the consistence of ordinary mortar. This cement may be applied in making all sorts of flange joints, as in securing the mouth-pieces to the retorts, the dip-pipes to the hydraulic main, &c.

“Mr. Clogg’s recipe is somewhat different: he uses
Iron borings or turnings... .. 32 oz.
Sal ammoniac... .. 1 lb.
Flour of sulphur... .. 1 lb.

To be well mixed together, and kept dry for use. When required, water to be added to bring the mixture to a proper consistency.

“The French employ the same purpose a cement called the Mastic d’Aquin, which is thus prepared:—98 parts of clean iron turnings, pounded and passed through a sieve.

1 part of flour of sulphur.
1 part of sal ammoniac, dissolved in sufficient boiling water to bring the whole mass to the consistency of ordinary mortar.

This cement is not prepared till required for use, and should be employed as soon as possible. The iron borings should be sifted, and perfectly free from grease or oil, otherwise if too granulated or greasy a good joint cannot be made.”

(To be continued.)

GENERAL NOTES.

IN Wales, at the old Clogau copper mine, the quartz yields about 1oz. of gold to the ton. At Castell Carn Coch an 5oz. 12 dwts. of gold were obtained from 90 cwt. of quartz from the lode and from alluvial matter.

SINCE the Russian Government gave up the working of the gold mines in the Ural Mountains, and arranged for them to be worked by private enterprise, the quantity of metal extracted has been increased tenfold.

Two iron plates 4ft. in diameter, and weighing 1,000 lb. revolved 80 times in a minute, send sufficient heat up a furnace to warm a large factory. They are turned by a hand and water wheel, and last for years.

PROFESSOR TYRDALL has succeeded in entirely cutting off the luminous from the calorific rays, and to produce not only combustion in an absolutely dark focus, but also the incandescence of platinum by non-luminous rays.

ACCORDING to the theory of the late Mr. Taylor, the granite coffer in the Great Pyramid was a primeval measure of capacity from whence is derived our wheat measure the “quarter,” of which coffer it is the fourth part exactly.

MANUFACTURE OF OXYGEN GAS.—Messrs. Parker and Tadner, of Birmingham, propose to manufacture oxygen gas by heating a mixture of nitrate of soda and quick lime. They obtain as by-products caustic soda, and a compost consisting of lime and nitrate of lime.

PETROLEUM GAS ON RAILWAYS.—The London and North-Western Railway have had some of their carriages experimentally lighted with gas made from petroleum. The apparatus containing the gas occupies half the space under one seat, and the compartments were quite as brilliantly lighted as they would have been by ordinary coal gas.

EXHIBITIONS.—We are glad to say that, notwithstanding the Fenians, the Dublin Exhibition is a success. During the last ten weeks the provinces have come in, and saved the projectors from trouble.—The Bristol Industrial Exhibition produced £3,253 14s. 11d. Of this sum a portion is appropriated to prizes, the remainder goes to the medical and other charities of the city.

IRON SMELTING IN COLORADO.—According to the *Denver News*, the business of iron smelting may now be said to be fairly inaugurated in Colorado. It appears that the Belmont furnace is in operation near Denver, and is turning out two tons of pig iron per day. The ores used are pronounced by competent judges to be the best in the world, and are excelled in richness only by the Pilot Knob and Lake Superior ores; but possess an advantage over these in the fact that they can be easier and more economically worked. The supply of ore is deemed inexhaustible and is easily obtained.

* French translation of Accum of Gas, by F. A. Winsor.

APPLICATION OF DIVING APPARATUS FOR MINING PURPOSES.

THE value of modern discoveries in connection with practical colliery operations has been completely proved within the past few weeks at the Grove Pit, near Tenby, where the enterprising proprietor, Mr. C. R. Vickerman, has succeeded in effecting a considerable saving of time, and a large amount of money, by availing himself of the services of divers, with Heineke's apparatus for performing work of an entirely novel description. It appears that in the Grove Pit the main rod, 16 inches square, of the 80-inch pumping engine, broke short off about 20 feet from the surface, and upon the new main rod being fixed, and the engine set to work, it was found that the valves (which were now entirely out of reach, the water standing 26 feet in the pit) would not act—the breakage of the main rod letting the spindle fall through the clack and seating to the bottom of the pump. According to the old method of putting in a new lift, many weeks would have elapsed before the pit would have been in working order, whilst the divers enabled everything to be put right again in from six to eight hours. The Grove Pit is 15 feet in diameter, and 630 feet deep, and is considered to be one of the finest in South Wales. Now that the diving apparatus has been once applied in a pit, there is little doubt that it will frequently be used in connection with mining operations, it being unquestionable that in innumerable instances its use would be both advantageous and economic.

CRUSHING ORE.—Alexander W. Hall, of New York, claims enclosing the crushing wheels of a machine for crushing and pulverising ore or other materials by an air-tight cover, so combined with the pan in which the said wheels work as to form therewith an air-tight chamber, in which the crushed or pulverised material is subjected to the action of a blast or blasts of air.

PHOTOGRAPHY IN NATURAL COLOURS.—Let us see what the existence of such a photographic process would imply. There must be a sensitive surface capable of assuming all hues. This in itself it would not be easy to find. But more than this: each coloured light must cause the surface to assume its own exact tint. Now in the case of a single colour, say green, it seems to me that this could only be a coincidence. It would be as reasonable to suppose that a green substance—a green wax candle—should burn with a green light, as to suppose that a green light should produce a green substance. Of course it might do so; but there is no reason for believing in any necessary connection. At this rate photography in natural colours would require an infinite number of coincidences. But I would go further. Granting that the process were discovered, I say it would be impossible to work it. For since the surface is by supposition sensitive to light of all colours, it must be prepared and finished in absolute darkness. Now I have no hesitation in saying that if the new process were as delicate as the present one (and it could scarcely fail to be infinitely more so), it would be impracticable to work it in darkness. The difficulty is evaded now by working in a yellow light, to which the film is not sensitive. Taking these considerations into account, I am not at all sanguine about photography in natural colours.—*Hon. J. W. Strutt.*

PATENT LIST.

(From the Commissioners of Patents' Journal.)

LIST OF SPECIFICATIONS, &c. PUBLISHED DURING THE WEEK ENDING 26TH NOVEMBER, 1865.

102. Teaching and transporting music, R. A. Brooman—1s. 2d.
103. Furnaces, M. Henry—4d.
104. Money tills, G. Gaze—10d.
105. Cleaning and repairing ships' bottoms, &c., R. F. Moll—4d.
106. Breach-loading fire-arms, G. H. Daw—10d.
107. Signalling on railway trains, J. B. Hill—4d.
108. Crinolines, J. Knight—4d.
109. Lubricating bearings with mercury, F. G. Mulholland and T. Dugard—4d.
110. Furnaces, W. S. Lounridge and J. Mash—10d.
111. Steam engines, W. Brooks—4d.
112. Distributing vapours for hygienic purposes, A. J. Sax—8d.
113. Steam boilers, E. Lewis—4d.
114. Umbrellas, J. Weeks—8d.
115. Cleaning grain, W. Ager—10d.
116. Constructing and paving roads, T. G. Pagano—4d.
117. Looped fabrics, W. Wilkins—4d.
118. Hydraulic steering apparatus, A. Paul and E. Paul—4d.
119. Preventing incrustations in steam boilers, G. Davies—8d.
120. Sleeve links and other dress fastenings, W. H. Richards—4d.
121. Signalling on railway trains, E. Lee—4d.
122. Pressing and cutting tobacco, A. V. Newton—8d.
123. Breach-loading fire-arms, W. Ansell—4d.
124. Ball buoy, T. Bourne—4d.
125. Ornamental flower box, G. Colven—4d.
126. Heating gases and vapours, J. Young—8d.
127. Ship and other compasses, J. Lilly—4d.
128. Roofs, F. C. Fourness—1s.
129. Preparing, spinning, and doubling fibres, J. B. Farrar and J. Hirst—4d.

131. Bone shifting machinery, W. Edwin—8d.
132. Stopping of bottles, H. J. Rogers and J. M. Scholfield—4d.
133. Males for spinning, W. H. Jones—4d.
134. Expressing fluids, J. Marshall—8d.
135. Driving rolls for rolling metal, R. A. Brooman—4d.
136. Explosive shells, J. B. Cottle—4d.
137. Ship building, J. Betteley—8d.
138. Breach-loading fire-arms, G. F. Bousfield—1s.
139. Breach-loading fire-arms, J. B. Hill—4d.
140. Treating phosphates, R. A. Brooman—4d.
141. Pianos and other stringed instruments, F. H. Lakin—1s.
142. Charging and drawing gas retorts, J. S. Best and J. H. Holden—4d.
143. Flaming and moulding wood, J. Robinson and J. Smith—10d.
144. Sewing machines, C. T. Jenkins—10d.
145. Converting reciprocatory into rotary motion, W. J. Cunningham—4d.
146. Dressing fabrics, F. H. Chauzuc—8d.
147. Working switches and signals, W. Jeffreys—1s. 2d.
148. Reeling and furling sails, A. B. Bull—4d.
149. Camp bedsteads, E. Deane—8d.
150. Cooking apparatus, S. Ballard—4d.
151. Street and other lamps, J. W. Gregg—8d.
152. Breach-loading fire-arms, W. E. Newton—1s.
153. Weaving velvet pile and terry-faced fabrics, J. Burch—1s.
154. Facing and smoothing stone, J. Coulter and H. Harpin—2s. 2d.
155. Packing for steam engines and hydraulic presses, W. R. Forster—8d.
156. Submarine telegraphy, S. F. Van Choate—10d.

* Specifications will be forwarded from the Commissioners of Patents' Office, Southampton-buildings, Chancery-lane, by post on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post-office Order, made payable at the Post-office, 5, High Holborn, or Mr. Bennett Woodcroft, her Majesty's Patent Office. We cannot undertake to forward Specifications, or Books advertised from the office of THE ENGLISH MECHANIC.

WANTED as FOREMAN in a CHAIR MANUFACTORY, an experienced energetic man, who has served in the same capacity.—Address, A. B., Post-office, Bath.

TO CONTRACTORS, ENGINEERS, SHIP

BUILDERS, COLLIERY OWNERS, &c.—Sections and Prices forwarded on application for Boiler, Bridge, Boat, and Ship Plates, Angle Tee, Beam, Girder, and Dock, Iron and all sizes; Sheet Iron, Plate, Corrugated or Galvanised; Wire Ropes for drawing, telegraph, or fencing; Black or Galvanised. Wire Ropes; Permanent, Colliery, or Tram Ropes; Hoop Iron, Bar Iron, Nail Rods, Silt Nut Iron, Gutter, Bevelled, Taper, Convex, Half Round, Bash, Tyre, and all descriptions of Fancy Iron; Bar Iron of all sizes; Wrought Iron Forgings, Castings, and Railway Material of every description.

FIRE-PROOF SAFES, LOCKS, &c.

WITH SPECIAL MENTION OF THE

"WEDGE PROOF FASTENINGS"

OF

S. CHATWOOD.

A detailed black and white illustration of a vintage treadle sewing machine. The machine features a large, ornate cast-iron frame with a decorative, scrolled base. A large flywheel is visible on the side, connected to a treadle mechanism at the bottom. The sewing head is mounted on a horizontal table, and a large spool of thread is positioned on the left side of the table. The overall design is characteristic of late 19th-century domestic sewing machines.

IN Securing, Carrying Out, and Disposing of their Inventions.—Apply to **Messrs. B. BROWNE and CO.**, British and Foreign Patent Office, 49, King William-street, London-bridge.

A Pamphlet gratis, on Cost of Patents, may be had on application

INVENTIONS secured by Patent or Registration, on moderate terms, by application to **Mr. WILLIAM BROOKES** (of upwards of 25 years' experience in such matters). British and Foreign Patent Agency, 62, Chancery-lane, London, W.C.

TO INVENTORS.—GENERAL
PATENT OFFICES.—**L. de FONTAINEMOREAU**, 4, South-street, Finsbury, London; 10, Rue de la Fidelité, Paris; 83, Rue des Minimes, Brussels. Provisional protection, 27; to complete patent, 230; French patent, 26 10s.; Belgium, 22 10s. Circular gratis on application.

PATENTS FOR INVENTIONS.—Full instructions may be obtained by applying to **Mr. W. T. RAWLE**, Office of British and Foreign Patents, 8, Small street, Bristol.

NOTICE TO INVENTORS.—Office for Patents, 4, Trafalgar-square, Charing-cross. Printed instructions (gratis) as to the Cost of PATENTS, for Great Britain or foreign countries. Advice and assistance in disposing of or working inventions. Branch offices and agencies in every Continental State and in America. Established 30 years. Full information as to expired or existing Patents at home or abroad. Apply personally or by letter to **Messrs. PRINCE and Co.**, Patent Office, 4, TRAFALGAR-SQUARE, CHARING-CROSS, W.C.

Self-acting, Turning, and Screw-Cutting Lathes,
OF THE FOLLOWING SIZES,**For Sale, and Ready for Delivery:—**

Height of Centres.	Length of Bed.
6½ Inches.	6 Feet.
7 "	8 "
7½ "	14 "
8 "	8 "
8 "	12 "
8 "	13 "
10 "	16 "
11 "	16 "

Also a large Assortment of Single and Double Geared Drilling and Boring Machines; Planing, Shaping, Slotting, Bolt Screwing, Punching, and Shearing Machines; Hydraulic Jacks, Screw Jacks, and other Tools.

Apply to **W. BLACKETT**, Hope Iron Works, 106, Southwark Bridge Road, London.

E. BOURDON'S PATENT GAUGES.—GIFFARD'S INJECTORS.

Drawings and Prices on Application to

W. T. HENDRY, & Co., 73, QUEEN STREET, LONDON, E.C.

BRITISH AND FOREIGN PATENTS AND THE REGISTRATION OF DESIGNS.

Mr. H. H. MURDOCH having succeeded to the Business of his late Father, which has been established upwards of Thirty Years, offers his professional services to inventors. A circular, containing full information respecting the various modes of securing protection for inventions at home and abroad, may be had, Gratis, by applying (personally or by letter), at his OFFICE FOR PATENTS, 7, STAPLE INN, LONDON.

PATENTS.

MR. VAUGHAN, Member of the Society of Arts, British, Foreign, and Colonial Patent Agent, 54, Chancery-lane, W.C.
Transacts every description of business connected with Letters Patent for Inventions. Provisional protection, 6 to 8 guineas. A "Guide to Inventors" free by post.

SAMUEL BROTHERS,

Suits for all Occasions
36s. to 114s.

OVER COATS
21s., 28s., 33s., 42s., 55s., 63s.
BOYS' OVER COATS, 12s. 6d. to 35s.
Boys' Suits 16s. to 35s.
50, LUDGATE HILL.
The new Book with 42 Engravings (36 being Portraits), illustrating the most fashionable attire, will be sent post free for six stamps, which sum is deducted from a purchase.

Advertisements and Communications for the Editor are requested to be sent to 75, FLEET-STREET.

ENGLISH MECHANIC:

A Record of Mechanical Invention, Scientific and Industrial Progress,
Building, Engineering, Manufactures, Arts, &c.

VOL. II.—No. 38.]

FRIDAY, DECEMBER 15, 1865.

[PRICE ONE PENNY.]

FIG. 3.

FIG. 5.

MANUFACTURE OF BRICKS.

IT has been objected to machine-made bricks that they are often extremely faulty through distortion in firing caused by the expansion of air globules which have been formed in the mixing and treatment of the raw material in the preparatory stage; at various times efforts have been made to get rid of this admitted evil, and place machine-made bricks on a still better foundation than that they now enjoy. Among the last of the patents taken out for this, combined with other purposes, is that of Mr. H. Chamberlain, of Wakefield, who, however, simply states that his invention relates to machinery for the manufacture of compressed bricks from what is known as "granulated clay," whereby distinct and separate pressures are applied to the clay at each revolution of the main shaft. The general working of the machine is sufficiently described in detailing the various parts of the machine.

Fig. 1 is a front elevation of the machine; Fig. 2 a corresponding end elevation; Fig. 3 a plan corresponding to Fig. 1; Fig. 4 is a detail side elevation of the plungers or pistons and the cams for working the same; and Figs. 5 and 6 represent respectively a detail sectional elevation and plan of the pistons or

plungers and parts in immediate connection therewith. A is the framing bolted to the bed B, and carries the main shaft C, which shaft is provided with a driving pulley D, and friction clutch E, which engages with the spur pinion F, loose upon the shaft. The clutch E is thrown into and out of gear by means of a lever G, and rod H, the latter having a screw thread formed upon it, and being worked by an internal screw thread in the boss of the hand wheel I, carried by the double bracket K, bolted to the framing. The pinion F gears into a spur wheel L, fast on the second motion shaft M, which carries a pinion N at its opposite end in gear with the large spur wheel O, keyed on to one end of the cam shaft P. This shaft is supported in bearings Q, bolted to the top of the standard A, and carries the two cams R R, for working the upper pistons (Fig. 4), as well as the eccentric S, for working the lower piston T. U, V are spur wheels for actuating the self-acting feeder; V is a fixed table bolted to legs on the inner sides of the standards, and having moulds formed therein supplied with clay from a hopper by means of the usual feeder; W is a piston or plunger which forms the bottom of each mould, receiving a rising

and falling motion from a pair of small cams R (Fig. 4), keyed on to the overhead shaft P. These cams each revolve within a frame X, to the lower end of which is connected the rod Y, secured by a nut to each extremity of the cross head Z, keyed on to the piston rod a. The upper end of this rod carries the piston W (Fig. 5), working inside the moulding box b, and its lower end when down rests upon a packing piece d, on the bed plate or foundation B; S is an eccentric keyed on the shaft P, between the snail cams R, the rod e of which is connected by a long cross pin f, with the upper piston g, working inside the main beam h, which slides up and down in vertical guides i. The piston or plunger g serves to form the indentation of the brick when a solid brick is to be produced, or to form the perforations by being provided with suitable pins when perforated bricks are required; k is the hollow plunger connected to the main beam h, fitting accurately into the mould b, the piston g working through the centre of this hollow piston (Fig. 5). The cross pin f works in vertical slots in the main beam h, so that it can move up or down without imparting motion to the main beam h.

To further explain the *modus operandi* of brick making by this machine, we may remark that, both the upper pistons *g* and *k*, with the beam *h*, being elevated, clay is fed into the mould, the lower piston *W*, being at that time in its lowest position. The beam *h*, with its hollow piston *k*, then commences to descend, the piston *k* resting upon the clay in the mould, whilst at the same time the lower piston *W* rises, and by compressing the clay against the upper pistons expels a considerable portion of the air from the particles of clay. Whilst this operation is going on the inner or pannel piston *g* continues to descend slightly, the main beam *h* and hollow piston *k* remaining at rest. The amount of this descent of the piston *g* depends of course upon the length of the slots in which its pin *f* works, and so soon as the pin *f* arrives at the bottom of such slots, the beam *h* and hollow piston *k* will be carried down still further into the mould. In the meantime the bottom piston *W*, has dropped sufficiently to find a support on the packing underneath the lower end of its rod, and thus as the upper pistons descend they will force the partially compressed brick downwards to the bottom of the mould, and as the bottom piston has by this time obtained a solid bearing, the final pressure is given to the clay by the action of the eccentric on the upper pistons as it passes its centre. The pannel piston *g* then commences to rise, and so soon as the connecting pin *f* reaches the top of its slots *f*, it carries up with it the main beam *h*, and hollow piston *k* clear of the mould. The bottom piston in the meantime rises until its surface is flush with the table, thereby expelling the compressed brick from the mould, which is then pushed away by the advance of the self-acting feeder when bringing the next supply of clay, the piston *W* descending again to the bottom of the mould in readiness to receive the next charge, when the operations are repeated. We may remark that the "novelty" in the invention is the giving three or more distinct and separate pressures to the clay at each revolution of the main shaft.

WORKING MEN'S HOUSES IN LONDON.

A praiseworthy effort is being made to erect small blocks of urban dwellings in London, with the financial co-operation of the working men themselves. The only remedy for overcrowding is, it is felt, the erection of a sufficient number of dwellings in place of those appropriated by railway companies; and as men of capital do not seem inclined to invest their money in this direction, it has been suggested that working men should combine to supply the means. A meeting was, therefore, held on Tuesday night, at the Lambeth Baths, to take the matter into consideration, and the result was the formation of a "London House Improvement Company (limited)." As it would be impossible to commence operations on the partly paid-up shares of working men, it has been decided to include another class of shares to be taken by friends of the movement, and to be paid up by calls much more rapidly. The proposed capital is £20,000, in 1,000 shares of £10 each, payable during the first two years; and 1,000 shares of the same amount, payable by instalments of sixpence per week, a small entrance fee being charged on each share. According to a tabular statement, with which we have been favoured, the houses will probably produce 10 per cent., although 8 per cent. has been estimated. At the end of the eighth year, while 5 per cent. has been paid to the shareholders, a considerable addition to that percentage may be expected, and double the number of houses can be built. Mr. Samuel Sharp architect, has, it appears, prepared plans, which it is said will avoid many objections made against ordinary model lodging-houses. It is proposed to erect separate blocks of buildings, each containing two shops and eight dwellings, the shops having two back rooms attached. Each flat will contain two dwellings, each dwelling consisting of a living room 14ft. square, two bedrooms and scullery, &c. Washhouses, drying-room, and rooms for working men who are employed at home, will be erected in the attic. The promoter of this novel scheme also intend ultimately to erect houses in the suburbs, for the same class of occupiers, who may purchase the same "when they retire from their labours" with the accumulated dividends of years. We commend the project to the notice of artisans employed in the building trades. The investment would certainly be a safe and, we believe, a profitable one. It will, however, be necessary for the promoters to appoint sub-committees to enlist the sympathies and support of working men, and so extend the usefulness of their proposal.

THE ENGLISH MECHANIC.

Every Tuesday, One Penny. Monthly Parts, 5d. Now Publishing, complete, the First Volume. * * Title Page and Index, One Penny. Cases for binding, One Shilling and Sixpence. It is solicited that all back Numbers be ordered at once.

All the early Numbers have been reprinted. It is therefore necessary that sets be made up at once, as there will be no further reprints owing to the great expense they entail.

147, FLEET-STREET, LONDON, and all Booksellers.

OUR MONTHLY PARTS.

Part 8 of THE ENGLISH MECHANIC, in coloured wrapper, is now ready.

Price 6d. only! Post free, 7d.

All back Nos. have been reprinted, and can be had direct from our Office, or through any bookseller.

A Christmas Present or New Year's Gift for the Apprentice or Improver!

Now Publishing THE FIRST VOLUME

of

THE ENGLISH MECHANIC.

A Record of Mechanical Invention, Scientific, and Industrial Progress.

UPWARDS OF ONE HUNDRED ILLUSTRATIONS.

Hundreds of Useful Recipes, and Thousands of Hints useful to Old and Young in all Trades and Professions.

Handsomely bound, only 4s. 6d.; post free, 5s. OFFICE, 147, FLEET-STREET, LONDON, and all Booksellers.

TO ADVERTISERS.

As the ENGLISH MECHANIC addresses itself to the largest and most intelligent portion of the community, and is the only Paper of the kind established, it offers unusual advantages as an advertising medium.

SCALE FOR ADVERTISEMENTS:

Post-Office Orders to be made payable to GEORGE MADDICK, Fleet Street Branch.		
Advertisements to be sent not later than Friday.		
Letters to the Editor to be forwarded to 75 Fleet-Street.		

OUR CHRISTMAS NUMBER.

In announcing his intention to publish an enlarged Edition of THE ENGLISH MECHANIC as a Christmas Number, without any increase in price, the Proprietor respectfully submits that he thereby affords the many thousands of readers and numerous contributors an opportunity of each contributing a something as a Christmas Treat for his fellows—some little "trick of trade" (in the good and true sense of the word); some improvement in tools, anything, in fact, which may be of value to brother workmen, and will assist in the promotion of feelings of kindness and good fellowship, which the season is so eminently calculated to call forth. The Editor will not fail on his part, and will be glad to find a hearty response to this challenge to do mutual good.

THE MECHANIC'S EXCHANGE.

We again call the attention of our readers to the scheme for a "Mechanics' Exchange," contained in our last number. Hundreds of letters have come to hand, all praising the scheme, and some suggesting improvements in it. If the scheme is to be carried out it must be done thoroughly, and we await the opinion of the majority of our subscribers.

The English Mechanic.

FRIDAY, DECEMBER 15TH, 1865.

OUR TELEGRAPHIC INSTRUMENTS.

It has been deemed that the insertion of the following particulars, brief indeed, as to the merits of the principal telegraph instruments now in operation in this country—viz. the "Morse" and the "Bells," will prove interesting to some of our

readers, and tend to draw forth the opinions of those who have worked the various instruments, and who are therefore perhaps best qualified to speak as to their capabilities.

Much has been said and written in favour of both systems by those parties interested, both commercially and scientifically, but the object now is to endeavour to explain the actual rate of working, correctness, and general efficiency of the above-mentioned instruments, and as the Morse was the first of the two systems introduced to any extent in this country, priority is here given to it.

The Morse is principally used by the Electric and International and the United Kingdom Telegraph Companies. The instruments used by the latter differ slightly in construction from those of the former. One wire is required for the transmission of the signals, which are received, embossed, or printed in ink on a narrow strip of paper, and thus preserved for reference. By this means additional accuracy is guaranteed, as the clerk, when an unintelligible word is received is enabled to re-examine the signals; thus dispensing with the necessity in many cases of having the word repeated—an advantage not to be overlooked, as repetitions involve delay.

The average speed of working is 23 to 25 words per minute, with ordinary commercial messages, or, in sending speeches through, 30 words can easily be managed. Of course it must be understood these results are only obtainable when efficient clerks are employed.

With regard to the "Bell"—in operation in England, only on the lines of the British and Irish Magnetic Telegraph Company—it also requires only one wire, but the signals in this case are read off by sound from two bells of different tone. It will be obvious that some degree of skill is required on the part of the clerk, and as he is unable to refer to a slip, and has to keep up with the sending clerk, a single word unreadable gives him the option of stopping the sender at once or having it repeated at the end of the message—thus causing delay. But, to counterbalance this disadvantage, a speed of 50 words per minute can be obtained; the average rate being from 30 to 40. The last Queen's Speech was forwarded per this instrument at the rate of 48 words per minute.

* By these meagre but sufficient facts it will be seen the Morse is the most accurate—the bell giving the greatest rapidity. Which of the two advantages is the greatest, our readers can settle for themselves.

It should be mentioned that by an arrangement of the key used by the Electric Company, a wire in contact can be worked, whereas it would be useless with the bell system.

Our own opinion of the matter is, that taking them on their merits, they are each excellent in their way; and have no doubt that the bells, carefully worked with a careful, experienced attendant could produce as good results as the Morse—at the same rate of transmission.

ON THE ENGINEER'S SLIDE RULE.*

(Continued from page 113.)

The three principal forms in which materials present themselves to the artisan for measurement or weight are the cube, cylinder, and globe, consequently, the greater part of the tables on the Engineer's Slide Rule is devoted to the gauge points necessary for these purposes, hence we find three separate tables headed "square or cube," "cylinder," and "globe," and under these headings appear the F's and I's, which are simply contractions, for feet and inches.

The cube being a figure of three dimensions, viz.: length, breadth, and depth, and as those dimensions may be given all in feet, or all in inches, or partly in feet and inches, there are corresponding columns under this heading, giving "gauge points" to meet each case.

The cylinder has only two dimensions, viz.: diameter and length, and as the length is usually given in feet, and the diameter in inches, or occasionally both are given in inches, two columns only are devoted to this figure.

Lastly, the globe has only one dimension, viz.: diameter necessary for calculating its weight or cubical contents, yet two columns of gauge points are also required for this figure, since the diameter may be given in feet or inches.

The first line of gauge points under these respective figures is marked cubic inches, and is intended solely for measuring the cubical contents of bodies. Thus, if we had a piece of iron 1" long, 1" broad, and 1" thick, its solid content would be

* Contributed by Mr. W. Tenkes.

$1 \times 1 \times 1 = 1$; consequently, when the dimensions of a body are given all in inches, our gauge point is 1. But if the body had been 1 foot long, 1 inch broad, and 1 inch thick, it then would contain 12 cubic inches, since one of the dimensions had been increased 12 times, and hence, after we obtained the contents by the ordinary method we should have to multiply by 12, requiring a second operation whenever the dimensions were given partly in feet and partly in inches.

To avoid this double work we find a decimal equivalent by dividing 1 by 12, which gives .0083, and by dividing by this as a gauge point we perform the operation at once. So, also, when all the dimensions are given in feet, and we require to know the contents in cubic inches, instead of multiplying by 1,728, we use the divisor .000,578, the gauge point under F. F. F.

The next line of gauge points is for the solution of questions where the contents are required in cubic feet, hence, where the dimensions are given all in inches the result must be divided by 1,728, the number of cubic inches in a cubic foot, hence 1,728 becomes the gauge point, but when two dimensions are given in inches, and the third in feet, as in the second column, the result, as before, would be 12 times too small, hence our divisor or gauge point

1728

must be 12 times less, or $\frac{1728}{12} = 144$, and when the

12

dimensions are all in feet, the gauge point will of course be 1, or 1,728 times less than when inches only were used.

To find the gauge points for the cylinder it is necessary to consider that if a cylinder and cube are equal in length, their contents will bear the same proportion to each other as the areas of their cross sections, such sections being respectively the circle and square. It is well known that a circle, the diameter of which is 1, and a square, of which the side is also 1, bear nearly the same ratio to each other superficially as .7854 to 1, hence if we divide the gauge point of the cube where the dimensions

1

are given in inches by .7854, we get $\frac{1}{.7854} = 1.273$,

.7854

the gauge point for the cylinder when diameter and length are in inches, and this result divided again by 12 for the reason already stated, gives

1.273

$\frac{1.273}{12} = .106$, the gauge point when the diameter is

12

in inches, and the length in feet, and in like manner we could, if necessary, obtain the gauge point when the answer is required in cubic feet.

Again, it can be shown with regard to the globe that it bears very nearly the same proportion to a cube when the diameter of the one is equal to the side of the other, as .5236 : 1, and therefore, by the same process as with the cylinder, but using .5236 as a division, the gauge points for the contents of globes are determined.

The next point for consideration is the capacity of vessels, or the quantity such vessels would contain, the standard being the imperial gallon, which approximately contains 277 cubic inches, consequently, when the dimensions of the vessel under consideration are given all in inches, the gauge point is 277, and precisely the same rule as above given holds good for finding the other gauge points when the dimensions vary in kind or the vessel varies in form, whether cubical, cylindrical, or globular.

The other gauge points given in the three tables above referred to are designed for the purpose of finding the weight of bodies when the dimensions are given, those in the column III. being a table of the approximate number of cubic inches in a pound of the different materials named. Thus one pound of water contains very nearly 27.65 cubic inches, while one pound of copper contains 3.12 cubic inches, and so on with the others, and, as shown in the case of mensuration, all the other columns are deduced from this one by using the proper divisors.

It is evident that if we can by any means find the number of cubic inches in any body placed before us, and if we also know how many of those cubic inches of the material are contained in a pound by weight, by simply dividing the contents by this latter number, we at once find the total weight of the body, and this is just what we do when we attempt to find the weight instrumentally by means of our rule, and having the four lines of numbers and the proper gauge points, we are enabled in one operation to find the solid contents and the weight of the body when its form is either a cube, a cylinder, or a globe, thereby reducing rather a complex series of mathematical manipulations to one of the greatest simplicity. In cases of irregular figures a preliminary operation will reduce them to one of the

three forms above enumerated, when the given rules become applicable, and practically these irregularities occur most frequently in figures of square section, the breadth very often exceeding the depth, such however, can with great ease be reduced to a mean square by the rule given for the "square and its root." In dealing then with the mensuration of solids, whether we require to find their solid contents, their fluid capacity, or their weight, one general rule holds good, and that is as follows:—All gauge points must be found on A, and placed against the length of the bodies found on B, then if the body be a regular figure, find the side of cube or diameter of cylinder or globe, but if irregular find the mean square or diameter on D, against which is found on C the cubic contents, fluid capacity, or weight, according to the nature of the question and the gauge point selected.

As an example, suppose we required the weight of a cast iron pillar, 10 feet high, and 10 inches diameter?

For cast iron in the column of cylinders under feet and inches (F. I.) we find the gauge point .407, and setting this number upon A, against the length, 10 feet on B, against the diameter 10" on D, we find the weight required, viz : 2,450 lbs on C.

To obtain this result arithmetically we should

 $10 \times 10 \times .7854 \times 10 \times 12$

have to operate thus: $\frac{10 \times 10 \times .7854 \times 10 \times 12}{.407} = 2450$

3.84

somewhat tedious operation, which would give as a result 2,459lb., or 9lb. more than obtained by the rule, a difference practically inappreciable, and arising not from any inaccuracy in the principle upon which the rule is founded, but from the infinitely small divisions that would have to be made in its construction in order to give the exact fourth figure, it is, in fact, a sacrifice of extreme accuracy to great simplicity and speed of manipulation, readily accepted as sufficiently close an approximation to suit all practical purposes.

(To be continued.)

MECHANICAL EQUIVALENT OF LIGHT.

For some time past it has been considered certain that light is capable of producing mechanical effect; but the relative amount of the latter was not hitherto determined. We have now, however, obtained the desired information on this point, by means of the researches of Professor Thomsen, of Copenhagen. He changed the light into heat, and then estimated the mechanical effect which the heat was capable of producing.

For this purpose he caused a beam of light, freed from all caloric rays, by transmission through a layer of water, to pass to a thermo-pile; and the heating effect thus produced was determined by the deflection of the multiplier.

During these experiments, various modifying circumstances were to be taken into account; thus, the absorption of luminous rays by the water was found to be 0.13, and this was to be allowed for. The indications of the thermo-multiplier were compared with the absolute radiation of heat, and it was ascertained that only one-seventh of the entire heat disengaged leaves the flame as radiant heat and light, the remaining six-sevenths being carried away by the heated air; but the more intense the light, the greater the radiation.

The conclusion arrived at was, that a flame whose luminous intensity is equal to that of a candle which burns 126.5588 grs of spermaceti per hour, radiates, per minute, light which, changed into heat, would raise the temperature of 63.28 grs. of water 1.8° Fahr.; and that light, whose luminous intensity is 34.9 times as great as that of the spermaceti candle, would raise 15.434 grs., or about 2 lbs. 3½ oz. avoird., one metre (39.37 in.) high in a second—that is, would perform a unit of work.

The experiments were made with the light obtained from a spermaceti candle, a gas flame, and a modérateur lamp. Solar and electric light have not yet been examined.

Some curious calculations have been founded on the above results. Taking the total light of the sun as equal to 1,230 septillions of spermaceti candles, and that it would produce proportional effects, it would lift a weight equal to that of the earth twenty feet per second.

SUPPOSING the motion of the earth on its orbit were stopped, an amount of heat would be developed sufficient to raise the temperature of a globe of lead of the same size as the earth 384,000 degrees of the Centigrade thermometer, or, in other words, the heat thus raised would be equal to that derived from the combustion of 14 globes of coal, each equal to the earth in size.

PETROLEUM AND ITS PRODUCTS.

In the treatment of petroleum almost every part of it is brought into a merchantile condition, even the residuum, or coke, which remains after the various oil and gases have been obtained is turned to account for fuel, being frequently used to carry on the several chemical processes to which the crude petroleum is submitted. The products obtained are—benzine or naphtha, burning oil, paraffin, and the coke. The naphtha, which is the lighter element, being something between a gas and a fluid, is driven off from 90° to 300° of heat, and constitutes about 15 per cent. in bulk of the crude oil. The lighter naphtha is now called gasoline, and from it an illuminating gas is prepared. The warmth of the hand will cause it to boil. A heavier distillation is used for cleaning purposes, and a still heavier has been used by painters as a substitute for spirit of turpentine. At from 300° to 500° the product of the still is a light oil, which, after treating with sulphuric acid and caustic soda, for the purpose of deodorising it, becomes the burning oil of commerce. This constitutes about 60 per cent. of the crude oil. As the heat is gradually increased from 500° to 800° heavy oil is produced, which, being treated in the same manner as the burning oil, is then barrelled up, and packed away in the cellar, with ice and salt, for the purpose of chilling it, as it is called. This is effected shortly, when, upon opening the barrels, the oil is found to have assumed something of the appearance of calves-foot jelly. It is then put into canvas bags, and being placed under a screw press, is subjected to an immense pressure. The finished lubricating oil is thus squeezed out, and separated from the paraffin, which is found in the bags in the shape of thin white cakes, which are almost perfectly tasteless, and in every respect resembling wax. This being purified, is used for the purpose to which common wax is applied, such as the making of wax candles, clear starching, the manufacture of chewing gum, &c. In its refined state this paraffin is worth from 20c. to 35c. per pound. The lubricating oil will, perhaps, make 9 to 10 per cent. of the amount of crude from which it is distilled. The paraffin may equal 1 per cent. At 800° the contents of the still will show a red heat. The distillation is then stopped, and the residuum, which is a sort of coke, similar in appearance to ordinary coal coke, is removed, and used for fuel.

LETTERS TO THE EDITOR.

(We do not hold ourselves responsible for the opinions of our correspondents.)

HOW GREAT COMPANIES REMUNERATE THEIR OFFICIALS.

Sir,—Your out spoken article upon the Corporation gas scheme is worthy of you. I for one wish there was a little more competition in other companies—it might be the means of some of the underpaid officials being better remunerated for their services. You may better understand me when I inform you that I am intimate with the manager of a department in a wealthy company paying 8 per cent. and a heavy bonus, free of all income-tax, and a fund of £50,000 of undivided funds, and although the directors, auditors, &c., know that this man has four children, his salary is only £26 per annum, the profits of his department are £9,000 per quarter, deducting £1,000 per annum for all working expenses. CRUC.

VELOCIPEDES.

Sir,—I have just seen your article on "Velocipedes," and wish your correspondents had sent in something of greater novelty in mechanism.

Now, Sir, being an amateur in this line, and having plenty of advantages to try anything I might wish, I beg to offer you my experience.

About twelve or fourteen years ago a friend of mine used to amuse himself with one of the old-fashioned dandy carriages with one crank and one handle. About eighteen months ago I looked it up, but it was too rude a machine to go at any speed; so I set about making one to carry one person upon the principle you explain in your valuable paper. But, alas, it would not work—scarcely able to move along a level road. I took it to pieces, and re-constructed it according to my own idea, and for two persons. When finished, we attained a speed of about six or seven miles an hour, but could not get up hill. Well, about six months ago, a postman between a village about six miles from Leicester, bought one called the "American Lever Pendulum Carriage." Mine then sank into oblivion against his, so I set about to put some parts to mine resembling in principle what seemed to me to be the secret of his. At last, about two months ago, I got it work. I also enlarged it to carry three, all working with both hands and feet, and I think it as near perfection in a velocipede as possible. With the roads dry we can attain a speed of ten to twelve miles an hour, and ascend ordinary hills with ease. It also carries two as easily and comfortably as three. There is a lock-up box on it to carry tools, &c., and some day I mean to undertake some long journey in it with a couple of friends. It works quite to my satisfaction, and, if desirable to you, I will send a description of it. SCHWILLING.

[We shall be glad to receive the description with drawings.—Ed. E. M.]

DISC SHOT CANNON.

Sir.—Reading of the number of improvements that are being effected in fire-arms, I venture to send you a design which I think is quite novel, and possesses some advantages over others; the design I send you is that of a cannon and shot, which I term the disc shot cannon.

Fig. 1 is the plan view of the cannon; figs. 2 is the side elevation; figs. 3 and 4 are end views, and figs. 5, 6, 7, 8, are views of the shot.

The advantage which I think is in my plan is increased penetration; as you will observe in the shot that it is flattened, and that it has a very thin outting edge, so that in rotating any object which comes in its way will receive the sharp edge, which would, according to my ideas, penetrate farther than those at present; the rotating shot, figs. 5 and 6, would receive rotation either by having the bore made deeper at one side than the other, or the shot could have indentations at the sides, as shown in figs. 5 and 6, so that the air would act against them and cause the shot to rotate; and the greater the rotation, the greater the penetration; as a piece of soft iron rotating at a very great speed has been known to cut through a hardened file, so that I am of opinion that my shot would produce more effect than a rifled one, as it would then act as a saw and wedge; of course on entering the material the rotation would be diminished, but then we must look at the rifled shot, they rotate and see the penetration which is due to their rotation.

I do not confine myself strictly to the shape of the shot and bore I send, as the shot may be quite flat and rounded or sharpened at its edges, or like a ring, hollow in the middle. Figs. 7 and 8 is another sort of shot; not rotating shots. The cannons could be made either with the widest part of the bore horizontal, vertical, or at any angle; it would be rather difficult to bore the cannons at first, as some alterations in the present machines would be requisite.

This is not the first time I have had the pleasure of sending designs to you for publication, as I sent a railway break to you which you kindly published in your paper of June 30th, of the present year; I therefore hope you will oblige me by publishing this, as I have other designs I should like to send you, which may prove very interesting to your numerous readers, and of course open to improvement, as there is room for improvement in everything. I must conclude, hoping you will oblige me by publishing this design.

CHRISTOPHER JAMES LITTLE.

CORRECTION.

Sir.—In your impression of the 1st inst, you inserted five theorems from me on the safety-valve lever, three of which the arithmetic sines were not correct.

$$\begin{aligned} \text{1st. You have } \frac{a \times c}{b} \times c \times e &= d; \text{ which should be } \\ \frac{a \times c}{b} + c + e &= d \dots (1) \\ \text{2nd, } d - c - \frac{(a \times b)}{b} &= e; \text{ which should be } d - c - \frac{(a + b)}{b} \\ &= e \dots (2) \\ \text{3rd, } b - \frac{(d - c)}{a \times b} &= c; \text{ which should be } b - \frac{(d - c)}{a + b} = c \\ \dots (3) \end{aligned}$$

J. S.

OUR SUBSCRIBERS' NOTES AND QUIRIES.

OVAL CHUCK.—Never having seen drawings before of your oval and eccentric chucks for turning, nor any kind of those working apparatus, I must own I cannot thoroughly understand them. Would your correspondents

kindly inform me if that kind of chuck can be applied to a common lathe, with face plate and back gear, driven by the foot? If so, how they are connected to the lathe spindle or face plate, their mode of operation and working, how to chuck the work to be turned, and if it can be turned by a hand tool, either in wood or iron; also, if the centres of the lathe have to perform any part in the work? Any information would be kindly accepted.—SYSTEMATIC.

LATHES MANDREL.—Can any correspondent assist me in a little difficulty? The mandrel of my lathe binds in the collar, and I cannot tell the reason. Both mandrel and collar are steel, both hard, and fitted as well as any I ever saw, and yet even when well supplied with oil, after turning some time, they heat and bind. Any explanation of the difficulty will be greatly esteemed by—A TURNER.

DRILL.—Will Mr. W. H. Northcott or any gentleman inform me of the kind of drill or rimer used for re-boring gun barrels that are out of truth by long use and rust, and the manner in which such operations are performed?—CINA.

SILVERING.—Can any of your readers inform me how small articles of brass or iron may be coated with tin to have the appearance of silver plate?—HIND'S HEART.

BOILER.—Can any correspondent furnish me with some idea of the most suitable sort of boiler to drive a small steam engine about two horse-power on board of a small pleasure boat, particular attention being paid as regards cheapness, usefulness, easy and little firing, and capable of rising steam quickly and retaining same, as, also to be in as little bulk as possible?—NAB.

MAGIC LANTERN.—Will some correspondent inform me the cheapest and best way to construct a magic lantern of sufficient size for a lecture room, to form a disc, say, six or eight feet diameter; also, the sort of lenses, their diameter and length of focus, also the best light to use, and how made.—W. SALE.

REMOVING VARNISH.—Can any contributor tell me of

give me the proper address of the Paraffin Oil Works or Oil Refinery at Chester? W. H. H.

COMPOSITION SAW DUST.—Can any of your readers inform me how to make composition saw-dust, such as is sometimes used to make malleability?—TOS. WOOD.

MELTING BRASS AND COLOURING G.D.—Can any reader answer the following questions:—1. When I melt brass by means of the furnace described in No. 28 of THE ENGLISH MECHANIC, the melted metal does not pour well; how can I make it run easily into the small moulds which I use, so that it will not run out in a thick heavy mass? 2. How is 18 carat gold coloured?—MILLA NICK-SACK.

HARDENING STEEL.—Many thanks to the several correspondents who so kindly answered my enquiry for screw threads. For the information of novices like myself, I beg to record the following:—I tried to harden two pieces of steel in a domestic fire, and failed. I used the bellows, which made matters worse, the fire outgassing the iron. I thought it probable that the blast impinging on the steel abstracted some of the carbon, similar to the Bessemer furnace. I tried again, by placing the steel in the fire above the blast. I blew it very hot, taking care, by noticing the colour of the fire round the tool, that the cold blast did not touch the steel. I succeeded with best results—the steel seemed to absorb fresh carbon from the fire. Perhaps some of your practical correspondents can throw some light on this point?—ARROW.

GALVANISING.—Will any reader inform me of the best and cheapest apparatus for galvanising iron hoopings in bars?—A COPPER.

WATER GAUGE.—If the glass tube of a water gauge, or a steam gauge be cleaned out with a wire, even when the tube is quite cold, it is sure to break in some hours afterwards. I should be glad to know from some of your correspondents the cause of this.—BRITTLA.

JAPANNING, &c.—Will any subscriber inform me how to Japan iron for parlour ornaments, the materials of which it is composed, and the best method of using it? Also, the best form, cylindrical or spherical, of a copper boiler, to hold about eight gallons for a working pressure of about 25 lbs., the best method of making it, and the price?—MORGAN.

FRET SAW.—I should esteem it a favour if Thos. Merritt would furnish the following information respecting the fret machine as inserted in a recent number, where it can be procured, the probable cost, if driven by hand or steam power, and the force required, and if he would grant a personal interview?—JOHN HERRICK.

BROMING.—Can any correspondent inform me of a good way of broming medals?—B. KINGSLAND.

GERMAN YEAST.—Will any reader of THE ENGLISH MECHANIC kindly inform me how to make quick German yeast, such as is imported from Germany?—BAXER.

VELOCIPEDES.—Will any reader kindly inform me which is the proper kind of teak, and where to obtain the best felling for velocipedes?—N. J. W.

ATLANTIC CABLE.—What amount of pressure is there on a foot or square inch of, say, the Atlantic Cable? what pressure does it sustain at 30 feet under the surface, 100 feet, 1,000 feet, and one mile?—MAGNET.

ENGINE VERSUS WATER WHEEL.—Will a 10-horse engine cylinder consume as much steam as a 10 horse-power water wheel consumes of water? or, rather, perhaps, would the same quantity that turns the water-wheel be the same as would work an engine of the same power?—MAGNET.

REPLIES TO QUERIES.

THE PLANETS AND CHEAP TELESCOPES.—It would be absolutely impossible to answer your correspondent, Mr. C. T. Whitwell, without encroaching exceedingly on your space. I may, however, just say that for the planets to describe circles round the sun the force with which each was originally projected must have been precisely equivalent to the velocity which it would have acquired by falling through half the radius of the circle. The great improbability of this exact coincidence will be at once seen; and any deviation from it necessitates the description of an ellipse by a planetary body; or, in an extreme case (as that of a comet), where the projectile force preponderates much over the attraction of the sun, of a parabola, or even a hyperbola. I am, of course, ignorant of the amount of Mr. Whitwell's mathematical knowledge, and have, therefore, some diffidence in referring him to sources of information; but I should think that consultation either of Tomlinson's "Mechanics" (part 3, sec. 3), or of Maie's "Astronomy" (chap. 4), would suffice for his purpose. I mention these books on account of their cheapness; they only cost a shilling each and are published in Weldon's series. One word as to cheap telescopes. All the directions sent by your correspondents are merely what is called at Cambridge "crib" from the works of the late Dr. Dick. I well remembered the 36 inch and 1 inch convex lenses, when I cautioned Athelstan against a non-achromatic object glass. Should he and Magnetifer however, determine each to construct one of these fearful and wonderful instruments, I can only recommend them to try and attain the frame of mind of the man in Punch, who went for four ounces of mixed tea; and who while he "hoped for the best, was prepared for the worst."—A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.

In reply to C. B. M. S. I know of no such rule as that he enquires for, nor until some new method of proportion is discovered, wherein, with two numbers given to find the remaining two in order to complete the proportion by a single operation, is it very probable that such rule will be found. A range at leisure through the fifth book of Euclid would be of service to C. B. M. S. Ebonite discs, already prepared, and with finely polished surfaces, can be obtained of Messrs. Silver, the patentees, Bishopsgate street, London. Price about 4s. per weight. For the cushion of mine I use common wa-h leather and the usual amalgam, same as applied to glass discs. My plate 14" diameter x 1" thick weighs about 1½ lbs. as nearly as I can remember.

I think Theo. can buy a disc ready turned cheaper than buying sheet ebonite to construct one, and very much

some means for removing the varnish called oak stain from timber without scraping or staining the wood, as potash does? Also, the best composition with which to paint the masts and spars of a yacht after having been scraped?—YOUNG YACHTSMAN.

CASTING.—Can any correspondent inform me of a first class mixture of metal for casting steam-engine cylinders?—BRISTOL.

SILVERING STEEL.—Can any reader inform me, first, the process of bluing without heat; second, of bluing steel without heat?—C. K. L.

ADDRESS WANTED.—J. K. wishes for the address of Mr. S. Taylor, whose letter on the Atlantic Telegraph Cable appeared in THE MECHANIC in June last.

CORNISH ENGINES.—Can any reader inform me where I can procure, in a cheap form, a description of the Cornish engine, with illustrations, such as used in the various London water works companies? I am the inventor of a low pressure ball cock, and should be glad to dispose of it, or join some really honest person in bringing it out. Its merits are, first, that it is effectual; second, it is very cheap; third, it is not worth stealing; fourth, it cannot easily get out of order, and if it does a child could repair it.—A. N.

METALLIC PAPER.—How is this paper (which is used for pocket-books) prepared, and of what metal are the points for writing upon the same made?—Z. Y. X.

CIRCULAR SAW.—I have had a circular saw frame (foot power), ten years for cutting Jacquard rags used in lace machinery, but cannot make it cut more than 3 inch thick to work comfortably. Beyond that, it becomes labour, and the power ought to be steam, or does Mr. A. Lee think the panel saw preferable?—BURT JOINT.

FRET SAW.—Will Thos. E. Merritt oblige me through your journal with a few figured details of his fret saw, and the thickness it will cut hard wood, and oblige.—BURT JOINT.

OIL WORKS.—Will any of your kind Chester readers

chamber than a glass one, with the advantage of far higher insulation and no liability to fracture. In fact, in all cases where it is applicable in the construction of any electrical apparatus we may say without flattering the inventor, "there's nothing like glass."

J. C. Wigg. I believe there is not even an empirical law yet formed for determining the length and thickness of wire for the electro magnet in such machines, almost every maker varying in accordance with his opinion, and the purpose for which the machine is designed, from the simple medical toy up to Hixington's electro plating, and beyond that to Prof. Holmes' electric light machines.

What you have to bear in mind is that you are dealing with "high tension electricity," to which well insulated copper wire, however fine or long, offers but slight resistance, while every additional turn increases the extent of your effects up to a certain point, which experiment with your machine alone can determine.

Oh mamma, you can readily deposit iron on gutta percha, using a solution of sulphate of iron, with a plate of iron as a cathode. The moulds must be well and evenly covered with plumbago, for which purpose gutta percha is eminently fitted. Use Daniel's battery, and increase the tension as may be found necessary.

Vincent O. Davis. In coupling for quantity, you join up all the carbon plate terminals to each other, to form one pole of your battery, and all the zinc plates in like manner to constitute the other pole. But in doing so, you affect something which hitherto you have most probably overlooked, viz.: decreased the tension of your current three times, hence if you use the same external resistance (the wire which conveys the current from and to the battery), you will certainly find that you get less quantity than when you had the arrangement for tension. While, if instead of using the same wires you substitute very short and rather thick terminals, you then find the advantage (for certain purposes only, mind) in altering to quantity. I regret, that in consequence of the limited space at the command of the Editor, I can only supply you with bare facts without a rationale, but since we are promised a "double number at Christmas," I may, if time permits, revert again to this and kindred subjects.—**WM. TONKES.**

BOILER CONSTRUCTION.—I am sorry that Aspirant does not understand the system of my boiler. Its principle combines a mode for preventing urrowing, and adding strength to the boiler without increasing the weight to any great extent. There have been several theories offered on the corrosion of steam boilers; one of these is, that carbonate of lime decomposed from the feed water by the heat, is forced by the pressure and the current into the expanded seams, these attempting to return to their original positions, are opposed and resisted by minute particles of this destructive agent, which, on account of its great hardness, is enabled to cut, and thereby destroy with great facility the fibres of the plates. The theory, however, to which I am inclined to give the preference, is, that chemicals derived from the water lodge on the edges of the plates and seams, causing a galvanic action, thereby destroying the plates.

Taking this into consideration I saw that if a boiler could be so designed that there would be no lodgment whatever for these chemicals, and that if the plates did corrode they could not give way of themselves; and, when they did give way, they would have given ample warning beforehand—that such a boiler would be a great improvement. Some time after I designed the boiler, the merits of which are at present under review; and an attentive examination of the drawings will show that it possesses all the above merits. The edges of the plate meeting flush, unless the boiler expands to an unusual amount, there will be no lodgment for any of these agents; then (looking at the figures 4 and 5), if by any un-looked for manner the plates corroded, the joints would leak to such an extent long before there would be any danger, that the attendant could not help noticing the leakage. The strength of the boiler does not depend on the plates and riveting alone. The strain of the plates being thrown on the riveting and flange plates; as these latter cannot give way without withdrawing the wedges on their ends, the wedges must be crushed, and throwing the strain on the hoops, burst them before the plate could give way.

I hope that Aspirant and others will fully understand the above explanation, and shall now proceed to Aspirant's letter of Nov 24th. I disavow that Aspirant fully understands the method of calculating the strength of bottom, and likewise of steel hoops subjected to strain, in which case he will perceive that the strength "the hoops would only add" will be according to the area of their cross section in their weakest part. Aspirant prefers thick plates for the boiler, and dispensing with the hoops, his experience may have taught him to do so, I will therefore show him some of my objections. Boiler plates diminish in their tenacity after they have been heated to a certain temperature (550°); passing that point they begin to diminish very rapidly till they arrive at the temperature of 1,200°, when the tensile strength has fallen to about 1/1000 the per square inch of section. An accidental overheating will have the same effect, but to a greater degree. Iron increases in weight to its strength in a greater proportion than steel.

One of Aspirant's objections to riveting is the fact that punching the rivet holes will injure the plates. As such is the case, why does he recommend thicker plates? The punching will injure them to a greater degree than it would the thin ones; if he drilled them it would take a longer time, and heavier machinery; were he to weld them it would take more labour and there would be a greater certainty of a deficient joint. For these reasons, I should recommend him to use thin plates whenever it is possible; to drill his holes with such a drill as is used by most engineers of the present day, which will drill from 6 to 23 holes at the same time.

I shall not notice Mr. Jenkins' letter, beyond thanking him for his complimentary opinion and conclude by informing him that the system he recommends is exceedingly like a system, patented by Mr. Galloway, introduced some

years ago, and that, if I employed tubes "of a little less substance," that it would obstruct the passage of the hot air and smoke, that I doubt if it would produce a sufficient blast; nevertheless, he will doubtless hear of me some day at the Masuro Boiler Works, with due thanks for his kind invitation.—**ADRIAN NEWSON.**

MAGNETS' CONSTRUCTION.—In reply to F. Donnelly. It is essential that the springs B, R, in my sketch of a magnet machine be brought in metallic communication with the terminals T, T. The dimensions of the steel magnet are as follows:—10 inches high, 2 1/2 inches in breadth, by 3 in d. ph. If expense is an object, a horse-shoe magnet of the dimensions given, made of cast iron and magnetized in the usual way will form a good substitute for the steel magnet, and if not quite so effective is considerably cheaper.

F. R. S. A. It is a difficult matter to entirely destroy the influence of a magnet on an object at short distance off, by inserting a substance between them. If it is merely wished to partially destroy this influence, it may readily be done by inserting a soft iron armature between the two; the closer the armature to the magnet, the less will be its influence on the object.

A. H. V. and Wm. Gibson will find the condenser described in No 20 of THE ENGLISH MECHANIC attached to the contract breaker of induction coil or magnet in following manner. Solder or otherwise fasten a piece of wire to each side of contact breaker, selecting the most convenient part for that purpose. The opposite ends of these two wires should be soldered to a couple of thin discs of copper (about the size of a penny piece, but much thinner), the surfaces of which ought to be well tinned. Finally, bring one of these discs of metal in contact with the sheet of foil forming one end of condenser, and the other disc to the sheet of foil forming the opposite end or side of condenser. The discs of metal are kept in their respective places by pressure. Single sheets of tinfoil may sometimes be purchased at an operative chemist's at 2d. per sheet. Tinsmiths generally sell it by the pound. 2s. 9d. is about the price.

C. C. You can obtain sheets of India rubber either at Silver's Bishop gate-street, or at Macintosh and Co., Cheap-side.—**EDWIN FURZE.**

PRESSURE ON VALVE.—In reply to your correspondent J. M. S. I beg to state that the pressure upon the valve (per his sketch), will be as follows:—

The lever being of the second kind, the effective weight of which will be equal to $6\frac{1}{2} (2' 14\frac{1}{2}) = 19' 15 11.16 = 19.9604$, and by a known property,

$$33 \times 9\frac{1}{2} + 19.9604 = 160.1158 = \text{weight upon valve.}$$

Now the area of the valve = 2.4053 square inches, 163.1158

$$\frac{163.1158}{2.4053} = 69.062 \text{ lbs. pressure per square inch, as required.}$$

The answer to the second question is as follows:—

$$60 (2.4.65) - 1.4373 = 144.808 \text{ lbs effective pressure on lever. Now let } x \text{ be the distance from the fulcrum required.}$$

$$\text{Then } 33x + 19.9604 = 2 (144.808) \\ 3 (14.8836) - 19.9604$$

$$\text{Whence } x = \frac{20.8872}{3} = 6.9624.$$

The distance from the fulcrum is therefore 6.1-16" inches I trust this will meet the requirements of your correspondent.—**JAMES J. A. FLOWERS.**

OIL FOR CLOCKS.—Seeing a correspondent wishes for a receipt, I beg to offer one I have found very good. It is to take about ounces of the best sperm oil, put in it about 2 teaspoonfuls of ordinary carbonate of soda; warm it slightly and shake as much as you like. Then set it aside for a week or so to settle. Use of course the clear oil from the surface. This process removes all acid from the oil, which will otherwise turn the brass &c. green. For ordinary purposes good sperm oil is better than any other, as it does not get hard and sticky.—**A. H.**

TO SUPPLY CAST IRON.—If picking in dilute nitric acid does not answer, place the article in a clear fire, and heat it to a dull red for half an hour. It must not get too hot, or it will crumble up when pulled out. Then let it cool as slowly as possible. If the heat be a bright red, owing to the extreme brittleness of cast iron at that heat; it will almost certainly break. At least, that has been my unhappy experience over a clock wheel.—**SCHOOL OF MINE.**

STEAM VALVE.—J. M. S. will find the following a correct answer to his query on pressure on steam valve in No. 35. When the valve is loaded as in the sketch, steam will begin to blow off at 6.19 lbs per square inch.

The weight should be placed 8.128 inches from centre of fulcrum or point pin, to obtain a pressure of 6) lbs per square inch on boiler.—**W. H. J. P.**

ASTRONOMY.

Sir,—I am pleased to see by the pages of your valuable work that an interesting and ennobling branch of science, viz: astronomy, is the subject of inquiries from numerous correspondents.

Mr. E. B. Wegg has given instructions how to make an astronomical telescope for £2 10s., an instrument at such a price very few "English mechanics" could buy or make. If you will allow me the space for the following description and diagrams, I will endeavour to instruct those readers who are interested in the subject how to make a telescope which will show the satellite of Jupiter, the rings of Saturn, the mountains and valleys in the moon, at the cost of a few shillings. First, we require two lenses, diagram below illustrates the kind, for an astronomical telescope; they are called double convex.

The object glass is the large lens placed at the end farthest from the eye; the most convenient kind is 48 inches in focal length, the price 3s. 6d.; the eye glass is the one nearest the eye, its focal length should be 1 inch. Price 1s. The two will produce a magnifying power of 48 times.

The tube can be made of brown paper, or you can have it made by a tinman for a small sum. If you intend to make it of brown paper, commence by pasting sheets round a roller 42 inches in length, 3 1/2 inches in diameter, let each layer dry before you paste the other on; now into one end fix your object glass, commence making tube No. 2. It must be 8 inches in length and must just slip into tube No. 1; in one end fix your eye glass, then slip one tube into the other so that it can be drawn in and out at pleasure. It will be necessary to provide a cap with a hole about 1/4 an inch in its centre, to slip on the smaller tube, and to which the eye is placed. It may be as well to mention that in looking at some objects, it is necessary to contract the aperture, this may be done by means of a piece of card perforated with holes of different sizes. If your telescope is made correctly it will be like the following diagram.

A, object glass; B, long tube; C, the cap; D, eye-glass E, small tube. **ED. MCGURK.**

SUN AND PLANET MOTION.

Sir,—In answer to C. W. (Peterboro'), I send a drawing and description of Watt's sun and planet motion.

It may be seen at a glance that the sun and planet wheels are only a concealed crank. (It is said that Watt invented the real crank as it is now in use; but that a workman left his employ and divulged his invention to another man, who immediately produced a crank on Watt's plan, but took the credit of the invention to himself.) Watt was obliged to invent this motion to render his engine complete without any other person's production.

A is the beam; B, the connecting rod; C, the fly-wheel; D, the sun wheel; E, the planet wheel, and F, a bar of iron connecting the centres of the sun and planet wheels.

On the axis of the fly wheel, C, is fastened a small concentric toothed wheel, D; a similar toothed wheel, E, is fastened to the connecting rod B, (which comes from the end of the beam), so that it cannot turn on its axis, but must rise and fall with the motion of the beam.

A bar of iron, F, connects the centres of the two small toothed wheels, D and E, when therefore the beam raises the wheel E, it must move round the circumference of the wheel D, and with it turn the fly-wheel C, which ought to make two revolutions while the wheel E, goes round it once; thus D, like the sun, turns only on its axis, and is consequently called the sun wheel, while E revolves about it as the planets revolve round the sun, and is, for this reason, called the planet wheel.

DAVID SLOAN THOMSON.

The number of locomotives on the railways of Great Britain, at the close of 1864, was 7,203: while at the close of 1863 it was only 6,643. To the increase of 560 here disclosed, England and Wales contributed 361; Scotland, 168; and Ireland, 31. At the close of last year English and Welsh railways had 5,708 locomotives between them; Scotch railways, 1,072; and Irish railways, 423.

HUMBOLDT stated that guano is deposited in layers of 50 feet to 60 feet thick on the granite of many of the South Sea islands of the coast of Peru. During 300 years the layer of guano deposited is only a few lines in thickness. This shows how great must have been the number of birds, and how many centuries must have elapsed to form the present guano beds.

THE ROYAL OBSERVATORY AT GREENWICH.*

In the long course of experience gained since the first day of the establishment of the Royal Observatory at Greenwich, the astronomical apparatus at that institution has reached a very high state of perfection. The work that is daily executed at the Observatory has for its object the mapping, with the greatest accuracy possible, the places of the fixed stars, so as to obtain zero points in the heaven with which to compare the positions of the moveable planets. These points of reference are of the greatest use to navigators, who require reliable information as to the position of the brighter fixed stars on given dates, which positions can now be determined at the Observatory many years beforehand with very considerable accuracy. The position of the moon also, is calculated with the greatest care. From time to time the observations taken at Greenwich find their way into the *Nautical Almanac*, in which the alterations are not made at one, but every few years, when the discrepancy between the two becomes too great, so that ultimately all the figures in the *Nautical Almanac* are founded on the Greenwich observations. The deductions also are used to correct the solar tables, and the observations of the moon at Greenwich are employed to compare with and test the accuracy of the tables of Hansen.

The principal instruments at the Observatory are the great transit circle, the altazimuth, the zenith tube, and the great equatorial telescope.

The great transit circle was designed by the Astronomer Royal, Professor B. G. Airy, and the engineer's work was planned by Mr. May, of the firm of Ransomes and May, afterwards Ransomes and Sims. Mr. May first suggested the cast iron tube of the instrument, and the object glass was ground by Mr. Simms the optician. The instrument is supported on two massive stone piers pierced with a few holes for the reading microscopes, and built up from a deep firm foundation in the earth, in order to avoid vibration. The roof overhead has four shutters along its ridge, easily opened by the mechanical appliances in the room. The tube of the telescope is rather less than 12ft long, and has an object glass 8in. in diameter. The tube is supported on an axis consisting of two pivots and cones, each pivot being cast in one piece with its cone, but not under similar circumstances. It was necessary, to ensure accuracy, that the pivots should be of very hard metal, and very truly turned. The mould for the pivot was made of iron, to chill and harden the metal, whilst that of the cone was made of sand. By this process pivots were obtained nearly as hard as steel, being afterwards shaped and polished with emery, with the same care as in grinding glass for a lens. The length of the axis of the telescope between the ends of the two pivots is 6ft. The pivots are 6in. in diameter, and in order to test their accuracy from time to time, they are perforated and a plate with a very small hole through its centre is fixed on the eastern pivot. In the hollow of its focal length from the plate, a lens is fixed, the collimator thus formed being viewed when desired by a telescope of 7ft. focal length. As yet no error has been discovered in the form of the pivots by this rigid test.

The flexure of the cast iron tube as attached to its axis has to be tested occasionally. This was done soon after it was first erected by placing an object glass in the centre of the tube and fixing a cross of wires at the object end, so that the image of them should be formed at the eye-piece. The telescope was then placed in a horizontal position, with its object end north and the place of the image at the eye end measured with the declination micrometer. The telescope was next turned over till it rested in a horizontal position pointing south, and the place of the image again measured. In two readings, taken in 1850 the difference was 0r. .204, 0'00414 inch, one-half of which, or 0'00207 of which was the effect of

flexure, a variation of no practical importance. The flexure is now regularly noted from time to time, by a process hereafter described.

The meridian of Greenwich, as stated in school books, is an imaginary line, passing through Greenwich from the north to the south pole; and by noting the instant that fixed stars cross this line, Greenwich time is obtained. Unfortunately the line is imaginary, hence the difficulty of ascertaining exactly when the stars cross it, so one by one the astronomer has to eliminate the sources of error. He, however, can easily find the zenith, also the 'centre of the small orbit described by the north star; so, should he first point his telescope to the zenith, and then depress it till he sees the north star, the telescope will have described a segment of circle in the true meridian of Greenwich. On looking through the telescope a number of fine vertical wires are seen crossing its field of view, the central one in the axis of the telescope representing the meridian; so, were the whole of the apparatus perfect, every time a star passes

exactly in the meridian, the astronomer could first point his transit tube to the south wire, and make its image fall upon the central micrometer wire by adjusting the latter, and then, on turning the tube over, if he found the north wire also coincide with the micrometer wire, he would know that he had the true optical axis of his telescope marked by the wire representing the meridian.

Two fine wires, however, cannot be fixed in those positions a few miles on each side of the Observatory, or if so fixed could not be seen when wanted. If they were fixed in the walls of the room they could not be brought to a focus in the great transit telescope, so the alternative is to fix them on each side of the room, interposing lenses between the wires and the telescope to atone for want of distance.

The principle being thus explained, we cannot do better than quote the technical description of this arrangement in the words of the Astronomer Royal: "For determining the error of collimation two horizontal telescopes of about five feet focal length, and

nearly four inches aperture, with their object glasses turned towards the centre of the instrument, are mounted on Y's, which are carried by massive brick piers, one on the north and one on the south side of the transit circle. The height of the axes of these telescopes is as nearly as possible the same as that of the axis of the transit circle. Each telescope is furnished with wires in its principal focus, to be used as collimating marks; and each telescope may be used as a collimator for the other, or for the transit circle telescope. The system of wires is the same in both, consisting of two parallel wires inclined to the vertical at an angle of about two and three-quarter degrees; two other parallel wires at right angles to the former, and therefore inclined to the horizontal line at the same angle (the intersection of this pair with the former producing a square), and a fifth wire parallel to the two last mentioned, and at a distance from the nearest of about ten times the side of the square. The middle portion of the fifth wire, which is included by the two nearly vertical wires, is in the same vertical with the middle of one of the nearly vertical sides of the square; and these middle points are the points adopted for observation. These wires are finer than the others." The frame carrying the north collimator wires are adjusted in altitude, and the frame of the south collimator in azimuth, by means of micrometer screws. To view one collimator by the transit circle telescope is easy, but to view one collimator by the other the transit circle has to be raised out of the way by mechanical appliances, and this is done every Monday.

An observation for the collimator of the transit telescope is made every night, the axes of the telescopes used as collimators having previously been brought into the same line with each other, or at all events strictly parallel. The central vertical wire of the telescope is then brought several times in succession upon the proper point of the nearly vertical wire of the north collimator, and the same operation is performed with the south collimator, the micrometer being read for each coincidence. The mean readings of both give the reading for the position of the line of collimation.

(To be continued.)

that particular wire it would also cross the meridian. Although the transit tube, with its iron axis and stone supports, only has the power of swinging over from the north to south, and cannot be turned toward the east or west, the mere mechanical arrangement is not sufficiently accurate for astronomical purposes.

For instance, should the tubes yield a little, the micrometer wires shift, or other faults in the telescope itself appear: a distant object in a line with the longitudinal axis of the telescope will not be represented by the object glass exactly upon the central micrometer wire, but to the right or left of it: so, should the astronomer register the time it is seen to cross that wire, he will do it at a period when the star is not on the true meridian. This source of inaccuracy in time and calculations is known as "the error of collimation." Now, if one fine perpendicular wire were fixed ten miles to the south of the transit tube, and another ten miles to the north, both being

TOOL HOLDER FOR THE SLIDE REST.

The illustration hereunto appended is, we believe, of Professor Willis's tool holder for the slide rest. In many cases no provision is made for placing the tool in various angular positions, and thus, if it is necessary to present the point of the tool to the work in an oblique direction, the tool itself must be bent, with all the consequent risks. By using Mr. Willis's contrivance, the tool may be fixed at any required angular position upon the table of the slide rest, and is besides capable of being entirely removed from the table, so as to leave it free for the others—as for drilling, cutting wheels, &c.

Fig. 1 is an elevation of the tool holder; Fig. 2 is the same shown in plan.

The tool is fixed by the action of a single nut A, tapped to the screw pillar B, C. This screw has a

(* Extracted from the Engineer.)

shoulder bearing on the surface of the table, and beneath this shoulder a short portion of screw C is tapped into a hole in the table; thus, the screw pillar can readily be removed by the key applied to the flat faces filed on the shoulder. It will further be observed that the pressure of the nut A is exerted on the triangular clamping piece D, E, F, Fig. 2, through the washer G, which, it will be seen, works freely in a corresponding cavity in the clamp, as shown in Fig. 1. Two steel studs, D, E, are driven into the lower side of the triangle, and rest on the upper surface of the stem of the tool. A screw, at F, is tapped stiffly into the triangle, and its lower end being rounded like the studs D and E, it follows that when the nut A is brought into action, its pressure upon the triangle is resolved upon the three bearing points below. To alter the angle of presentation, the nut is loosened, and tool and triangle are free, when the desired alteration is made, and a turn of the nut tightens all up again. But as it is necessary the tool should remain under the studs D and E, and so always at the same distance from the centre of the screw, the intermediate piece H, upon which the stud F presses, is contrived also to answer the purpose of guiding the stem of the tool readily to the distance. The dotted line *k*, *l* is the boundary of the lower

FIG. 1.

FIG. 2.

piece; at the opposite extremity a thick lump is formed in which a "pointer" notch is filed to show the centre of the screw pillar. This notch or groove, as explained, takes the end of the screw F. The form and thickness of the lump and the position of the groove are shown by the dotted lines. The triangle D, E, F, and the washer G, are drawn in section in fig. 1 to explain the adjustment of the latter. The upper surface of the washer is always horizontal, therefore the hole need be no larger than just sufficient to pass up and down the screw pillar. But it will be evident that as the tools to be accommodated vary in thickness, the case is different with the triangle; and, therefore, as indicated in the section, the hole through which the screw pillar passes should be large and slightly conical. The screw pillar should be fixed on the table of the slide rest at such a distance from the two edges that the three bearing points of the triangle may not hang over the edges in any position, but the tool clamped within the limits of the table—the dotted circle explains this. A circular hole in the centre of the piece H fits the shoulder of the screw pillar, the end of screw F is received in the groove of the intermediate piece—which latter is thereby kept in position below the triangle—and thus the triple combination may be swung round the central pillar without any derangement of position. The introduction of the screw F is to allow for the admission of tools of varying thickness; but as the spherical washer allows of pressure from the nut being transmitted equally to the bearing points, it follows that wedges of necessary dimensions may be readily applied to D, E, or F, in order to raise or depress the point of the tool. The tool may be placed either to the left or right of the screw pillar, and a spiral spring may be introduced below the triangle, to prevent it dropping

on the removal of the tool. Lastly, the triangle should be of such a size that the distance between its bearing studs D and E shall be the same as that given to the binding screws of an ordinary tool holder.

NEW VENT TAP.

Sir,—The enclosed "Tap" is simple and effectual as a preventive against sour beer. The idea may be useful to some of the readers of your ENGLISH

MECHANIC. The action of the thread in nut A removes or replaces pistons B and D over the air inlet, or draught outlet; F is an Indian rubber tube, connecting a passage from cylinder L with the barrel.

J. W. W.

SOLDERING.

THE appearance of this heading this week in our journal will indicate to "W. W." and "J. S.," two gentlemen who communicated with us some month or two since, how long it takes to satisfy in rotation the desires of our readers. That shown, we now proceed to remark on the modes of applying heat in soldering, which varies according to the size of the work, the manner in which it is to be soldered, and the fusibility of the solders. In hard-soldered works the fires used resemble those employed in forging iron and steel; in fact, the blacksmith's forge is used for brazings. Copper-smiths and others use a similar hearth, but it stands further away from the wall to allow of the centres of large objects being soldered; the bellows are generally worked by a chain from the rocking staff.

FIG. 1.

FIG. 2.

chafing-dish containing charcoal, the bellows being "actuated" by the attendant sprite. Care is taken to use charcoal or cinders in brazing, so that there is no danger of the presence of sulphur; in fact, the charcoal is often heated through, to drive off any sulphur. Another enemy to a good joint is lead, and a fire used for tinning should never, if possible, be used for brazing.

But the majority of cases in which soldering and brazing are applied in the manufacture are those which require the application of heat, together with

the power of observation, guidance, and definition of the pencil; and these conditions are only obtained by the blowpipe, where the gas is driven forcibly on the object by the use of the lungs as bellows, the object itself being often retained on charcoal, so as to retain as much of the heat as possible given from the flame of the gas. The ordinary blowpipe is a slightly conical brass tube, about a foot in length, from $\frac{1}{4}$ to $\frac{1}{2}$ inch diameter at the mouthpiece, and from 1-16th to 1-50th at the jet; the end is bent to keep the flame under observation. Fig. 1 shows the tool fitted with a ball for collecting the condensed vapour from the breath. This ball is best seen by the enlarged section at Fig. 2, where it is also shown that, the tube being discontinuous, no vapour can proceed in the direction of the arrow. The most intense heat of the blowpipe is that of the pointed flame; for, with a wax candle and a blowpipe having a small aperture placed slightly within the flame, small fragments of the metals are melted,

FIG. 4.

FIG. 3.

when they are placed upon charcoal and exposed to the blue, which is the hottest part of the flame—that is, fragments of those metals which do not require the oxyhydrogen blowpipe. When a very mild degree of heat is required, the object is removed further and further from the centre of the flame, sometimes, as in reducing the fluxes preparatory to soldering, to the stream of hot air beyond the tongue of the flame. Many artificers employ a large oil-lamp flame in soldering, the wick from a quarter to an inch in diameter, plentifully supplied with oil. In such case, the blowpipe is selected with a middling-sized orifice, blown vigorously, and held a little from the flame, so as to spread it in a broad stream over a large surface of the work, which is supported on charcoal. When a minute portion alone is to be heated, the pointed flame is used with a milder blast and a decreased distance. Fig. 3 is a Birmingham arrangement, used in cheap jewellery manufactories. A stream of air from a pair of bel-

The brazier's hearth is a flat plate, 4 x 3 feet, standing on four legs in the middle of the shop; but there are various contrivances for use out-of-doors, when workmen go out to jobs. The surface of the plate supports the work over the central aperture for the fuel, which is 5 or 6 inches deep, and about 2 feet long and 1 foot broad. The revolving fan is commonly used for the blast, and the tuyere irons are loosely fitted, to render removal easy. The hearth-hood is generally suspended from the ceiling, having a counterpoise weight in the most handy position, to admit of the hood being run up out of the way, or elevated to allow of the admission over the fire-aperture of large work, such as where a large T-shaped pipe has to be brazed. Very often, in using the common furnace, a muffle is inserted in the fuel so as to concentrate the heat on the object, but the amateur is generally content to use a

lows directs the gas flame down a shoot upon a flat disc of sheet iron fixed on a wooden handle, which disc is covered with a matting of fragments of wire beaten into a sheet, some of the bits turned down to hold on the disc. The work to be soldered is, as seen, placed on the wire, which becomes partially red hot, and retains the heat, though not so well as the charcoal, yet without the inconvenience of burning away and preserving a level surface, which is a great desideratum, very often, however, small cinders are placed on the disc, either upon, or instead of the wire. Occasionally, as in Fig. 4, the gas-

FIG. 4.

pipe is crowned with a head, with two blowpipes directed through. The makers of philosophical instruments very often use a table blowpipe, with a shallow lamp, as in Fig. 5. The wick must be plentifully supplied with tallow, and a furrow is made through it with a wire, to afford a free passage for the blast from the fixed nozzle. This lamp, by the way, has a loop placed lengthways upon the short diameter, for holding the cotton, which is sometimes an inch long, and half an inch wide. This lamp emits less smell, and is more cleanly than those supplied with oil, the fat being caught in the

FIG. 5.

outer vessel. Many blowpipes have been invented for the employment of oxygen and hydrogen, one or two of which we will describe. The general form of the workshop blowpipes is that of tube open at the one end, and supported on trunnions in a wooden pedestal, so that it may be pointed at any angle. Common gas is supplied through the one trunnion, and escapes through an annular opening; whilst oxygen gas, or, more often, common air, is admitted through the other trunnion, and is discharged through a central conical tube, in the centre of the hydrogen—the size and intensity of the flame being regulated by the relative quantities of gas and air, and by the amount of protrusion of the inner core by which the annular space for the hydrogen is contracted in any required degree. Mr. Gill's portable blowpipe furnace may here be noticed as deserving of a corner. It consists of a lump of pumice-stone three or four inches in diameter, scooped out like a crucible; into this cavity small pieces of charcoal are placed—sometimes a perforated cover is added. The interior may be intensely ignited, whilst the outside, through the slow conducting power of the pumice stone, is not repulsive to handling.

(To be continued.)

THE ENGLISH MECHANIC.—HIS RISE AND PROGRESS.*

(Continued from page 124.)

I have spoken at some length upon the early history of the Institution of Civil Engineers, because, in the blaze of its present prosperity, the struggles and the difficulties of its early life are apt to be overlooked, and we who have scarcely yet surmounted parallel trials, are sometimes regarded as unlikely long to survive them. We have not yet, it is true, been transformed from the chrysalis of the tavern to the butterfly of the hall, but we have aith in the coming change. At any rate, we may draw a moral from the past of the institution to

which reference has been made, and from its present flourishing condition take heart in our labours for the prosperity of our own.

Many other societies of equal eminence may trace their origin to the meeting of a few earnest men on the neutral ground of the tavern parlour, and it is scarcely fair towards this one to point the finger of scorn at it, because, as yet, its members assemble beneath the friendly roof of an inn.

I come now to a point in my rather crudely and imperfectly drawn sketch which I deem to be fraught with considerations of some moment, I allude to the future of the London Association of Foremen Engineers, and I must be allowed to say that if it is hoped that its onward progress may be rapid, our members generally must exert themselves much more than they have hitherto done. Few can estimate more exactly than the writer of this paper the anxious and responsible duties of a foreman engineer. I know that very frequently the cares of a harassing day are followed by the horrors of a sleepless night, during which the troubles of the morrow disturb the foreman's brain. I know that he has to rise early and leave his factory late, and that his intermediate occupations are often multifarious and difficult. All this I know, and much more of the foreman's ordinary life. Still it is my conviction that all may do something more towards forwarding the interests of their own association, and, in doing so, promote their own. It is astonishing what may be done by application, perseverance, and determination, and it would be possible to cite innumerable instances in our own profession in which the possession of those qualities have raised their owners to dignity, to honour, and to wealth. The biographies of scientific men teem with illustrations of the wondrous effects of the talismanic words just mentioned, and show those who have sought to rise

Out of the prisons of their mean estate;
And with such jewels as the exploring mind
Brings from the cage of knowledge to buy their ransom,
From those twin gaoles of the daring heart,
Low birth and Iron Fortune,

have succeeded in effecting their release, and in rising to liberty and greatness. It is not given to every man to be great, but there are few who may not be useful to their fellow-men if they but seek the means.

I must remember that I am not in a pulpit, however much these remarks may resemble part of a sermon, and I will return at once to plain speaking. It is my candid opinion, then, that each of the members of this Association should determine to read a paper, and do it. Each has had his workshop schooling, and there is no reason why (in workshop language if he will) he should not impart some of the knowledge he has gained to his neighbours. There is not one who now listens who has not gained some special information—who has not his mechanical pet, who cannot bring forth from the recesses of his mind some favourite theory, or who is not able to deliver himself of an inventive thought. We have had industrial exhibitions in which the products—valuable, curious, or grotesque—of the leisure hours of working men have figured *ad libitum*. My desire is that here we should have constant exemplifications of the cogitations of our members in their leisure hours, details of experiences in their busy ones, or speculations on future mechanical improvements. There is around me a mine of intellectual and mental wealth—it only needs working; the ore will then soon appear, and the conversion of it to useful purposes will speedily follow. The press will not only stamp that ore with approbation, but give it speedy currency, and pass it along the channels of general circulation. It has been often said that we have very few papers read, and that we therefore scarcely deserve the appellation of a scientific society. Let us endeavour to remove the stigma. It is in the power of each of us to assist in the task, and the will alone is wanting. Let the coming year display greater activity on our part than that which is passing away, and beyond doubt the influence and dignity of the institution will be much enhanced by the process.

From close and constant observations of the feelings, with some knowledge of the habits, and with great confidence in the practical knowledge of the members of this association, I feel assured that short suggestive papers, provocative of discussion, are the most desirable, and these, fortunately, are within the reach of all. You have little time to spare, no doubt, but such as you have could not certainly be more profitably employed. Bring out, then, your hobbies, and let us examine their claims to that distinction. I say this in all earnestness, because the future well-being of the society depends largely upon self help. It is impossible to command respect, if no efforts be made to attain it. If the Asso-

ciation is to stand independent and erect among its fellows, it must be by the exertion of its own innate strength, and not by the mere resting and being thankful for what has been done. Dante said, a long time since, that

He who beneath the covertlet reposes
On bed of down, can ne'er arrive at fame;
Without which, whosoever his life consumes,
Leaves of himself the visage on the earth,
As smoke in air, or bubble in the wave.

What Dante said of old is eminently true at the present time, when competition, not in trade only, but in knowledge and intellectual achievements, is the watchword; and when those who eat the bread of indolence, except the privileged classes, will speedily find that bread very bitter and unpalatable, if, indeed, they obtain bread at all.

It has already been observed that we desire the friendship of employers, and I can imagine a period yet to come, when those gentlemen will attend in this our lecture room and studio, not for the purpose of teaching us how to govern the institution, but for that of imparting to us information which their superior position, and more fortunate circumstances, have enabled them to obtain. I can imagine a time yet to come, when in this arena of friendly discussion, wherein it is desired that all opinions on legitimate subjects may be freely and unreservedly expressed, the employers of engineering labour will take part in our deliberations; and thus, while communicating knowledge, themselves derive, both directly and indirectly, advantage. When that happy period shall have arrived, it is my opinion that this Association will have attained to something like the amount of usefulness of which it is capable. We shall then have employers inducing not only their foremen, but their managers—the latter a class whom it would be well if we saw more of at our meetings—to assemble at our council table, and thus to add to the prosperity of the association. We wish class feeling—that enemy to comfort—that foe to all that ennoble human nature—and of which, from having been twenty-five years in a Government establishment, I have a painful knowledge—should disappear for ever, and that the mere accident of varying rank should not interfere with individual respect. It is time that the petty but stinging annoyances to which men are sometimes subjected, because they work with their own hands, or because they once did so, were forgotten. For ourselves, we wish to discard class feeling from our vocabulary, and I trust have learned that a man is to be respected, not for his rank or his position, but for his attainments and his character—not because he has been more fortunate, but because he is morally and intellectually better than his neighbours. In such spirit have the laws of this institution been founded, and in such spirit are, and ever will be, those rules, I trust, acted upon. From the fact that the association was founded by foremen, for foremen's material and moral good, it is impossible for those who have not attained a foreman's place to become participants in all its privileges; but our doors are open to engineering workmen, and our papers may be listened to and discussed by them. Their presence, indeed, is desired; they are admitted on the simple introduction of members, and gladly would we see more of them present on such occasions as this. When more accommodation shall be at their disposal, when the Foremen's Hall which has been spoken of shall be obtained, no doubt the committee will extend the number of their invitations, and that Hall will be filled by representatives of every branch and every grade of the engineering profession. At present there is necessarily a limit to those invitations, simply because there is a limit to the accommodation to be offered to those who might accept them.

(To be continued.)

THE PNEUMATIC DESPATCH TUBE.

The system of conveyance by atmospheric propulsion through a tube, which was lately exhibited in the grounds of the Crystal Palace, and had previously been tried on the short experimental line at Battersea, as well as in the neighbourhood of the Euston-square station, in Seymour-street and Ever-sholt-street, Camden-town, has now obtained an important practical extension by the opening of the line from Euston-square to Holborn—a distance of one mile and three quarters, whence it will be continued another mile eastward to the General Post Office, St. Martin's-le-Grand. The premises, No. 245, Holborn, which are the present terminus of the line, are well worthy of a visit of inspection.

Entering from the level of the street, the visitor passes along a corridor through a doorway, and emerges upon a gallery of considerable size, from

* A paper read by Mr. Joseph Newton before the London Association of Foremen Engineers, November 4th, 1865.

which he looks down on a brick floor, supporting lines of rails, much as he might do from a railway platform down to the line, but from a greater elevation. Underneath the corridor by which he has just entered he sees some mechanical appliances, suggestive partly of an engine-room and partly of a pointman's gallery outside a railway station; and below the level, again, on which the white-jacketed engineer in charge is standing, and supporting the platform on which both he and these mechanical appliances rest, are a couple of openings, looking like black, polished modern chimney-pieces with the grates withdrawn. These are the mouths of the pneumatic tubes, of which one communicates with the North-Western Railway; the other, idle at present, will soon be drawing in and delivering mail-bags from and to the postal head-quarters in London. The mouth of each tube is shut, when the tube is exhausted of air, by iron folding-doors, which meet, not evenly, but at an angle projecting outwards so as to resist the atmospheric pressure from without. These doors are made to fly open on the approach of the train, the bolt which closes them being withdrawn by the action of a spring lever, which underlies the rails, and gives way beneath the weight of the train. The carriages are shaped like a capital D turned over on its straight side, and mounted upon wheels. Each end of the carriage has a raised head, or flange, shaped so as to correspond with the interior of the tube, the dimensions of which are 4 feet in height by 4 feet 6 inches in width. Their ordinary freight is expected to be in the first instance letter-bags, then probably railway parcels, certain descriptions of market produce, and ultimately it may be general merchandise.

On the opening day the Duke of Buckingham, chairman of the Pneumatic Despatch Company, had invited a number of scientific gentlemen to inspect the apparatus. After the train had made some successful passages to and fro, several of the party expressed a strong desire to pass through the tube themselves. They were warned that the line was "not constructed with a view to passenger traffic," and that they might find the way "a little rough." The spirit of adventure, however, prompted them to take this strange journey, and each of the wagons had soon as many occupants as it could comfortably accommodate in the recumbent posture enforced by circumstances. Tarpaulin coverings were obtained for one or two of the carriages, but the greater number of the excursionists had to fit themselves in as best they could among the bags of shingle, which made up the temporary loading, taking care to keep their heads well below the edge of the carriages.

"The sensation at starting, and still more so upon arriving (say some of the passengers) was not agreeable. For about a quarter of a minute in each case there was a pressure upon the ears suggestive of diving-bell experience; a suction like that with which one is drawn under a wave, and a cold draught of wind upon the eyes, having almost the effect of falling water; but, once fairly within the tube, these sensations were got rid of, or left behind, and the motion had little more positive comfort about it than would be attendant on riding on a 'lorry' over the worst ballasted line in England." The air within the tube was by no means foul or disagreeable; here and there a strong flavour of rust was encountered, but this was explained by the fact that, as the tube had to be laid in lengths, through various soils, and encountered in the process a large share of unfavourable weather, the corrosion on the surface of the iron could not be expected wholly to disappear until cleared away by the friction of constantly passing and repassing trains. On the arrival of the excursionists at the upper or Euston-square extremity of the line, they quitted their places for a few moments to inspect the smaller tube, which communicates with the Eversholt-street district post-office, and then returned by the way they had come to Holborn.

No doubt remained on the mind of any person who witnessed the opening trip as to the facilities which the system, if a sufficient number of stations can be incorporated with it, is calculated to afford, not only to the postal service, but to the requirements of the general public. The scheme of the company, who, it seems, possess under their Act powers to lay down pneumatic tubes at any points within the jurisdiction of the Metropolitan Board of Works, is to construct similar lines to that now opened between the ten district post offices and the General Post Office, and between the different railway termini and goods depot in London, connecting with these lines the six principal London markets and other important points. For these purposes it is calculated that some thirty-five miles of tubing and a capital of £1,250,000 will be required, the cost per mile, roughly estimated,

being from £30,000 to £35,000. The expenditure of the company hitherto has been probably £150,000, which would be largely in excess of this supposed average; but the sum mentioned includes the cost of preliminary experiments, and also for seeking for two Acts of Parliament. The company expect that great profits will eventually accrue to them from the carriage of goods.

REVIEW.

(Continued from page 129.)

A Treatise on Gas Works, and the Practice of Manufacturing and Distributing Coal Gas. By SAMUEL HUGHES, C.E.; Revised by W. RICHARDS, C.E. London: Virtue, 1, Amen Corner, Paternoster-row.

The recent unfortunate explosion and consequent wreck at Nine Elms created a great fear in the metropolis, which was not allayed by certain daily journals stating that the city was at the mercy any day of the great gas-works. They are only at the mercy of the companies, so far as regards the quality and price of the article; and very likely the action of the Corporation in the next Session of Parliament may "break the charm and loose the spell." The following extracts from the chapter on explosions and accidents cannot prove other than interesting:—

"Explosion is an instantaneous ignition of a mass, and that mass may be solid or gaseous; thus, a mixture of charcoal, sulphur, and nitre in certain proportions, and prepared in a particular manner, forms gunpowder, which ignites instantaneously, and the increased volume, occasioned by the solid assuming the gaseous state, is the cause of the force or power attending the combustion. There are numerous other solid compounds even more explosive than gunpowder, but the simple mention of this will be sufficient as example.

"Certain gases, like the solids, when intermixed in due proportion, are likewise capable of instantaneous combustion; for instance, hydrogen when intermixed with oxygen, as before stated, in the proportion, by volume, of two of the former and one of the latter, ignites, producing explosion; and coal gas when combined with air in certain proportions is also explosive, this being due to the hydrogen and carbon composing it entering into combination with the oxygen of the atmosphere, producing water and carbonic acid gas; and the nearer they approach to the proper proportions for the perfect formation of these compounds, the greater is the force of explosion. A mixture of seven parts of air and one of gas is considered to be the most explosive compound, but this must depend on the quality of the gas. Mixtures of less than three of air to one of gas, or more than eleven of air and one of gas, do not explode.

"At one period or other, in some of the largest cities of the United Kingdom, as well as those of the Continent, gas-works have been the scenes of explosions. This has often arisen from a new gasholder, when nearly terminated and ready for use, having, from a very simple oversight, been communicated with the manufacturing apparatus; and it has afterwards happened that through a leaky valve allowing the gas to pass, or perhaps by some careless person thoughtlessly opening the valve, the gas has entered, intermixed with the air in the holder, and the accidental production of a light has caused the disaster. Therefore, when new holders are constructed they should either not be communicated with the manufacturing apparatus until quite terminated, or the pipes should be "logged," or sealed with water, so that no gas can possibly enter until quite ready for use.

"But explosions of this nature have occurred when the holder was being first filled with gas; one of the most remarkable took place a few years ago, by which the engineer was killed. This arose from a defect in the construction, and want of ordinary caution on the part of the unfortunate sufferer. The facts are simple, for the holder on being charged with gas at the commencement of the operations contained a considerable quantity of air, the two forming an explosive compound, and by a singular fatality it happened that the holder was so far bound, or set, as not to give any pressure. The engineer being desirous of judging the quality of gas, very imprudently tried it at an open orifice of about $\frac{1}{2}$ inch diameter; the consequence was, the flaming entering, the explosive compound in the holder ignited, and produced the disaster. Had the gas been tried by an argand or fish-tail burner the accident would not have occurred, the holes in these being too small to permit the flame to enter.

"Explosions have taken place in station meters when newly erected, just previously to their use, this arising from causes already mentioned—by leaky valve, or by unnecessary meddling on the part of the

workpeople. On one occasion which came under the writer's notice, a calamity of this kind occurred from the mixture taking fire through the men making the joint with overheated lead. And this suggests the varied opinions as to the possibility of a spark igniting gas. The general opinion is that gas cannot be ignited by that means; and, indeed, it is difficult to be done, but by chance a spark may be produced of sufficient heat to inflame gas.

"Accidents have frequently occurred when lying mains; often occasioned by bladder-valve, which has permitted a small portion of gas to pass into the main beyond it, where the explosive compound was formed, and by the merest hazard a neighbouring light has produced the calamity; therefore, in lying mains, when practicable it is always better to have a sheet-iron temporary valve, which is done by having the spigots of two pipes together where the stoppage is desired, and a thin sheet of iron between them, which may be clayed or cemented round to prevent the leakage of gas. The plate can be removed when requisite, and a temporary or permanent joint made with a running socket.

"An erroneous impression exists that if a gasholder were to be rent by accident, and the gas ignited, whenever the holder touched the ground, and there being no pressure, that the contents would explode. This is incorrect, for, no matter the size of the opening, when the pressure ceased the gas would be extinguished; but from this moment danger would commence, for a portion of the gas remaining in the crown would gradually issue, and air take its place, so by degrees an explosive compound would be formed.

"An explosive compound of gas when under pressure only ignites at the exterior of the pipe; but if the pressure be taken off, the flame enters, and it explodes.

"An explosive mixture always possesses a very powerful odour of gas; this is sufficient to indicate to any one that a light should not be approached; and under these circumstances, when in dwellings, ordinary precautions only are requisite: above all to have no lights near, and to open the doors and windows, the upper part of the latter especially, as gas by its lightness ascends, and will readily escape thence. The main tap should be turned off, and a careful inspection made, when perhaps a burner will be found turned on, or an hydraulic joint without water, or some other defect which can easily be remedied. No one should ever apply a light where there is an odour of gas in the upper part of an apartment; many little mishaps have occurred through neglecting this precaution. Should there be any escape which can only be detected by flame, the gas ought to be turned off for two or three hours, and the other precautions being adopted, the light may be applied the moment the main tap is turned on; but it is always better and safer to detect escapes in dwellings without the employment of a flame, it requiring only a little more patience.

"Meters are sometimes mysteriously destroyed by explosion, even when fixed in their places. The syphon plug when not sealed by water, and the tap of a burner being left open, are sufficient to permit air to enter and form the explosive compound, and a light being applied to an orifice without a burner, the flame enters, but does no injury beyond rendering the meter useless.

"Of the few explosions that have occurred in gas-works, the majority have arisen from having the pipes in vaults and tunnels, or perhaps from open spaces existing under some of the apparatus, generally with the view of seeing to the perfect condition of the pipes, &c. From this originated the first two accidents of the kind, which befell Mr. Clegg, forming a very powerful argument against the use of subways, proposed some time ago, for containing gas mains; and if these were unfortunately to be carried into operation, all the extravagant fears of danger which existed at the introduction of gas would certainly be realised.

"On the occasion of a fire occurring near gas-works, the public journals generally fall into error by assuming the contents of the gasholders to be explosive, and conjecture the amount of damage that would arise from this event occurring, the excitement being much increased by this mis-statement. Gasholders when in use, that is, contain ordinary gas, cannot by any means explode, even although the plates forming them were to be made red-hot by the flames: all that could occur is that the gas, expanded by the heat, would issue in detached flames, but no explosion could take place. Another common error, when an edifice, as a theatre, takes fire, is to turn off the gas to prevent explosion, and this is done sometimes at the risk of putting the audience in darkness to find their way out in the best manner they can. Nothing is more absurd; for supposing, at the worst, the fire

to melt the pipes in the building, and the gas to issue, the same flame which melted the pipe would ignite the gas, so that explosion is not possible under these conditions. A good system is to have a valve or valves on the exterior of all public buildings of resort, which, in the event of a fire unfortunately occurring, can be shut off after all the people have left the building, so preventing the destructive effects of the flame should the gas ignite, and the loss of gas."

But here we must call a halt. There is something in this wonderfully cheap volume for everybody, and everything for the person interested in gas making and selling. At no more opportune moment than the present could this edition have made its appearance; it reflects equal credit on its author, editor, publisher, and printer; and we trust its sale will be so extensive as that in a short time no man of any intelligence can be found ignorant on the subject of gas.

ANSWERS AND NOTICES TO CORRESPONDENTS AND READERS.

ALL letters intended for the Editor should be addressed to 75, Fleet-street.

Letters applying for information to be furnished by post cannot be attended to.

Correspondents are requested to keep copies of their drawings and manuscripts, as the Editor cannot undertake to return such as may be rejected.

T. A. COTCHETT.—Thanks for your kindness.

J. MAID.—You had better not try the experiment.

DAVID KNIGHT.—Will appear, if possible, next week; but we are terribly crowded just now.

J. B. P.—Write to Spon, Bicklersbury.

R. D.—Watch for answers to W. Sale.

BIRMINGHAM.—Mr. Tonkes may comply with your wishes. Send your address to us in an envelope, and Mr. Tonkes will receive it.

B. HOLBROOK.—Of Edgeley, Engineer, Lamb's Conduit-street, Bloomsbury.

J. S.—Evidently a printer's blunder. We regret that it occurred.

G. WATSON.—In a future number.

E. VINCE.—Will receive attention.

H. W. M.—Write to Virtue, Amen Corner, Paternoster-row.

ROBERT THOMPSON (Oldham).—The lathe was patented in 1863, by E. H. Wael, of Warren, Ohio, United States. You can obtain any information you require through Munn and Co., Patent Agents, New York, U. S.

COATING BRASS AND COPPER WITH TIN.—The address of our correspondent who wrote on this subject in May last is required by A. W.

A. YOUNG FLANNERY.—Exp'ain yourself more clearly.

W. H. H.—We have complied with your request this time, but we cannot spare space for tradesmen's addresses.

C. SIMPKINS.—Apply to Mr. Rimmel, Perfumer, West Strand, London.

MR. LONSDALL.—We are sorry to say that we cannot obtain the address.

E. J. WITCHELL.—Unable to engrave this week—perhaps next.

WILLIAM COOPER.—Received, but far too lengthy for insertion.

F. MASON.—See reply in number for December 5. If still dissatisfied, write again.

A WORKING APPRENTICE.—You had better serve your full time, and receive your indentures endorsed favourable to your character and craftsmanlike perseverance.

WOODEN HEAD.—We advise you to search through the back numbers. Many letters and engravings have appeared.

W. SALE.—The experiment has yet to be made in a small way.

W. E. S.—We are going to look at a new boiler, which we are informed is somewhat on the same plan. We will then give opinion.

F. H. COLLINS.—Published by Munn and Co., Patent Agents, New York, U. S.; London agents, Sampson, Low, and Co., Ludgate-hill. A quarter's payment in advance. Receive the paper four weeks after payment.

W. C. C.—You can purchase a flexible one of Bailey and Co., 418, Oxford-street. The price will depend upon workmanship and trouble in fitting.

* * We have to ask our correspondents to so sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them by the thousand; the same with "Well-Wisher," &c.

AVENTURINE.

Venice has long been celebrated for its beautiful imitation of aventurine; but the material it furnishes to the lapidary has been far exceeded in every respect by a compound recently discovered by Pelouze. The real aventurine is a variety of quartz, containing throughout its mass minute spangles of mica. The imitation obtained from the glass-works of Venice is a glass, coloured by oxide of iron, and having diffused through it crystals of metallic copper; its composition remained a secret, until discovered by MM. Fremy and Clemandon. They found that

it may be formed by fusing together, and keeping at a high temperature for twelve hours, a mixture consisting of 800 parts pounded glass, 40 parts protoxide of copper, and 80 parts oxide of iron, and then allowing the mass to cool gradually.

During his experiments, M. Pelouze observed that, not only sesquioxide of chromium, but also bichromate of potash, communicates a green colour to vitreous compounds: the bichromate being decomposed by heat into oxide of chromium and neutral chromate of potash: which latter is decomposed by the silica, oxygen silicate of potash and oxide of chromium being the result. If the oxide of chromium thus produced is small in quantity, the glass is perfectly transparent, and of a light green tint; if, to a certain extent, large in quantity, very brilliant spangles of sesquioxide of chromium are diffused through the glass. Using always 250 parts fine sand, 100 parts carbonate of soda, and 50 parts carbonate of lime, he made experiments with various amounts of the bichromate of potash, but found that the best proportion for it was 40 parts. This compound is somewhat difficult of fusion, but is far more easily prepared than that of Venice. It is filled with extremely brilliant crystals, and in strong light yield only to the diamond in splendour; it is worked with ease, though much harder than the aventurine of Venice. It has been termed *chrome aventurine*. The spangles have a decided tendency to the form of an irregular hexagon, belonging to the same system as the sesquioxide of chromium; and they resemble certain varieties of oolite iron, with which, indeed, sesquioxide of chromium is isomorphous, and especially with that species termed *specular*. The colour of the Venetian aventurine is brown; that of the new kind, a beautiful yellowish green, which is much finer. It takes a high polish, and is not liable to be scratched, and thus lose its lustre, as it is so hard that it will cut glass.

GENERAL NOTES.

ELECTRICITY AS A MEANS OF TAKING CORRECT SOUNDINGS IN DEEP WATERS.—In taking deep-sea soundings, the great difficulty is to determine the exact moment at which the lead touches the bottom. Several very ingenious contrivances for overcoming this difficulty have been devised of late years, but none of them have proved so successful as one which has just been suggested by M. Hedouin of Lyons, seems to promise to be. M. Hedouin proposes that the sounding line should be a kind of light telegraph cable, enclosing two carefully insulated wires, both connected, at one end, with the lead, and at the other with the two poles respectively of a voltaic battery, and that the lead should be so constructed that on touching the bottom it should make metallic contact between the extremities of these two wires, and thereby cause the instant passage of an electric current. It is obvious that this current could be made either simply to give warning, by ringing a bell or otherwise, of the lead having touched the bottom, or to put in action an automatic brake, and so prevent any more line passing into the water.—*Mechanics' Magazine*.

THE BESSEMER PROCESS BY GAS.—Last week an influential company assembled at the new works of the Mersey Steel and Iron Company, at Liverpool, to witness some interesting experiment with this new process. There are two furnaces capable of receiving ten tons of metal each. In one of these, which is heated by gas, the iron is first melted, and in the adjoining one a composition of manganese is also melted. The two molten liquids are then run into a huge crucible, through which a blast is forced by two engines, of 100 horse-power each, and the combustion then clears the mixed metal from all impurities, and transforms it into cast-steel, in which condition it is finally run into ingot moulds. The experiments were entirely successful, and were witnessed by several influential gentlemen.

THE COPPER SMOKE QUESTION.—It is well known that the utilisation of copper smoke has attracted great attention of late years, and only a few weeks ago particulars of a German invention in course of adoption at Messrs. Vivian and Sons works, Swansea, were given in the *Times*. Mr. H. H. Vivian, M.P., announced at a public meeting since held that he had every confidence in the success of the invention, and that in a short time the copper smoke from his works, which had been so injurious to the land around, would not only be rendered innocuous, but of great commercial value, by condensing it through various processes to sulphuric acid. Within the last few weeks Mr. Thomas Bell has brought forward another invention, which, since his letters in the *Times*, has attracted considerable attention. That gentleman has visited Swansea, the seat of the cop-

per smelting trade, and he was introduced to the copper smelters at the last ticketing meeting, when he laid his plans before the parties then present, and he was invited to visit several of the principal local establishments in order to test the invention. From these facts it is inferred that before long the injury caused by the copper smoke will not only be neutralized, but the smelters will reap a handsome return from its utilization.

PATENT LIST.

(From the Commissioners of Patents' Journal.)

LIST OF SPECIFICATIONS, &c. PUBLISHED DURING THE WEEK ENDING 2ND DECEMBER, 1865.

157. Watches, C. D. Abel—64.
158. Preparing cotton and other fibrous substances, T. Mayor—44.
159. Coupling steam engines, &c., F. Freger—149.
160. Treating ores, M. B. Mason—84.
161. Actuating ores, E. D. Farcol—14.
162. Threshing and doubling frames, E. Williams—104.
163. Sewing machine shuttles, G. F. Bradbury—84.
164. Buckled plates for railways, &c., A. Mallet—14.
165. Shaping and forging metal, &c., Shipston and K. Mitchell—104.
166. Steam engines, W. C. Hicks—14.
167. Locomotive and other steam engines, T. C. Durham—84.
168. Dyeing leather, T. Labrousse and J. Kelly—44.
169. Boots, shoes, saddlery, &c., W. Clark—44.
170. Painting venetian blinds, &c., D. Mauro and T. Wright—104.
171. Projectiles, G. A. Clark—44.
172. Machinery for treating leather, J. Turney the younger and G. Wood—24.
173. Puddling and other furnaces, J. Hewes—14.
174. Binding, carrying earth, stones, corn, &c., L. Balma—104.
175. Shirt studs, C. Seale—44.
176. Preparing and applying vulcanizing compounds, B. F. Stevens—44.
177. Collecting and delivering mails at railway stations, W. Clark—14.
178. Facing woollen cloth, &c., J. Seall and W. Ranton—84.
179. Signalling on railway trains, W. Mather—44.
180. Hydraulic lifts, W. Clay—14.
181. Pile-driving machine, W. E. Newton—44.
182. Carriage stops, H. A. Dobson—44.
183. Steam engines, T. Lester—104.
184. Railways, J. G. Wilson—44.
185. Clamps and snaps, A. L. L. Gordon—84.
186. Pumps, J. H. Wilson—104.
187. Collecting and delivering mails at railway stations, C. D. Abel—44.
188. Fire-arms and ammunition, J. Snider—14.
189. Machinery for shaping the elastic dent of expanding and contracting combs, M. Robinson—14.
190. Boots and shoes, J. Eadie—44.
191. Glazing and cleaning cotton, C. Brakell, W. Hoegl and W. Gunther—104.
192. Treating cast-iron articles, P. M. Parsons—44.
193. Suspending curtains, J. Bulcock—44.

* * Specifications will be forwarded from the Commissioners of Patents' Office, Southampton-buildings, Chancery-lane, by post on receipt of the amount of price and postage. Sum exceeding 5s must be remitted by Post-office Order, made payable at the Post-office, 5, High Holborn, or Mr. Bonnet Woodcroft, her Majesty's Patent Office. We cannot undertake to forward Specifications, or Books advertised from the office of THE ENGLISH MECHANIC.

MONEY ADVANCED in sums of any amount for long or short periods, on one or more securities required, except the security of a day's deposit on mortgage is given. Life assurance is optional.—NATIONAL GUARDIAN ASSURANCE COMPANY (Limited), 481, Oxford-street, Bloomsbury, W.C.
THOS. BOURNE, Res. Sec.

UPFIELD GREEN,

JOINERS' HALL BUILDINGS, 79, UPPER THAMES STREET, E.C.,

LITHOGRAPHER, PRINTER, ARTIST, AND DESIGNER,

PLANS, DESIGNS, SPECIFICATIONS, AND EVERY DESCRIPTION OF ENGINEERING DRAWINGS EXECUTED WITH RAPIDITY AND ECONOMY.

Estimates Forwarded for All Kinds of Turf Clocks.

Estimates Forwarded for All Kinds of Turf Clocks.

GOLD FROM 5 GUINEAS.

SILVER FROM 3 GUINEAS.

TUCK'S PATENT STEAM PACKING.
FOR STEAM-ENGINES,
PUMPS, &c.

ADVANTAGES.—A more perfect vacuum is obtained. Friction reduced, great saving in oil and tallow, and the Packing is gradually and completely worn away without becoming hard. Thus obviating the necessity of drawing the Old Packing. J. H. TUCK & CO., 35, CANNON STREET, E.C. WORKS, LAMBETH.

J. H. TUCK & Co., beg to call attention to the annexed "TRADE MARK," which in future will appear upon each length of TUCK'S PATENT PACKING, as also upon their other Rubber Manufactures. Valves guaranteed quality. Sheet India-rubber. Hoses, Tubing, Banding, Buffers, &c.

J. H. TUCK and CO., 35, CANNON STREET, E.C. WORKS, LAMBETH.

"EXCELSIOR," "EXCELSIOR"

Family Sewing & Embroidering Machine

WITH ALL THE LATEST IMPROVEMENTS.

IS easy to operate, simple to learn, quiet in action, and not liable to derangement. It will TUCK, HEM, FELL, GATHER, CORD, QUILT, BRAIL, and sew from two ordinary reels, requires no re-winding, and the seam, if cut at every inch, will not rip. Price from £6 6s.

WRIGHT AND MANN, 143, HOLBORN BARS, LONDON.
MANUFACTORY—GIPPING WORKS, IPSWICH.
PRICE LISTS FREE.

Crickmer's Patent Plastic Metallic Packing.

FURTHER REDUCTION IN PRICE ON AND AFTER OCTOBER FIRST.

PATENT WIRE GAUZE JOINT PACKING...	1s. 6d. per lb.	INDIA-RUBBER CORE PACKING...	1s. 6d. per lb.
CRICKMER'S PATENT PACKING...	2s. 3d.	Do. Do. (COTTON)...	2s. 6d.

This Packing takes less Tallow to lubricate it than any other, and being a Pliable Metallic Surface, requiring but little Pressure to keep it Steam tight, there is a great saving in friction.

PATENT TALLOW PUMPS AND LUBRICATORS.

WELL STRETCHED LEATHER MILL BANDS, HOSE PIPES, FIRE SUCKERS, VALVES, WASHERS, &c., &c.

CAUTION.—Engineers, Millwrights, and others are Cautioned against Purchasing a Spurious Metallic Packing, purporting to be Crickmer's. THE GENUINE CAN ONLY BE OBTAINED FROM

ALEX. ROSS AND CO.,
GRANGE ROAD, BERMONDSEY, the only Authorized Agents. Price Lists on Application.

No Fitter or Turner should be without a Straight-edge.
The most reliable tool of this kind, graduated to the Standard Measure of the Realm, and manufactured with MARVELLOUS ACCURACY, may be obtained of

RICHARD LLOYD,
MILL AND MACHINE IRONMONGER
135, STEELHOUSE LANE, BIRMINGHAM.

Clubs of Workmen supplied at reduced prices. No equal tool is sold under FOUR TIMES THE PRICE.

CHANGE WHEELS FOR SCREW-CUTTING LATHES.

JUST PUBLISHED,

HENRY LAXTON, C.E., and Architect, 34, Arundel-street, Strand.

HOLLOWAY'S OINTMENT AND PILLS.
Cold and Damp are the frequent causes of ailments which
prove troublesome, though rarely dangerous, unless culpably neglected.
A cold in the head, throat, or chest, may be safely stopped and ex-
pediently cured, by rubbing Holloway's Ointment twice a day upon
the neck and chest, and by aiding its curative powers with ap-
propriate doses of his purifying and regulating pills, the conjoint
reciprocal agency of these medicaments exercises the highest salutary
effect over the mucous, vascular, and secretory systems, which cools
always inconvenience and disarrange. The phlegm, cough, and short-
ness of breath gradually disappear under this rational treatment, and
the strength and vigour of the constitution are increased rather than
diminished during the course of cure.

PATENT HOLLOW STEAM PACKING.

THE great and peculiar advantages of this Packing consist in its remaining perfectly elastic, and is so constructed and applied that the pressure of the steam itself makes the joint by entering the packing from the cylinder; thus the many objections to packing previously existing are effectually removed.

Vulcanised India-rubber Sheet Washers, Valves, Springs, Hose, Glazed and Solid Tubing for Gas, Speaking Tubes, Diving Dresses, Gas Bags, Air-proof Goods, or any description of India-rubber articles made to order.

Price list or circular, with full description of packing, to be had of the only Manufacturers and Patentees of Hollow Steam Packing.

FOSTER and WILLIAMS, India-rubber Works, Cowper-street, City-road.

31, CHURCHSIDE, and LEICESTER.

The above Lubricators grease every particle of steam previous to its passing through the valves into the cylinders.

INVENTIONS PROTECTED BY PATENT or REGISTRATION, at fixed and most moderate charges. The Inventors' Manual free by post, or gratis on application.—Apply to Mr. BREWER (late Barlow and Co.), 89, Chancery-lane, London, W.C. Established 41 years.

INVENTORS ASSISTED

IN Scouring, Carrying Out, and Disposing of their Inventions.—Apply to Mr. BROWNE and CO., British and Foreign Patent Office, 49, King William-street, London-bridge.

A Pamphlet gratis, on Cost of Patents, may be had on application.

INVENTIONS secured by Patent or Registration, on moderate terms, by application to Mr. WILLIAM BROOKES (of upwards of 25 years' experience in such matters). British and Foreign Patent Agency, 62, Chancery-lane, London, W.C.

TO INVENTORS.—GENERAL PATENT OFFICES.—L. de FONTAINEMOREAU, 4, South-street, Finsbury, London; 14, Rue de la Fidelité, Paris; 33, Rue des Minimes, Brussels. Provisional protection, 27; to complete patent, £30; French patent, £6 10s.; Belgium, £2 10s. Circular gratis on application.

PATENTS FOR INVENTIONS.—Full Instructions may be obtained by applying to Mr. W. T. RAWLE, Office of British and Foreign Patents, 8, Small street, Bristol.

NOTICE TO INVENTORS.—Office for Patents, 4, Trafalgar-square, Charing-cross. Printed Instructions (gratis) as to the Cost of PATENTS, for Great Britain or foreign countries. Advice and assistance in disposing of or working inventions. Branch offices and agencies in every Continental State and in America. Established 30 years. Full information as to expired or existing Patents at home or abroad. Apply personally or by letter to Messrs. PRINCE and Co., Patent Office, 4, TRAFALGAR-SQUARE, CHARING-CROSS, W.C.

WHEEL, RACK, and SCREW CUTTING. SPUR, BEVEL, RATCHET, WORM and INTERNAL WHEELS cut to any size or number of teeth; also racks of any length or pitch. Dividing plates drilled or lined. Screws cut to any size or pitch. J. Wilkinson, Engineer, St. George's Works, 83, St. George's-road, S. London.

A MARVEL OF CHEAPNESS.—THE newly Invented POCKET TIMEPIECE, with handsome gilt case, and an elegant enamelled DIAL, interspersed with gold, price by post 14 stamps.—JOB MALPASS, Kidderminster.

THE LONDON DRAWING ASSOCIATION for supplying Engineering, Mechanical, Architectural, and General Drawing, Designs, Maps, Plans, Tracings, Wood Engraving, Electrotyping, 7, Duke-street, Adelphi, London. Enclose stamp for prospectus.

SECOND-HAND CASES OF MATHEMATICAL INSTRUMENTS. Theodolites, Levels, Pentagraphs, Quadrants, Sextants, Universal Dial, Protractors, Circumferencers, Primatic and Beam Compasses, Ivory and Boxwood Scales, Land Chains, &c., by Troughton and Simms, Elliott, Dolland, and others, at WM. LAWLEY'S, 78, Farringdon-street, City. Photographic Cameras, Lenses, Magic Lanterns, Slides, Dissolving View Apparatus, Microscopes, Telescopes, Opera, Race, and Tourist's Glasses, by Veiglander, Ross, Dallmeyer, and others. Instruments bought or exchanged. Catalogues forwarded on receipt of three stamps for each.

SCREW CUTTER'S GUIDE,

Price 1s. 6d., or stamps.

Containing 115 Pages and nearly 2,000 Trains of Wheels, all different threads and pitches.

Tables for Tap making for Engineers, $\frac{1}{4}$ to 6 inches, Gas Taps $\frac{1}{16}$ to 2 inches, Mr. Whitworth's thread and make.

A lithograph showing a new radius gear invented by the author of this work.

May be had at James Martin, 19, Wilson-street, New Cross-road, Deptford, Kent.

Self-acting, Turning, and Screw-Cutting Lathes,

OF THE FOLLOWING SIZES,

For Sale, and Ready for Delivery:—

Height of Centres.	Length of Bed.
6 $\frac{1}{2}$ Inches.	6 Feet.
7 "	8 "
7 $\frac{1}{2}$ "	14 "
8 "	8 "
8 "	12 "
8 "	13 "
10 "	16 "
11 "	16 "

Also a large Assortment of Single and Double Geared Drilling and Boring Machines; Planing, Shaping, Slotting, Bolt Screwing, Punching, and Shearing Machines; Hydraulic Jacks, Screw Jacks, and other Tools.

Apply to **W. BLACKETT, Hope Iron Works, 106, Southwark Bridge Road, London.**

E. BOURDON'S PATENT GAUGES.—GIFFARD'S INJECTORS.

Drawings and Prices on Application to

W. T. HENDRY, & Co., 73, QUEEN STREET, LONDON, E.C.

BRITISH AND FOREIGN PATENTS AND THE REGISTRATION OF DESIGNS.

Mr. H. H. MURDOCH having succeeded to the Business of his late Father, which has been established upwards of Thirty Years, offers his professional services to inventors. A circular, containing full information respecting the various modes of securing protection for inventions at home and abroad, may be had, Gratis, by applying (personally or by letter), at his OFFICE FOR PATENTS, 7, STAPLE INN, LONDON.

PATENTS.

MR. VAUGHAN, Member of the Society of Arts, British, Foreign, and Colonial Patent Agent, 64, Chancery-lane, W.C. Transacts every description of business connected with Letters Patent for Inventions. Provisional protection, 6 to 8 guineas. A "Guide to Inventors" free by post.

SAMUEL BROTHERS,

[PRICE ONE PENNY.]

GENERATION OF STEAM POWER BY GAS HEAT. (JACKSON'S PATENT.)

WE present our readers this week with diagrams of a boiler heated by gas. The application of gas for such purposes is the patent of Mr. Arthur Jackson, of 26, Philipot-lane, City. The advantages of this source of heat are necessarily very great, as all dirt and smoke are avoided, the expenses of stoker and carting of coal and refuse saved, and the furnace is kindled or extinguished instantaneously.

The boiler represented in our drawings is of four horse power, and is fixed without any brickwork or chimney. When the engine is in full work the maximum expenditure of gas is guaranteed for the indicated horse power, and when it is not the consumption can be instantly reduced.

This plan offers great facilities for introducing steam power into warehouses and small manufactories, from the little space required, and from the absence of all danger of fire. It has been approved of by the Warehouse and Wharf Committee of the London Fire Offices, and by their surveyor, Charles Freeman, Esq., and with ordinary precaution can be generally adopted without incurring any additional premium.

A, gas furnace; B, gas chamber; C, gas burners with clay discs on surface; D, cock; E, valve for

admission of air; F, pedestal containing furnace and supporting boiler; G, tube for circulation of water; H, water line; J, furnace door, which being of glass or mica, the furnace can be inspected without opening, and the gas regulated either by the separate cocks D, D, which are all outside, or by the main cock, thereby avoiding the admission of cold air.

Mr Thomas Middleton, of Loman-street Works, Southwark, is the appointed manufacturer.

TREATMENT OF IRON FOR RAILS.*

The chemical composition of iron undoubtedly exercises a considerable influence upon the character of the ultimate produce, and too much consideration cannot be given to its constituents. But there is yet another point to which an equal amount of attention is necessary, and this is the mechanical treatment of the metal. This is an important point, and one quite irrespective of chemical components. The general practice in Wales is to use the ordinary squeezer, although in some works a patent squeezer, consisting of three grooved eccentric rollers, is used, and this is certainly a preferable machine to the

other. The compression of iron is otherwise mechanically effected by the old tilt hammer and the steam hammer. At one time the tilt hammer was the only means of compression used, but since the furnaces have been driven, and forge and finery cinders and impure ores have been used, an inferior iron has been made, which will not stand the old tilt, and so the squeezer was introduced. By this instrument almost anything can be shingled into a bloom and passed through the rolls, whereas, with the old tilt, the iron, from first to last, has to bear the full weight of the blow. With the steam hammer, however, the case is different, as the blow can be regulated to any nicety. Specifications for rails frequently contain the stipulation that the iron shall be hammered, and not squeezed, and the plan has been adopted of doubling the puddle balls by slightly hammering them, placing them one on the other, and welding them into a slab for the head of the rail. By this arrangement the rail head is made crystalline and not fibrous, as it is only submitted once to the drawing action of the rolls. After being squeezed or hammered, the iron is passed through the rolls, and leaves them as No. 1 iron or puddle bar, which is cut by shears into the lengths necessary for the subsequent pile. There are different

* Extracted from the *Mechanic's Magazine*.

methods of making the various piles for rails, &c., the great object in piling being to get the pile as solid as possible, and free from interstices. Piles are frequently made of puddle bar of different widths, piled alternately so as to break joint. In some instances the puddle bar is cut into short lengths, equal to the width of the pile, and each layer piled at right angles to the previous one. The object of this arrangement is to make the iron less fibrous, and it certainly has that tendency.

There are various sections of rail in use, but the three most general are the double-headed rail, the bridge rail, and the American or contractors' rail. The double-headed rail is generally made with slabs at the top and bottom of the rail; which for the best quality of rails are about 2in. in thickness, and the rails are double-headed. In some instances these rails are made of three hammered slabs piled on each other. In rolling the American, or flange-rail, as it is also called, a particular description of cold short iron is made for the flanges to stand the strain that necessarily arises from the rails being rolled edgewise, and the flanges not travelling at the same speed (from the less periphery of the rails) lest the flange portion of the rail also should slip. Partially on this account, then, and partially on account of the flange becoming colder than the mass of the rail, it is difficult to obtain a perfect flange unless a peculiar description of iron is used. This iron is made generally with forge cinders and Welsh ironstone without any red ore. The bridge rail is rolled flat—head up and down—and in this example the iron is only likely to rip by becoming cold, and is submitted to far less strain than in the flange rail. In the common sort of American rails the slabs for the heads are frequently made not more than $\frac{1}{4}$ in. thick, and the rails are only single-headed. Single-headed rails require on an average about 12 cwt. of coals to the ton, and double-headed about 16 cwt. The readiest method of ascertaining the way in which a rail has been piled and the thickness of top slab for the head consists in filing a section of the rail smooth and applying dilute mineral acid to the surface. By this means the iron becomes dissolved and the cinder in the welds or joints is left intact. The strains to which rails are subject differ greatly from those imposed upon most other descriptions of manufactured iron. It therefore follows that fibrous iron, such as is used for making cable bolt, is not adapted for them, as, owing to the iron being too soft, the rails soon begin to laminate, and strips or ribbons pare off. Various means have been adopted to make iron crystalline and hard. As a rule, the more iron is rolled the more fibrous it becomes up to a certain point, and for this reason many engineers have the slabs for the heads of the rails hammered so that they may only be submitted to the drawing action of the rolls once. It has been found that by smelting the oolitic iron ores with a mixture of a cinder and clay ironstone, a peculiar description of cold short crystallized iron is produced, and this iron has been very largely used in the manufacture of heads of rails. To the phosphorus accompanying the oolitic ores this iron owes its peculiar characteristics; phosphorus having the property of making the iron, with which it is alloyed, work soft and cold short. Rails made with this iron have been used on lines of railway with success. Although this iron is hard it is nevertheless somewhat weak, and as a hard strong iron can be made with equal advantage by the use of manganese, it follows that this is a preferable ingredient to phosphorus, which reduces the strength of the iron.

GAS REGULATOR.

A very large item in the working expenses of our railway companies is made up of the charge for lighting by gas at the stations, warehouses, and offices. A few days since we had an opportunity of inspecting a very simple, but very efficient apparatus, by which a saving of at least 10 per cent. in the consumption of gas may be certainly effected. The instrument consists of a self-acting regulator, by which the pressure of the gas is made to act directly on a moveable drum, which, just as it is raised or depressed by the pressure, regulates the quantity delivered for consumption. The plan is so exceedingly simple, so inexpensive, and so little liable to get out of order, that it can be applied with great facility by any consumers of gas, whether in large or small quantities. The Great Northern Railway has already adopted the invention very extensively, and have found good reason to be thoroughly satisfied with the result obtained. The apparatus may be seen in action at Mr. Hulett's, gas-fitter, of Holborn. We may add that it may be fitted to any meter without difficulty, and, as we have said already, it not only regulates, but very considerably economises the consumption of gas.

THE ENGLISH MECHANIC.

Every Tuesday, One Penny. Monthly Parts, 5d. Now Publishing, complete, the First Volume. * * * Title Page and Index, One Penny. Cases for binding, One Shilling and Sixpence. It is solicited that all back Numbers be ordered at once.

All the early Numbers have been reprinted. It is therefore necessary that sets be made up at once, as there will be no further reprints owing to the great expense they entail.

147, FLEET-STREET, LONDON, and all Booksellers.

OUR MONTHLY PARTS.

Part 8 of THE ENGLISH MECHANIC, in coloured wrapper, is now ready.

Price 6d. only! Post free, 7d.

All back Nos. have been reprinted, and can be had direct from our Office, or through any bookseller.

A Christmas Present or New Year's Gift for the Apprentice or Improver!

Now Publishing THE FIRST VOLUME

of

THE ENGLISH MECHANIC.

A Record of Mechanical Invention, Scientific, and Industrial Progress.

UPWARDS OF ONE HUNDRED ILLUSTRATIONS.

Hundreds of Useful Recipes, and Thousands of Hints useful to Old and Young in all Trades and Professions.

Handsomely bound only 4s. 6d.; post free, 5s. OFFICE, 147, FLEET-STREET, LONDON, and all Booksellers.

TO ADVERTISERS.

As the ENGLISH MECHANIC addresses itself to the largest and most intelligent portion of the community, and is the only Paper of the kind established, it offers unusual advantages as an advertising medium.

OUR CHRISTMAS NUMBER.

In announcing his intention to publish an enlarged Edition of THE ENGLISH MECHANIC as a Christmas Number, TO BE ISSUED ON THE FIRST TUESDAY IN JANUARY, WITHOUT ANY INCREASE IN PRICE, the Proprietor respectfully submits that he thereby affords the many thousands of readers and numerous contributors an opportunity of each contributing a something as a Christmas and New Year's Treat for his fellows—some little "trick of trade" (in the good and true sense of the word); some improvement in tools, anything, in fact, which may be of value to brother workmen, and will assist in the promotion of feelings of kindness and good fellowship, which the season is so eminently calculated to call forth. The Editor will not fail on his part, and will be glad to find a hearty response to this challenge to do mutual good.

The English Mechanic.

FRIDAY, DECEMBER 22ND, 1865.

"MUCH WORK AND LITTLE PAY."

THE letter in our journal the other day under this heading has called forth a whole batch of various "stokers and pokers." One correspondent says, "I suppose 'Old Clerk' means that, were the telegraph clerks to strike, a very great commercial panic would ensue. What would be the effect of a strike among the railway engine drivers and firemen throughout the country?" This query calls our attention to the consideration that there is a possibility of such a thing coming to pass. Many years ago—1850, we think—there was a strike among the men employed on the North British line running

into Edinburgh, when the first victims to the cheap labourites were a whole truckful of beautiful pigs; In the Autumn of that year we encountered some dozen of the North British "stokers" in New York, on their way to various eligible situations. Now, were the men to determine on some such a step, we are not aware that they have not right and reason on their side—if there be any of the latter appertaining to the last resort. Folks are kicking at having to work ten hours a day; what would they say at having to work upon an average fifteen, and occasionally eighteen to twenty-one hours, as our railway friends do? And there have been times when these men have gone on for from forty-five to forty-seven hours. At the present time there are, we are told, trains running out of York which, under ordinary circumstances (a "good trip"), require the men to be seventeen or eighteen hours on duty, exposed to all weathers; and North Eastern men, it is affirmed, are exposed to rougher weather than any other men in the kingdom, owing to a little lack of humanity—covering the foot-plate, on Mr. Sturrock's plan, adopted on the Great Northern. Did travellers know of the long hours "stokers and pokers" had to work, we are inclined to think they might feel a little more trepidation than they now do. "I know from experience," writes an engine driver, "that men get unwatchful, after working long hours; and men have been known to sleep upon their engines when running at forty or fifty miles an hour." Another one says, "I should wish it more widely known than in their own circle that the two men who have under their charge the lives of perhaps fifty or one hundred of their fellow beings receive—engine drivers, 4s. 6d. to 7s. per day, and firemen, 3s. to 3s. 6d. Respecting drivers, it should be stated that there are very few at the latter figure now-a-days, they that have it have been in their present service perhaps twenty years; and as the old hands die off, their places are filled by 5s. or 6s. per day men. Further, the firemen begin at 15s. per week, and after having been firing for ten years, waiting for the engine which is never given him, he may attain to 3s. 6d. for a day of fifteen hours!" This may be overstated, or it may not. We give it as it is given; and yet, if it be true, we record what is a disgrace and a shame to any railway company. One man says, "whenever a new top-sawyer comes on he lops off 3d. here and 3d. there, so as to reduce the cost of each train mile, and make a show for himself." Says another, "I have seen drivers for whom I have been firing so beat that they dare not sit down for fear of going to sleep, and obliged to keep bathing their eyes to keep awake; I myself have been so overworked that, through sheer exhaustion, I have dropped down asleep on the foot-plate. Can you wonder then that a red light should be run past by men in such a condition?"

We know perfectly well that, despite carrying a whole train full of "preventives" against accidents—lockers full of detonating signals, rows of lamps, a whole peal of bells, half a dozen brake-vans, &c., &c.—they are as nothing if we have not wide-awake intelligence on the foot-plate. We respectfully suggest, therefore, that it would be as well to alter the existing state of things; to add a trifle more to the running expenses, and reduce the hours of labour for both driver and fireman—making these regular, either by day or by night. And, we have no doubt, leaving justice, good feeling, and Christianity out of the question, that the investment would be a paying one.

ON THE ENGINEER'S SLIDE RULE.*

(Concluded from page 135.)

The next portion of the table of gauge points is intended for finding the areas of those regular figures which have from five to twelve sides, and which are generally termed polygons. Of these, the hexagon and octagon, having respectively six and eight sides, are most familiar to mechanics, and though a case would rarely occur in which their measurement would be necessary, it is as well to know something about them. The gauge points given on the rule are the areas of each of the figures when the side is one in length, and since the areas of all similar figures are to each other as the squares of the like sides, it is evident that the lines C and D must determine all questions relative to these figures, hence the rule becomes:—

Set the gauge point of the given figure on C to 10 on D, and against the length of the side on D is the area on C. Thus, required the area of a pentagon, the side of which is six inches. Set 1.72 on C to 10 on D, and against 6 on D, is 61.9 square inches on C.

A still more important, because more generally used figure, the circle, is next brought under con-

* Contributed by Mr. W. Tonkes.

sideration, and on the rule six gauge points are given for finding the properties of this figure, and the relation it bears to the square.

1st. The area. The gauge point is here .7854, because when the diameter of a circle is one, its area is nearly .7854, and for the same reason as that assigned when treating of polygons, viz. — that the areas of all similar plane figures are to each other in the duplicate ratio of their like sides, it follows that the lines C and D must also be used for finding the areas of circles, hence the rule becomes—

Set .7854 upon C to 1 or 10 upon D, and against any diameter upon D is the area upon C.

2nd. When the circumference is one, the area of a circle is .0795, consequently, when the circumference is known and the area sought, we take .0795 as a gauge point, and proceed as in the last case.

3rd. It is well known that if the diameter of a circle is one, the circumference will be very nearly 3.1416, and this number therefore forms the gauge point when the diameter is given to find the circumference, and as the case simply involves multiplication, the lines A and B only are used, and the rule is set 3.1416 upon A to 1 upon B, and against any diameter upon B, will be found the circumference upon A. It is also known that the ratio 7 : 22 represents very nearly the ratio of the diameter to the circumference; hence the same results will be obtained if we work by the rule given for proportion, viz. —

Set 22 on A to 7 on B, then against any diameter on B is the circumference on A.

This method is preferable to the former, because 7 and 22 are whole numbers, and consisting only of one and two figures are more readily found, and the slide more easily and accurately set than with the gauge point 3.1416.

4th. If we wish to find the side of a square equal in area to a given circle, it has been shown that .7854 is the area of a circle when the diameter is one, and hence the square root of .7854 would be the side of the square sought, if the diameter was unity, and this root, viz. : .886, is consequently the gauge point required in this case, if therefore, we set 1 on A to .886 upon B, then against any diameter upon A is the side of the square upon B.

5th. It can be shown that the greatest square that can be inscribed in a circle, the diameter of which is unity, has its side equal to $N\sqrt{2}$ —.707 nearly, hence this number becomes the gauge point when the greatest square that can be inscribed in any circle is sought, and the case becomes one of simple multiplication as the preceding is, but for some reason not explained, Mr. Routledge, and, I believe, all who have made his rules gives the reciprocal of this number, viz. : 1.4142 as the gauge point on the rule, while they give the correct number .707 in the book of instructions. The difference in manipulation will be, that if we take .707 it must be found on B, and placed against 1 on A, but if we take 1.4142 it must be found on A, and placed against 1 on B, in either case against any diameter on A will be found the side required on B.

6th and last, To find the side of an equilateral triangle inscribed in a given circle. This, where the diameter is 1, can easily be proved— $\frac{1}{2}V3$ —.866, and here again we find the reciprocal—1.15 substituted on the rule as the gauge point, requiring the same change in the mode of operating as indicated in the last case.

The remaining portion of the table of gauge points marked on the rule is for the purpose of finding the diameters of cylinders of steam engines capable of working pumps of variable diameters and depths.

This table was evidently formed when the steam engine was in its infancy and its energies directed principally to the drainage of mines, since it deals only with the earliest productions of Watts' genius, the atmospheric engine with balanced beam and 7 lbs. pressure of steam, as a motive power, a simple pair of scales with alternately preponderating weights placed in the pans.

I might with good grace have omitted entering into a definition of this portion of the subject, but as I should thereby have left one portion of the slide rule unexplained, I preferred investigating it, in order to show that although modern improvements have rendered this table practically useless, this circumstance does not for a moment derogate from the almost infinite applicability of the simple instrument under consideration.

The gauge points in the table represent the weight of water contained in a cylinder of any of the diameters specified, and one yard long, divided by the pressure intended to be applied to the piston of the engine that is to raise it, and since this pressure is considered constant, viz.—7 lbs per square inch, it follows that if we multiply the gauge point by the

depth of the pump in yards, the square root of the product will give the diameter of the cylinder required; or, set the gauge point on A to 1 on B, and against the depth in yards on C, is the diameter of cylinder upon D.

So far my remarks have been strictly confined to the engineer's slide rule, but there is another somewhat resembling it, very often used by mechanics, generally known as the "Carpenter's slide rule," from the fact that nearly all the gauge points marked upon it are intended for the measurement of timber.

On this rule the line D is numbered from 4 to 40 instead of from 1 to 10, hence in calculating by it, as the lines C and D have the ratio of the square to it, not to each other, so the gauge points previously given must vary proportionately, hence to make the table of gauge points on the engineer's rule applicable to the carpenter's rule they must be multiplied by the square of $\frac{1}{4}$ —1.16—.0625, and with a table so formed, all the foregoing operations can be as readily performed with one rule as with the other.

WM. TONKES.

THE ENGLISH MECHANIC.—HIS RISE AND PROGRESS.*

(Concluded from page 140.)

On some occasions invidious comparisons have been instituted between this Society and others of a cognate character, which have come into existence since the birth of our own. It has been said that those societies, though younger, have greater numerical strength. I have only to urge in reply to this, that the growth of an institution, the ordinary membership of which is positively limited by the qualification of holding a particular part for a particular period—in our case that of foremanship for two years prior to candidature—the growth of such an institution must of necessity be slow. We cannot gather fruit where none is growing, and foremen engineers of two years' standing are by no means as plentiful as blackberries in September. Other circumstances might be taken into account in this case, but it is scarcely requisite to enumerate them. It is sufficient to say that if our growth has been slow—as with a tree grown on rocky soil—there is toughness and strength in our texture, our fibres are closely knit, and no slight gale will even shake the fabric which it has taken twelve years to rear, much less to destroy it. Comparisons, however, are generally disagreeable, and they are especially so in this instance, where they have been based on imperfect data. The societies to which reference has been made, for which I entertain much respect, and which are effecting a great amount of intellectual good for their members, rest on a base totally different to ours. They appeal to a large and comparatively indiscriminate section of the engineering community, and consequently have a far wider field of operations open to them. They have not the concrete foundation of philanthropy and science to support their superstructure, as we have; they confer no directly material benefit upon associates as we do; and, in short, there are few points upon which fair comparisons may be instituted at all between their characteristics and those of this society. They have their influence—let us hope that our own exertions have not been destitute of that valuable characteristic. There can be no jealousy between us and them. If the number of their members increases with more rapidity than that of this association, so much the better for them, but certainly none the worse is it for us. Those societies are co-workers, not rivals, and cannot be regarded in any other light. In their success, therefore, we rejoice, assured as we are that the whole of the engineering community must benefit by their labours.

I should not have touched upon this subject at all but that others have in a measure compelled me to do so by their rather sharp criticisms of the proceedings of the Associated Foremen. Criticisms, when not ill-natured, are not unwholesome. It is well to have a friend, or even an enemy, candid enough to point out real or imaginary faults; it incites to self-examination, and results frequently in self-improvement. Let us, then, endeavour to profit by looking into the critic's mirror, and tracing on its bright surface any defects which may mar our features, endeavour to correct them, not by the use of flattering cosmetics, but by inward purification—which is more lasting and much more satisfactory in its effects.

I fear that my remarks this evening may seem desultory, and, to some extent, apart from my subject. If they are so, and become tiresome, I must throw myself on the generosity of my listeners. As in the

theatrical world an actor of very moderate ability sometimes is obliged to undertake a part "at very short notice," and which should have been played by a more distinguished man, so have I on this occasion undertaken to play a part for which I was unprepared, and to occupy the place of a much more eminent actor.

It might have been expected that I should have produced some statistical information in regard to the association, but there were two reasons against that course: the first, lack of time; the second, because it was imagined that it would be better to reserve them for the ensuing anniversary, as a more fitting occasion for their production. If I am asked why I ventured upon such a theme at all as that of ourselves and our own institution, I am unable to answer the question, except by saying that no other presented itself capable of being dealt with in the limited time at my disposal; and even this has been but the more imperfectly treated from lack of time. It would have been possible to have reviewed the progress—the incredible progress—which has been made in engineering, and in the mechanical arts in this country during the last few years, and to have shown that much of that progress is due to the untiring but unobtrusive exertions of foremen engineers. The wondrous extension of the railway system, which is transforming every feature of the metropolis—and in some cases, it must be admitted, not improving those features—might have been expatiated upon. The re-construction of our steam navy, and the conversion of engineers into ship-builders and artillerymen, might have been legitimately alluded to, for in these changes the foreman engineer has played no inconsiderable part. These and many other questions might have been appropriately enough embraced in the subject of this paper had it fallen into abler hands, or had more time been at the disposal of the writer. I have only, as it were, skimmed the surface of the water, and left its depths unsounded, its bed unmapped.

Great, however, as has been the labour and the usefulness of the foreman of the past, much more will be required of him in the future. The development of every branch of mechanical industry on the Continent, the vast improvement in the quality of foreign workmanship, and the removal, on our parts at least, of all commercial restrictions, bring the mechanic and the artisan of this country face to face with a competition keen in its nature and excessive in its proportions. It is only by a combination of superior circumstances that we can hope to stem the opposing tide. Those circumstances are, to a great extent, within our own control. There must be a complete understanding between the employer and the employed. It is the duty of the first to remove every real disability under which the workman labours, and it is the duty of the latter to co-operate cordially with his master in his attempts to achieve excellence and to maintain the fame of English operative art. The intermediate agent has a yet more difficult task before him. The foreman must so comport himself as to obtain and preserve the confidence of both master and workman, and to direct the skill of the subordinate into the most efficient and economical channels. In order to effect this, he must make himself yet more completely competent in the knowledge of his profession, yet more zealous in his intellectual studies, and yet more determined to keep pace in the onward march of mechanical discovery. By such means, and by such means only, can England hope to hold her own in the competitive struggle for manufacturing supremacy which is daily becoming more intensified and more obstinate.

It is the mission of such associations as our own to assist in this important work. In these miniature scientific parliaments debates on mechanical problems, engineering practice and theory, and on new inventions and discoveries, are the staple material which we have to seek for and to encourage. I, for one, have full faith in the success of the mission of such societies. It is practically impossible for foremen to attend their meetings without becoming in all ways better qualified for the performance of their especial duties, and more considerate controllers of the work-people under their direction. On all hands, then, and for every reason, associations like our own demand countenance and support; but when each member shall exert himself in the way indicated, this association, I am assured, will obtain both. Let us, therefore, while admitting the impossibility of commanding success, do more—let us deserve it.

My self-imposed task now approaches its termination, and probably you are not sorry that it does so. Like many other tasks I have undertaken in my time, it does not, when completed, satisfy myself. The execution has fallen far short of the conception; and probably I may, with some justice, be charged with lecturing my brother-members instead of delivering to

* A paper read by Mr. Joseph Newton before the London Association of Foremen Engineers, November 4th, 1865.

them a lecture. You will at least, I know from past experience, be generous enough to give me credit for good intentions, and to pardon my failure in this case to realise them. It seemed to me that it was not an improper thing to "take stock" as it were of ourselves and our association, and to endeavour thus to arrive at an approximate estimate of our own position and its usefulness. Were our society of no more service than to make individuals in similar positions, with similar cares and anxieties, labouring under similar difficulties, and pleased by similar circumstances, personally acquainted with each other, and personally interested in each other's welfare, it would be entitled to commendation; but, as I have endeavoured to show, it does much more than this. The London Association of Foremen Engineers is a moral and intellectual lever which, properly applied, cannot fail to elevate its members, and to place them on an eminence far higher than that attained by non-associates, and thus to increase not only their own self-respect, but the esteem in which they are held by the world at large. I need not say to its own members that it essays also to relieve the pressure of their physical ills, to provide for them a solace when the lamp of life grows dim, and to comfort their families when that lamp is extinguished. It is well that these latter characteristics adorn the society, for one cannot, as an old writer has said, help putting little trust in the friendship of the world:—"When I see leaves drop from their trees, just such, think I, is the friendship of the world. While the sap of maintenance lasts my friends swarm in abundance, but in the winter of my need they leave me naked. He is a happy man who hath a true friend at his need; but he is more truly happy who hath no need of a friend."

Considerable applause followed the conclusion of the paper, and Messrs. Sanson, Briggs, Oubridge, Fishwick, and others having spoken approvingly of it, a vote of thanks was awarded unanimously to its reader. Mr. Newton's brief acknowledgment of the vote concluded the proceedings.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents.]

In the absence of any reference to the engraving which illustrates your article on "The Royal Observatory at Greenwich," your readers might naturally imagine that it represented the transit circle described in the text. This is not the case. It is a likeness, and a faithful one, of the altazimuth instrument, which is erected in the new south dome, upon the site of Flamsteed's mural arc.

A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.
December 13, 1865

A PHOTOGRAPHER IN A FIX.

Sir,—Can any of your photographic readers lend me a helping hand in a great perplexity? If so, I shall feel myself greatly indebted to them for their help, and to your valuable paper as the medium through which their assistance is conveyed to me.

I am an amateur photographer, and have, I believe, attained some proficiency in that interesting science, both in the landscape and portrait branches, but one thing is a great drawback to me, which I will explain.

I use the "Eagle" albumenised paper, sold by Messrs. Squire and Co., and which, according to the instructions given with it, only require a 40 grain solution of nitrate to sensitise it.

Now I find that when I have floated two or three papers, these afterwards sensitised are, when taken from the bath of a muddy colour here and there, intersected by broad streaks of white or if not exactly in this state, are covered with black fringes resembling clouds. This paper does well for prints in which there is not much white, as in this case the discolouration does not show, and partially goes off in the subsequent processes, but for vignettes or for negatives, in which portions have been blocked out, it is of no use at all. I filter the bath, and I use kaolin, but in vain; the first two or three papers come out clean, and the rest invariably spoiled.

R. J. ATCHLEY.

CONCRETE COTTAGES.

Sir,—As I read of frequent meetings being held for the purpose of considering the best and cheapest method of erecting cottage dwellings, I trust, as you have admitted into your columns an account of a cheap brick costing 15s. per 1,000, you will give publicity to the fact that Mr. Tall, the patentee, is now constructing two houses in concrete at Bexley-heath. This mode of building has been long known. Concrete is of great antiquity, still Mr. Tall can build at one half the cost of brick and mortar.

H. J. L.

SILVERING MIRRORS AND GLASS BALLS.

Sir,—In an article entitled "Silvering Mirrors," in your number of December 5th, three descriptions are given, and amongst them mine is mentioned. Being happy to co-operate with Mr. V. C. Davis to assist persons desirous to silver any kind of glass, I hope, as I give all the necessary information he will excuse my correcting the errors his letter contains.

It is not Drayton's process which is now practised successfully at Paris, it is mine, and on a large scale, under the firm of Brossette and Co., the Co. being myself. My process is now practised successfully in England, Belgium, Russia, Germany, Switzerland, &c. It is as follows:—

Two solutions are first prepared, one is made of nitrate of silver, 100 grains, by instance, treated with 63 grains of strong solution of ammonia, and after with 4.0 grains of distilled water. On the other hand, 100 grains (to name a quantity) of tartaric acid are dissolved in 650 grains of distilled water. This solution must be kept, and exposed to the light some time before using. To prepare, then, the liquid to silver glass, take, for example, ten cubic inches of the above solution of silver to which you add 2.0 cubic inches of distilled water, keeping good agitation, when you pour into it one cubic inch of the solution of tartaric acid.

The glass is well cleaned, first, with a cloth and whiten- ing, after which a plug of cotton dipped in the silvering liquid, and a little putty powder is carefully passed over the surface to be silvered, and when this application is dry, it is removed with a chamois leather, after being well rubbed and washed with another chamois leather, perfectly clean, wetted with distilled water. The glass is then laid upon a cast-iron table box, heated to about 140° Fahr., and well covered with a layer of about the 1.10th of an inch in depth, which easily stands upon it. In about 25 minutes a uniform opaque coat is deposited. The glass is then tilted, that the liquid may run off, washed with water, dried, varnished, and painted.

To silver balls, the primary cleaning of the glass is obtained by pouring into them a very weak solution of fluoridic acid, and well shaking it about, then rinsing it several times with distilled water. Taving now the silvering solution, about a fifth part of what the ball would contain is poured into it, and the ball rolled about in hot water for about twenty minutes. The operation is repeated to obtain a more thick coated surface.

Naturally, to ensure perfection, a great deal of practice is required, as in many other professions.

I trust now, in comparing Mr. Drayton's method with the simplicity and small cost of mine, Mr. V. C. Davis will, with a little reflection, understand the reason of my process being practised successfully.

T. PETITJEAN.
22, Hornsey-street, Holloway-road, London,
December 11th, 1865

P.S.—I must add that I had the honour of my process being made the subject of a lecture by Professor Faraday, in 1856.

OUR SUBSCRIBERS' NOTES AND QUERIES.

BLASTING.—Can any one tell me how to use the magneto-electric machine for blasting purposes?—JOHN PROULOCK.

MICROSCOPE.—Will any subscriber tell me how to make a cheap microscope? I am much delighted with the directions for a cheap telescope.—RIGGUS.

Will any reader inform me how to find the logarithm of any number less than 10, without the aid of tables, 10 being the base of the system?—W. H. J. P.

TELESCOPE GLASSES.—Will an Economic Artizan inform me where telescope glasses can be procured in Glasgow?—A TIN PLATE WORKER.

GAS.—Can any reader inform me, 1st, the cause and cure of water in gas-pipes laid in the house to supply the fittings? 2nd, to take the black spots out of lacquered gas fittings preparatory to relacquering? 3rd, how to do the Florentine bronze?—JOHANNES.

IVORY BRAIN.—What preparation will stain ivory billiard balls any colour effectively?—J. SIMPSON.

HYDRAULIC.—A hydraulic water ram is fixed so that there is ten feet perpendicular fall from the head of water to the ram—the length of pipe from head of water to the ram is 30 feet. Required the height to which the water will be raised, and in what proportion is the quantity raised to the quantity wasted, and if the length of pipe through which the water is forced will make any difference in height? If any correspondent will inform me upon it, I should feel obliged.—HYDRAULIC.

LATHE.—Can any reader inform me where I can obtain the iron work for the lathe described in No. 36, Page 116.—HYSSOP.

FEET SAW.—In your impression of the 24th ult. a Mr. Merritt gives a description of a feet saw. Does your correspondent think that his design would be applicable for cutting felices, &c.? Perhaps he would not think it too much trouble to give a more detailed description of one; or perhaps some other one of your numerous correspondents would give their idea of a saw for cutting felices, centerings, &c.?—WHELEWRIGHT.

GALVANIC BATTERY.—Will any reader inform me of any cheap little work on the construction of a galvanic battery?—J. W. BENNETT.

SYPHON ACTION.—I have a syphon fixed to draw water from a cistern, the long leg is 3 feet below the water. The cistern ran empty, and I drew all the water from the syphon. The cistern filled again, and, without removing the air from the syphon, I can draw about half the full stream. After drawing out the air the syphon acts properly, but after blowing the water back into the cistern the water drops a few minutes, and then begins running slowly, as before. Can any of your readers explain in this?—K. H.

OVAL CHUCK.—Will Cuccino inform me how I can make an oval chuck for a small lathe, to turn and set oval settings for small work?—G. H. D.

SPINNING.—Can any reader oblige me with a description of an ordinary spinning wheel, such as is used in the northern counties of England, or where I can buy one in London?—CALUM PRIS.

Can any reader inform me how to calculate the horse-power of stationary engines—for instance, say, a cylinder 60 inches diameter, 2 feet 8 inches stroke, what is its power? What is the difference in calculating condensers, and high pressure?—COLLEA.

TRANSFERRING.—Will any of your readers inform me of a method of printing from pencil drawings? There is some certain method of making the pencil marks only take ink like a lithographic stone, &c. How can I make transfer fluid for the purpose of transferring wood-cuts to paper, glass, &c.?—E. GAR.

COPPER.—It is a curious fact that when copper is made into forgings, the weight of the work produced, together with the scraps cut off, is greater than the original weight of rough copper. Perhaps carbon is absorbed by the metal from the coals of the fire, which causes this strange phenomenon. Does it occur in any other metal, and what is the cause of it?—CYCLOPS.

SMEE'S BATTERY.—I have just constructed a Smee's battery, and use for my cells some earthenware dishes, 6 inches wide by 8 inches deep, and, although they are glazed over, the acid finds its way through the cells, destroying whatever may be in its way. Will some one kindly inform me how I may prevent the acid from escaping from the vessels, or if wax varnish would adhere to the cells without cracking off?—GULLIVER.

A DIAMOND FOR CUTTING GLASS CIRCULAR.—Will any correspondent inform me where I can get one in London?—SILKX.

P.S.—I have your first number of the "Mirror of Science" before me, and I hope you will excuse my candour when I say I consider the MECHANIC of the two is the best value, but I hope the "Mirror" will improve; but I must say the first number is very meagre. I say this in good faith, not as an often-ive criticism.—SILKX.

HOLTZPFFER'S 4TH VOLUME.—Is this ever to be issued? The amateur mechanical world have been anxiously expecting it for years. Possessing the others, I would give almost its weight in silver for it. A notice in the preface of one of the published volumes says it is even partly in type, and that volume dates several years back.—G. E. C.

TELESOPES.—Will an Economic Artizan tell me at what apertures I can get, for about 4s., a 35-inch object glass and a 1-inch eye-glass, and whether the image will be chromatic or not?—G. E. C.

CHUCK.—Will any correspondent tell me how to make a chuck to cut circlolds to ornament work in the lathe?—S. D. S.

ELECTRICAL MACHINE.—Having seen described in your magazine (No. 11, Vol I) an electrical machine, I wish the correspondent would let me know where I can procure a cylinder of the size mentioned, viz., 6 inches by 4 inches? Would it answer to mix amalgam in a crucible, or would the mixture stick to the sides?—QUICKSILVER.

MAGIC LANTERN.—Will any of your readers oblige me by a description of the lines used in a powerful magic lantern, their diameter and focal strength?—W. R.

REPLIES TO QUERIES.

PRESSURE IN BOILERS.—I quite agree with J. S. when he states in your impression of the 1st that G. S. appears to be incorrect, but think he is far from being correct himself; in my opinion it should be as follows:—

Let a = length between weight and standard.
 b = do. valve, spindle, and standard.
 c = weight in lbs
 e = action of weight of lever and valve.
 $a + b \times c + e$ = weight on d .

Should J. S. or G. S. consider me incorrect, I should be much pleased to hear from them again.—R. P.

ENAMEL DISCS.—In reply to Electric, in No. 37, I believe Silvers', Bishopsgate-street, are the only manufacturers of enamel discs. Price about (for a 12in.), 7s. or 8s.—the ordinary rubber.—O. K.

BROZING.—In reply to B. Kingsland, I beg to inform him I use the following methods for bronzing electrolyte medals, which no doubt will be of service to him.

Brown.—Add to a wine glass of water four or five drops of nitric acid, with this wet the medal, allow it to dry, impart a gradual heat, by which the surface will be darkened in proportion to the time exposed.

Black.—Wash over the medal with sulphuret of ammonia, which should be dilute, dry with a gentle heat, polish with a hard hair brush.

Green.—Steep a few days in strong solution of common table salt, wash in water, and allow to dry slowly. A beautiful bronze, and very permanent.—H. MOUTON.

SMEE'S BATTERY.—Can any reader tell me what sort of cotton and silk is used for covering copper wire, and where in London I could get it best and cheapest? The following is an excellent substitute for the silver plates in Smee's battery, and has the advantage of cheapness. I have not seen it mentioned anywhere, and think it might be useful to some of your electrical readers.—Get an old saw—a stout pit saw in preference—soften it in a smith's forge, and cut the plates the required size, then insert them in the heart of a clear coke fire, giving it sufficient draught to raise them to a white heat, then take them out and hammer them flat with as little violence as possible, and allow to cool gradually, they are then fit for use; attach a wire or binding screw to one end, and arrange as in Smee's battery. I prepare mine in the furnace of a conical boiler used for heating a greenhouse, which I find well adapted for the purpose.—A PRACTICAL GARDENER.

SAFETY VALVE.—In answer to Wm. Tones, in No. 37 of THE MECHANIC, I think the following will be found correct. Multiply the weight upon the lever by the distance in inches to the fulcrum, and divide the product by the distance between the fulcrum and the valve, and the quotient,

the weight of valve and effective weight of lever, equals pressure on the whole valve, and that divided by the no. of square inches the valve contains, equals pressure per square inch. Thus, suppose a valve and attachments of the following dimensions:—

Length of lever = 14 inches.
Weight of lever = 2.5 lbs.
Weight of valve = 1.5 lbs.
Diameter of valve = 2 inches.
Distance of valve from the fulcrum = 2 inches.
Weight to be suspended on lever = 20 lbs., and to be placed 12 inches from the fulcrum.

Half the length of lever multiplied by its weight and divided by the distance from the fulcrum to the valve equals effective weight of lever.

Thus $7 \times 2.5 = 17.5$, weight of valve and

effective weight of lever.

When $20 \times 12 = 240$, $\frac{17.5}{240} = .0729$, $132.25 \times .0729 = 9.64$ lbs.

Pressure per square inch. — E. FARNSWORTH.

ADDRESS WANTED.—I beg to thank Old Charlie, and Master Turner, would feel obliged for the former's address.—SATELLITE.

A. Plaisance Cottages, Jersey.

STEAM PRESSURE.—The pressure got on pistons about 10 lb. and cut off at 2/3rds of the stroke; the diameter of cylinders 26 inches; length of stroke 5 ft.; revolutions of shaft per minute 49; diameter of oscillating cylinders, 20 inches; pressure expected to work 60 lbs. My best thanks to A. Stokes, and others of your correspondents.—B. D. D.

GUILLAUME.—I don't know of any cheap and easy method of vulcanizing india-rubber. 2. Dental rubber, as supplied from the manufacturers, is perfectly plastic. 3. It is rendered fit for moulding by heating on a hot-water plate, and when moulded, moulds and all are put into a vulcaniser, and exposed to superheated steam for 2 hours, when the models become perfectly hard.—G. E. C.

INLAYING.—About three numbers since, a correspondent inquired for fancy inlaid lines for tables. I can supply him with any kind of inlaying.—A. T. MERRICK.

J. Eaton-place, Wells-street, South Hackney.

CABLE AND MAGNET.—Will Mr. Mulholland let me know the date of his patented "Improvements in Telegraph Cables," made mention of in ENGLISH MECHANIC, No. 30, vol. II?

IN answer to your subscriber's query in No. 36, vol. II., under the name Magnet. I can positively assert, from a long experience, that nothing whatever placed between a magnet and an object influenced by its attractive power will destroy, wholly or partially, the influence of the magnet on such object, except an opposite pole.—VERITAS.

[The above correspondent is the patentee of a mariner's compass to resist the attraction of the iron on board of iron ships. It is now at sea and promises to be a success.]

ELECTRO-MAGNETISM.—I beg to thank Mr. R. W. Willis for his kind and courteous information in reference to the practical trial of my suggestion in your No. 34, to propel ships by means of electro-magnetism, generated by the ships themselves through the means of copper and zinc sheathing.

From experiments made in India some years ago, I was quite aware that the thing was perfectly practicable, and, moreover, that the chemical wear of the metallic surfaces in salt water is very slight indeed.

There is a law of galvanic action which is very imperfectly understood at the present day. In small batteries when you increase the metallic area, you increase the electrical power. This can be calculated up to a certain point. But when you come to hundreds of superficial feet in the case of a ship's sheathing, the power increases in an immense ratio.

All minor difficulties in respect to insulating the plates of copper and zinc, are easily overcome. I believe that in electro-magnetism, we have a motive power at present little thought of, especially at sea, where the chemical excitement is always at hand.

I shall be glad to hear that others carry out the idea. I have so long entertained.—JERO. TAYLOR.

THE DANIELL'S BATTERY, as described by Alfred Crofts would be very intense, but certainly would not work for long with acid, without destroying the zinc; nor do I think his battery calculated to "last constant" any length of time. Such an one as is used in the telegraphic offices would answer his purpose. A box of baked wood, or wood coated with a solution of shella, or resinous substance, divided into ten or 12 cells by plate divisions, all to be quite acid tight, with copper and zinc plates about 5" wide, and 4" deep, one pair in each cell, connected in the usual way, zinc to copper, thus:—

The zinc to be well amalgamated; the acid, 1 sulphuric to 15 water; and is used in the cells, when the battery has to be moved about much, it being well moistened with water.

Have constructed some round Daniell's batteries for telegraphic use, thus:—

C, is a copper cell with brass binding screw; L, is a leather diaphragm with a round piece of wood fitted in the bottom water-tight; Z, is a zinc tube amalgamated, cast hollow right through, with a binding screw attached, put the zinc into the leather and the whole into the copper cell; fill zinc with sulphuric acid diluted, and the copper outside the leather with sulphate of copper nearly to the height of a lid within the leather. I would recommend Mr. Alfred Crofts to Mr. R. W. Sykes, practical electro-mechanic 4 Holly-place, Stockwell, S. E., who will, by private letter, answer any question correctly, as he has done for me before now.—W. HOSKINS.

STEAM WHISTLE.—In answer to Henry Williams, I beg to submit the following, trusting it will give satisfaction:—

Fig. 1 is a section, and fig. 2, elevation. The same letters do for both. The foot A is cast hollow; the flange B, being for the purpose of bolting it to the boiler; the cock C, with the handle D, is screwed tight by the screw E; the piece F, screws upon the foot A, fixing the cup G, so:—

And both are turned truly at their outer edges, leaving a very narrow passage, I, I, between them all round; the piece K, is hollow and has holes H, in its sides; the pillar L, is fixed upon its centre; the bell, L, L, is screwed upon the pillar, the bottom edge of which is very thin, and is made so as to come exactly over the opening I, I, and at about 1/2 inch above it. When the cock is opened to admit steam, the steam rushes through the holes H, and out at the narrow opening I, and strikes the thin edge of the bell L, producing a sharp shrill sound. Some holes S, M, are sometimes made to allow the steam to pass through, which improves the sound considerably. Fig. 2 represents an elevation of the steam whistle, the cock D, being shut.—E. J. WITCHELL.

ANSWERS AND NOTICES TO CORRESPONDENTS AND READERS.

ALL letters intended for the Editor should be addressed to 75, Fleet-street.

LETTERS applying for information to be furnished by post cannot be attended to.

Correspondents are requested to keep copies of their drawings and manuscripts, as the Editor cannot undertake to return such as may be rejected.

GEORGE ADAMS can scarcely be a very attentive reader, since some three or four directions for purifying oil have recently been published in THE MECHANIC.

A. A. GLASGOW.—Write again, and use common writing ink, your letter stuck together and blurred in the folding so as to be quite unreadable.

BURLEIGH.—The greater number in Birmingham. SUBSCRIBER FROM THE BIRMINGHAM.—Often tried, but never with success.

T. E. M.—Try Edgley, Engineer, Lamb's Conduit street, London.

J. J. H.—Write to Mr. H. Laxton, 34, Arundel street, Strand.

H. PIPPOCK.—Write to Munn and Co., Patent agents, New York City, U. S.

DICK POLLARD.—You require more than can be taught by an answer from any of our turning friends; obtain a lesson or two of a practical man.

J. W. HUMPHREYS.—They are very numerous, and differ much in construction; you can obtain a specification at the office of the Commissioners of Patents, Southampton-buildings, Holborn.

EMERALD.—What do you say to Jackson's, in present number?

MAGNETISM.—We have heard of the invention, and when opportunity offers intend to describe it.

R. RUSSELL.—Search back numbers, the question has been answered more than once.

EXTERR.—Try again, mix with a small quantity of size, not a patent.]

LUBRICATOR.—Received.

JOHN MCMURRAY.—Received, but too late, we shall be glad to hear from you again.

E. GAR.—You can obtain the pamphlet for a penny or two-pence.

ROBERT ALEXANDER.—Write again, not received.

THOMAS DUNBAR.—Attended to

J. W. R.—Other drawings will soon appear.

SANDY SLOW.—Why not try the experiment, it is worth the trouble, and is easily managed.

GEORGE UNDERWOOD.—Write to the office of the Commissioners of Patents, Southampton-buildings, Chancery-lane. You will perceive by the notice in THE MECHANIC, that we cannot forward specifications from the office. The authorities refuse to receive postage stamps over the counter.

J. H. M.—Very good.

E. CRICK.—Thanks for your kindness.

ELECTRIC SPARK.—The springs can be re-tempered. 2. Of the publisher only, so far as we know. 3. Not at present.

EDWARD HENDERSON.—We may find space to insert the letter and engraving in the enlarged Christmas number, if you forward them at once.

VERITAS.—Protection only we think.

* * We have to ask our correspondents to sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them by the thousand; and the same with "Well-Wisher," &c.

GENERAL NOTES.

EHRENBURG states that the bog-iron ore of which the Berlin iron castings are made had its origin in living creatures—animalcules, which preserve their vitality even when immersed in the strongest muriatic acid.

It has recently been found that the unctuous clay, overlying the ironstone deposits of the Yorkshire moors in the North Riding, can be made to produce a mineral oil, similar to petroleum, at a cost of 6d. per gallon.

THE NEW BLASTING POWDER.—A comparative trial, extending over upwards of a month, has been made at the Roundwood Tunnel, near Dublin, for the purpose of ascertaining the practical value of Messrs. Schaffer and Budenberg's new blasting powder. With the new powder, the progress made with a driving in No. 1 heading, 6 ft. x 5 ft., was 7 ft. in 168 hours, whilst with the old powder it required 200 hours to drive 4 ft. 5 in. In No. 2 heading, dimensions as before, with the new powder, 5 ft. was driven in 168 hours, whilst with the old powder only 4 ft. were driven in 200 hours. It will thus be seen that 41 per cent. more work was done in 16 per cent. less time.

PETROLEUM AS STEAM-FUEL.—The experimental boiler made in the factory at Woolwich Dockyard, and which has been at work at intervals during the past fifteen months, in testing petroleum, shale, and other oils for steam purposes, to supersede the use of coals, has been given over to the Admiralty authorities by Mr. Richardson on the completion of his experiments, which, it is stated, have thoroughly matured the principle, and rendered his theory a matter beyond doubt. Mr. Richardson has likewise, at their Lordships request, submitted plans for the conversion of the ordinary ships' boilers into boilers for which petroleum can be used. This, it is said, can be done at small cost.

VESSELS composed of iron plates have been employed for more than fifty years in the navigation of canals, but it is not more than twenty-five or twenty-six since they were first introduced as sea-going vessels. It is true that an iron vessel was built in 1820 from designs by the late Mr. Aaron Manby, and navigated from London to Havre, and on to Paris, but this was not a sea-going vessel, but an iron steamer constructed for the Seine.

IMPROVED QUARTZ CRUSHING MACHINERY.—Mr. Andrew Buchanan, of Brooklyn, New York, has invented a machine for quartz-crushing and similar purposes, in which two segments are employed, with smooth or corrugated faces, the said segments being hung on rock shafts or gudgeons, and connected at or near their peripheries to a lever or other suitable device, in such a manner that, by the action of the said lever or other device, a very powerful oscillating motion can be imparted to the segments, and quartz or other materials placed between their faces are crushed with ease and facility. If a lever is used to impart to the segments the desired motion the crushing power can be increased to any desired extent, and the motion of the segment can be easily adapted to the material to be crushed.

From the report of the eighth census it appears that there are seven establishments in the United States for copper rolling. These establishments employ 413 hands, and have a capital invested of 2,470,000 dol. The cost of material consumed by them is valued at 2,537,000 dol.; the cost of labour at 157,080 dol.; and the annual value of products for the year ending 1st of June, 3,198,768 dol.

AGRICULTURAL RAILWAYS.*

Mr. Richard Winder, engineer, 18, Abingdon-street, Westminster, has lately patented an ingenious application of railways to agricultural purposes, more particularly for ploughing and cultivating the land by steam power. He proposes to use a single line of railway (centrally placed) which supports the chief dead weight of the machine that travels across the land; and is the means also, whereby the machine is propelled forward by the spiked pinions described hereafter. The central rail and jointed sleepers also prevent the machine sinking in from the extent of area of bearing surface of the sleepers; hence the power of the engine is wholly available for the work to be done. By this patent it is also intended to make the rail available for helping traction engines up steep inclines, when travelling along the various hilly country roads, by a simple and cheap alteration, and to reduce the dead weight of the machine to a minimum. The engine and boiler frames are made of T-iron; and the bulk of the coals and water will be upon the headland anchors, sufficient being taken upon the machine from time to time to last for one or two journeys across the field from headland to headland. And in comparing this plan with others in present use, it will be seen a single length of chain is only required; which is half the length of the rope of the best plan in present use; all friction, wear and tear, and loss of power of the present moving ropes is done away with, all snatch blocks, rope porters, windlasses, clip drums, and the apparatus for working the same are dispensed with, the headland anchors also are very much simplified; and the power of the engine is best obtained by being always close to its work. To enable our readers to understand the details of this invention we annex the following explanation having reference to the drawings on this page.

The accompanying engravings clearly illustrate the manner in which this invention is carried into effect. Fig. 1 is a side elevation, and fig. 2 a plan of one of the apparatuses complete; fig. 3 is an elevation of the jointed sleepers and flexible central rail showing one of the spiked pulleys working therein; fig. 4 is a plan showing both spiked wheels set out for working the machine forward along the flexible central rail; fig. 5 is an elevation of one of the jointed lengths of the sleepers; fig. 6 is a plan of the same; fig. 7 is an elevation of one double link and one single link of the flexible central rail; fig. 8 is a plan of the same; fig. 9 shows the complete apparatus at work. A A is the central rail formed of links with lateral spaces between them. The rail is fastened by countersunk bolts to the jointed sleepers O, one bolt in the centre of each length of sleeper. It is likewise fastened at each headland to anchors of any simple kind travelling upon wheel or discs, as shown in the view fig. 9, where X X are the anchors. The central rail carries the chief portion of the dead weight of the machine upon the grooved wheels L L L, fig. 1. B B are two pinions or wheels having projections or spikes upon their peripheries. These spikes fit in between the links of the flexible central rail, and being caused to revolve propel the machine forward. C is the main shaft of the machine. D D are the cylinders of the engine. E is the boiler. F F is the steam pipe leading from the boiler to the cylinders. G G are the high wheels that carry a portion of the dead weight of the apparatus when ploughing, and the whole of the weight when it is used as a traction engine; these wheels run loosely upon their axles. H H H are cog wheels which drive the spiked wheels B B by vertical shafts I I. These shafts are fitted with long feathers or keys so that they can work freely up and down through the horizontal cog wheels H H in order to compensate for any unevenness of the ground passed over. The shafts are also coupled together, the coupling having in the centre a right and left hand screw, so that by turning the screw one way the spiked wheels are forced further apart, and thus thrown out of gear with the rail, and by turning it the reverse way the spiked wheels are brought closer together and placed in gear with the sides of the rail, and by screwing together still closer, additional friction is obtained by pressing the wheels against the sides of the flexible rail, and in place of the coupling above described an elastic or spring coupling is sometimes used. K K is the frame of the apparatus made in two parts the more equally to distribute the dead weight to be carried over the land and to allow of its accommodating itself to the inequalities in the surface of the ground. One part of the frame carries the boiler the other part the engine's main shaft and other working parts, L L are the grooved wheels which run on the top of the central rail A. Springs are provided to allow these wheels to adapt themselves

to the unevenness of the ground passed over. M is the grooved pulley on the lower part of the boiler around which the rail may be coiled for transport. This pulley can be made either to take off altogether, or be raised up outside the boiler out of the way when not required for use. It is either worked by a cog wheel attached by a connecting rod to the engine as shown in the engravings, or it can be worked by hand. N is the frame for shifting the central rail and sleepers to the new position ready for the apparatus to travel upon in the return journey. The frames are raised alternately out of the way,

when not in use. S is the cultivator or plough frame fitted with steering apparatus at each end and with rocking bars to which are fixed tines or shares. This implement does not turn at the headlands.

IRON AND ITS COMPOUNDS.

Chemists have for some time been aware that there are two metals which were at first confounded under the term iron; but which, except that they are capable of being converted into one another, are almost as different as

ELEVATION OF

PLAN OF THE MACHINE, AND DETAILS OF

and powered into their work according to which way the machine is travelling. At N, figs. 1, 2, the frame is shown in work, and at N¹ it is shown raised up out of its work. When the apparatus is at work the frame N in work is shifting the central rail at the same time the apparatus is travelling across the field drawing the plough or other implement after it. Upon arriving at the headland this frame N is raised up out of the way, and that on the opposite end of the apparatus is lowered ready to shift the central rail to the required new position while the machine is making the return journey: thus the frames N N¹ are raised and lowered alternately, shifting the rail each time to the required distance sideways until the whole field is finished; neither engine nor any other part of the machine turns at the headlands. O O are jointed sleepers to which the central rail is fastened. Play is left at the joints to allow the sleepers to adapt themselves to the unevenness of the ground. P P are standards and gearing for raising the guide frames N and N¹ when not in use. Q Q are guides fitted with a recess to hold up the end of the guide frame free of the central rail

GENERAL PLAN SHOWING

WINDER'S PATENT SYSTEM

any two other metals with which we are acquainted. It was long supposed that what were termed the proto-salts and per-salts of iron had the very same base, and differed only in the relative quantities they contained of that base; the proportion being 1 to 1 in the proto-salts, and 1 to 1½, or rather—as the existence of a half atom was not to be admitted—of 2 to 3 in the per-salts. The strangely different properties of the two classes of salts, though they always excited attention, did not, until recently, suggest a possibility of their being salts of,

* Extracted from the *Mechanics Magazine*, November 17th 1865.

reality, different bases. This view, however, at as forced itself on the minds of chemists, and has been most universally adopted, the names given by Berzelius the two kinds of iron being everywhere accepted. That distinguished chemist termed the base of the protoxide of iron *ferrosium*, and that of the per-salts *ferricum*—ad, though only allotropic states of the same element, are as different in their properties as the two oxides of phosphorus, or those of sulphur. The atomic weight of *ferrosium* is 28, that of *ferricum* is 56. The atomic heat of the latter is twice that of the former.

with the most important consequences: and may possibly lead to valuable results, in suggesting modifications in the iron manufacture.

Hitherto, the properties of compounds of iron had been considered due merely to the amount of oxidation, or the quantity of carbon, &c., in combination with it. Cast-iron, steel, and wrought iron were believed to differ only in this way; although the fact that difference of property was not always in accordance with difference of chemical constitution constantly obtruded itself: and it ought to have been concluded that chemical composition

its brittleness when combined with carbon.

Ferricum is the metal of the anhydrous per-oxide. It is found pure in the iron obtained from ores containing that oxide: and its characteristic property is its abandonment, during slow cooling, of the carbon with which it combined at a high temperature. It affords malleable iron. By itself it cannot afford stable steel, nor stable white cast iron—at least, by means of metallurgic processes of the ordinary limited duration. Its physical characteristic consists in its malleability, and it loses this only when it attains its ultimate form of blistered iron.

Ferrosium passes easily into the state of *ferricum*, and in that state retains its quality of hardness: hence it will furnish steel and malleable iron. It has the decisive property of being brought, by means of ordinary metallurgic processes, from iron to steel, and from steel to cast iron. On the other hand, *ferricum* cannot be changed into *ferrosium*, unless, perhaps, by very difficult operations: and—when it has been obtained from the compounds of the per-oxide—not so as to be a stable form. If it has been originally *ferrosium*, it may be made so again.

Malleable iron consists of a mixture of *ferrosium* and *ferricum* in various proportions, the *ferrosium* having been changed, at a high temperature, into *ferricum*. Its quality depends on the relative amount of each constituent.

Steel, when stable and of a good kind, consists of *ferrosium* and *ferricum* in the proportions represented by their atomic weights: hence the magnetic oxide of iron, which contains the two oxides in these proportions, furnishes the best kind of steel. It is worthy of remark, that the magnetic oxide and magnetic pyrites—which both contain the two kinds of iron in the proportion of their atomic weights—are, like hardened steel, permanently magnetic.

Black and grey cast iron differ from the white, in consisting of *ferricum*, which retains a part of its peculiar qualities, and which, during slow cooling, abandons the carbon it took up at a high temperature. In grey cast iron, the *ferricum* usually predominates. In the mottled kind, the two irons retain their peculiarities: the *ferrosium*, combined with carbon, forms the white portion, and the *ferricum*, with its deposit of carbon, the dark.

The two kinds of iron remain distinct, and preserve their characteristic properties, however mixed together, during most of the processes to which they are subjected in metallurgy.

The relative amounts of *ferrosium* and *ferricum* in a given product depend not only on the ore whence it has been obtained, but the temperature and re-agents employed in its manufacture. A low temperature favours the presence of *ferrosium*; re-agents, such as phosphorus, which combine with odd numbers of atoms of oxygen, not less than three, favour the production of *ferricum*. The high temperature capable of developing the latter will be required for a shorter time, if re-agents are used in aid of it. When the proportions of *ferrosium* and *ferricum* are due not to the ore, but the temperature, or re-agents, they are in an unstable state: which explains the slow effect of time, and the rapid effect of vibration, in deteriorating axles, &c., so as to render them liable to breakage.

When steel is suddenly cooled the carbon is combined in a stable form with the *ferrosium*, but in an unstable with the *ferricum*. Subsequent tempering separates the carbon from the *ferricum*, and restores the malleability of the latter.

There is reason to suppose that the calorific capacity of iron depends wholly on the relative amounts of the *ferrosium* and *ferricum*. Should this be found to be strictly the case, calorific capacity may yet be used as a simple and effective means of distinguishing the nature and origin of a given specimen of iron.

TIN.—The presence of lead in the tin employed for coating the sheet iron used for cooking utensils may be at once easily detected by filing off about ten grains of the suspected tin coating, boiling it with an excess of nitric acid diluted with three times its weight of water, filtering, and then adding to the clean liquid a crystal of iodide of potassium. Should lead to the amount of only the one ten-thousandth part be present, a yellow precipitate, not re-dissolved by excess of ammonia, will be thrown down.

POTASSIUM is naturally an expensive metal, on account of the troublesome process required for its reduction. It is likely, however, henceforward to be obtained much more easily and economically, as it has been found by Bekeftoff that it may be separated from its compounds by means of aluminium—hydrate of potass being the most convenient for that purpose. Its cost will therefore henceforth depend on that of aluminium.

THE MACHINE.

THE FLEXIBLE RAIL AND JOINTED SLEEPER.

THE MACHINE AT WORK.

OF STEAM CULTIVATION.

Ferrosium combines with one atom of oxygen and other elements, *ferricum* is saturated by not less than three.

The existence of the two bases was considered certain, although only one of them, *ferrosium*, had been obtained; but even this link in the chain of evidence by which their existence may be established, has now been supplied by M. de Cizancourt. In his researches on the subject, lately brought before the Academy of Sciences at Paris, he has afforded information regarding it which, when fully developed, will most probably be attended

performs only a secondary part—the first and most important part being connected with some other circumstance which had not been sufficiently attended to. Specimens of cast iron, of exactly the same composition, are often extremely different, in appearance and qualities; specimens of cast iron and steel are sometimes not to be distinguished by the relative amounts of the constituents; and specimens of steel and malleable iron are occasionally identical in composition.

M. de Cizancourt has ascertained that the difference is, in reality, to be looked for in the sources whence the iron has been obtained—that is, in the degree of oxidation in which it is found in the ore. Each ore furnishes its own peculiar iron; and, by consequence, only certain ores will afford steel or cast iron of certain qualities.

Ferrosium is the metal of the protoxide; it is found, merely combined with a little carbon, in the white crystalline cast iron, which is so easily obtained from ores of the protoxide, and especially the carbonates; and its characteristic property is its reduction at comparatively low temperatures. It is remarkable for its hardness and

SOLDERING.

(Continued from page 140.)

The works requiring to be hard soldered do not differ greatly in their treatment, therefore but few examples are necessary here—though it should be mentioned some nerve and experience are required, as the melting heat of both metal and solder very nearly approach similarity. The hard solders most commonly used are the spelter and silver solders. The general flux is borax, and the modes of heating are—the naked fire, the furnace or muffle, and the blow-pipe, as shown in our last. Fine gold, beat out and cut into shreds, is used for soldering vessels for chemists made of platinum; copper in shreds is sometimes used for iron; gold solders, laminated, are used for gold alloys; spelter solders, granulated whilst hot, are used for iron, copper, brass, gun metal, German silver, &c.; silver solders, laminated, are used for all silver works and for common gold work, also for German silver, gilding metal, iron, steel, brass, gun metal, &c., when extra neatness is required; white or button solders, granulated, are employed for the alloys called button metals.

Several solders contain zinc, which is useful because it increases their fusibility, and where the solder cannot be seen it indicates the completion of the process—for when the solder is melted, the zinc volatilises and burns with the well-known blue-coloured flame; and as just at that instant some zinc is consumed, the alloy remaining becomes tougher, and thus more nearly approaches the condition of the metal it is desired to join. Cleanliness of parts before applying the solder is desirous, though where the red heat is employed this does not matter.

Works in copper, &c., prepared for brazing, either by lap or "nick," the grain spelter and borax powder are mixed in a little water, and the mixture is spread as evenly as possible along the joint to be made. Suppose the work to be made is a pipe, then, before placing on the mixture the end is laid hold of by the plyers, and when all is ready, fire included, the pipe is gently deposited on the coke, the foot inserted in the chain attached to the rocking shaft, and the blast let into the fire. Gradually the water evaporates, then the borax "froths," next it flows quietly, like glass; the fire being now bright, and the pipe red, the solder fuses, and runs into the joint, assisted by a tap or two with a tool—the joint is made in a second, and the pipe pitched into the water, or dipped therein to cool. We have seen a joint made so well, and, withal, so easily as not to require the file.

Tubes, however, are generally secured by hoops of binding wire twisted up; and those soldered upon the open fire are most commonly soldered from within, as, otherwise, the heat would have to be transmitted across the tube with greater risk of melting the work before the solder fused. Locomotive boiler tubes are rested on the flat plate of the brazier's hearth, and portions equal to the extent of the fire are soldered successively. The common Birmingham tubes for bedsteads, gasworks, &c., are soldered from the outside; but, as this is performed in shoot furnaces open at both ends, and level with the floor, the heat is applied more uniformly round the work.

Iron requires less precaution, and there is no risk of fusion. Thus, in soldering spiral wires to form the internal screw in the boxes of ordinary tail-vices, the work is coated with loam, and strips of sheet-brass are used as solder; the fire is kept well up till the blue flame appears at the end of the tube, when fusion is complete; the work is withdrawn from the fire, and rolled backwards and forwards to distribute the solder equally to every part. Locks, &c., are also covered with loam, to prevent the iron scaling off. Sheet-iron, we are informed, may be soldered by filings of soft cast-iron, applied as in soldering with borax, which has been gradually dried in a crucible and powdered, and a solution of sal-ammoniac.

The finest works in iron and steel, and those in brass requiring great neatness, are treated to silver solder, of which very little indeed is required in the hands of a decent workman. The practice is the same as in brazing: the joint is first moistened with borax and water; the solder is then placed on the joint. In heating, care is taken not to displace the solder; for which reason some boil the borax, or drive off its water of crystallisation at red heat, then powder it, and apply it dry along with the solder. Others, again, fuse the borax on the joint before placing on the solder. Many works united with the hard solders—mathematical instruments, jewellery, &c.—are soldered with the blow-pipe; in nearly all cases supported, and sometimes covered with charcoal, for concentrating the heat.

In soldering gold and silver the borax is rubbed on a slate with water, to the consistence of cream, and is laid on the work with a camel-hair pencil and the solder, either in wire, dust, or otherwise applied. In many works such a delicacy has been attained in the application of the solder, that no scraping or filing of edges is necessary, and the borax is removed by immersion in "pickle."

In treating of soft soldering, it may be noticed that the plumbers' sealed solder (two parts lead and one tin) melts at 440° Fahr.; fine tin solder (two parts tin and one lead) melts at 340°; and the bismuth solders at from 250° to 270°; the modes of applying the heat differ much in consequence.

The following table of alloys and their melting heats, fluxes, and modes of applying heat is founded on one drawn up by Mr. De Claubry, all of which will be occasionally referred to by figure and letter throughout this matter:—

FLUXES.			MODES OF APPLYING HEAT.		
A.—Borax.			a.—Naked fire.		
B.—Sal-ammoniac, or mur. of ammonia.			b.—Hollow furnace or muffle.		
C.—Muriate, or chloride of zinc.			c.—Immersion in melted solder.		
D.—Common resin.			d.—Heated solder or metal poured on.		
E.—Venice turpentine.			e.—Heated iron not tinned.		
F.—Tallow.			f.—Heated copper tool, tinned.		
G.—Gallipoll oil.			g.—Blow-pipe flame.		
			h.—Flame alone, generally alcohol.		
			i.—Stream of heated air.

The application of this table is now shown:—Iron, cast-iron, and steel, 8, B, D, if thick heated, by a, b, or c, and sometimes by g. Tinned iron, 8, C, D, f. Silver and gold soldered with pure tin or with 8, E, a, g, or h. Copper and brass, gilding metal, gun metal, &c., 8, B, C, D; when thick, heated by a, b, c, e, or g, and when thin by f or g. Speculum metal, 8, B, C, D; the heat to be cautiously applied—sand-bath for preference. Zinc, 8, C, f. Lead and lead pipes, 8, D, and G, mixed, g, also f. Britannia metal, 8, C, D, g. Pewters, the solders vary in fusibility according to that of the metal; generally G, and i, are used, sometimes also G and g, or f. The whole of the table of Mr. De Claubry, which enumerates 102 different alloys, &c., may be found, we believe, in "Le Dictionnaire de l'Industrie Manufacturière Commerciale, et Agricole, par A. Baudimont" (Paris ed. 1833), Vol. I., 326. We may further add here, that iron and brass, &c., are sometimes burned or united together by partial fusion, by pouring very hot metal over or around them (d). Lead is united without solder by pouring on red-hot lead, and employing a red-hot iron (d, e), and also by the autogenous process to be hereafter described.

Soft-soldered joints should be well cleaned, and it is usual with all the metals, except clean tinned plate, or tin alloys to scrape the edges where the solder is wanted to adhere. Lead works are first

meared round the intended joint with a mixture of lampblack and size, to prevent the adhesion of the intended solder; then the parts to receive the solder are scraped quite clean and the clean part rubbed over with tallow. Some joints are wiped without using the soldering iron; A, i, e, the solder, is heated just below melting point, poured on the joint to heat it; the solder is then smoothed with the well greased piece of bed-tick, with which the surplusage of solder is removed. Other lead joints are left in ridges from the bulbous end of the iron, which is heated nearly to redness, and not tinned; the iron and cloth are both used at the commencement, for moulding the solder and heating the joint. Vertical joints, and those for pipes, require the cloth to support the fluid solder when poured on the lead.

Slight works in lead requiring more neatness than ordinary plumbing are soldered with the copper bolt represented in Figs. 2 and 4. These bolts are pieces of copper rivetted into iron shanks, and fitted with wooden handles. All works in tinned iron, and sheet zinc, and many in copper and other metals, where thin, are soldered with this tool. To tin this bolt heat it to a dull red, hastily file it to a clean surface, then rub it quickly, first on a lump of sal-ammoniac, and then on a bit of tin solder. In soldering coarse work, when the edges are brought together, slightly strew on resin, contained in the box, Fig. 3—the copper bit is held in the right hand, the cake or strip of solder in the left, and a few drops are melted along the joint at short intervals. The bolt is then used to heat the edges of the metal, and to fuse and run the solder. The tool must not be too hot, else it will not pick up drops of the solder from the cake on the tray, Fig. 1, to distribute it along the edge. The tool is sometimes passed only once slowly along the work, but the operator is in this case dexterous, uses a tool with a thin keen edge, and the flux used is muriate of zinc, with which the joint is moistened with a bit of wood, previous to the application of the tool. One section of the tray is devoted to a wet rag, on which to cool an overheated tool.

Copper works are commonly fluxed with powdered sal-ammoniac, and so is sheet-iron; but various methods are adopted by various people, but any mode will suffice so long as the metals are de-

fused from oxidation. Zinc is more difficult to solder than other metals. The flux sometimes used is sal-ammoniac, but the muriate of zinc (made by dissolving fragments of zinc in muriatic acid, diluted with an equal quantity of water) is superior, and serves well for all the other metals, without strict necessity for clean surfaces.

We are here reminded by a correspondent that in soldering small articles a difficulty is experienced in using the common copper bit or blow-pipe, from the heat given forth passing to the parts of the work surrounding that to be soldered. The tool at Fig. 5, with the bolts *c, c, c*, inserted at *c* in the holder will obviate this difficulty. In using it, heat the iron red-hot, slip in the bolt—in a minute it is hot enough to do its work.

Space compels us to leave the description of Fig. 6, the pewterer's hot air blast, until our next.

(To be continued.)

THE ROYAL OBSERVATORY AT GREENWICH.*

(Continued from page 138.)

The interior of the tube, its glasses and wires, being now all right, or the amount of error known, the outside requires attention, for should the pivots on which it turns be out of level, the telescope will be tilted on one side, and not point to the meridian, consequently, the unfortunate astronomer will see the star cross the micrometer wire before or after it is on the meridian, and he will register the real time of transit incorrectly. Thus it is necessary to test even the polished iron axis and its bearings, and this "error of level" is ascertained, not by a spirit level, but by the following very ingenious and simpler contrivance. The transit circle telescope is turned completely upside down, till it points to a trough of mercury beneath. A ray of light from a gas jet is then thrown from a glass plate *E* on all the micrometer wires, which are thus brilliantly illuminated. Should the horizontal axis of the telescope be perfectly level, the observer will see only one set of wires, because the reflected images from the mercury will be thrown back upon, and exactly coincide with the real wires. Should the pivot be out of level, the real and reflected wires will not coincide, consequently the observer at *E* will see two sets of wires, one set rather more brilliant than the other. In the cut the central micrometer wire *C* illustrates the principle. Should the pivot not be out of level, one wire only will be seen at *C*. Should it be out of level, for instance, at *B*, the dotted lines show how the image will be reflected by the mercury to *D*, whereby the astronomer will see two wires *B, D*, instead of one. By moving the micrometer wire the two sets of wires are made to coincide, the mean of the micrometer readings is taken, and the difference between the mean reading and the reading corresponding to the line of collimation, is the error of level.

But the cares of the astronomer are not yet over. If the Connecticut witches, who, as everybody knows, once swept the cobwebs out of the sky, had only left one thread in the true meridian of Greenwich they would have saved a deal of trouble. The true central line of the telescope has now been ascertained, as well as the level of the pivots, consequently, the tube will do to take an observation of a star crossing the zenith. Should, however, one of the pivots be too far north or south, on turning the telescope over towards the horizon, every inch of that motion will make it point more and more away from the meridian. This is known as the "azimuthal error," and is not very difficult to ascertain. Should the tube first point to the zenith, and the axis rest truly east and west, on the turning the telescope over it must at last come plump upon the North Star, the whole of its motion being in the true meridian. As a matter of fact the mechanical portions of the apparatus are so well made, that on swinging the telescope over the North Star does always come into view, but the North Star has an apparent orbit the centre of which is the true north, and not the star itself.

The azimuthal error, then, is determined by observations of Polaris, or of β Ursæ Minoris, at consecutive passages above and below the North Pole.

Other stars also can be employed, sometimes, for instance, the stars Cephei 51 (Hev.) and λ Ursæ Minoris. However, the North Star may be chosen to illustrate the method of detecting the amount of azimuthal error. Let *A, E, F, H*, be the small circle described by the Polaris the North Star, round *G*, the true pole of the heavens, the line *E, G, D*, being the true meridian of Greenwich, and *C* the zenith. Should the eastern pivot of the transit circle telescope be too far north, a line *A, B*, through its centre, instead of coinciding with the true meridian, will cut the circle at *A* and *H*. As Polaris takes twenty-four hours to complete the circle, if the telescope pointed to the true north, the star would cross its field at *K*, and exactly twelve hours afterwards at *E*. If, however, as in the cut, it did not point to the north, the star would cross it at *H*, apparently behind time, and again at *A*, apparently before time, the whole interval being considerably less than twelve hours. This period of time gives the data from which the azimuthal error is computed. The azimuthal error tables commonly used at Greenwich are for the most part based upon observations of Polaris above and below the pole. The angle of error is computed from the zenith, at *C*.

The cast iron graduated vertical circle of the transit instrument, for "zenith distance" observations, is 6ft. in diameter, with two sets of divisions. The set on the western side is cut upon a band of silver let into the iron, and divided into five minute spaces, which have to be read by microscopes; the other side is divided by points to every five seconds. There are six reading microscopes, which are simple perforations through the stone pier, having their object glasses inside, next to the graduated circle, and their eye-pieces outside, in a circle about 21in. in diameter.

Such are the leading features of the great transit circle at Greenwich Observatory. After all the care that is necessarily taken to learn the amount of the sources of error, it does not follow that when an observation is made that the telescope itself points to the true meridional line. Its deviations from that line are however known by the above tests, and the error allowed for by calculation rather than by adjustment of the instrument. The error of collimation is much under control, and kept very small by adjustment, the remainder being allowed for in the calculations.

The altazimuth instrument, as represented above, was erected in 1847, specially for lunar observations, Mr. Simms being the optician, and Messrs. Ransomes and May the engineers. Like the great transit circle, it has a very firm foundation, consisting of a three-rayed pier of brickwork, built up from the solid ground, and having no connection with the building. The radial arms of the iron triangle, supporting the upper part of the instrument, rest upon a smaller pier on the centre of the brick pillar. All parts of the frame possess great firmness, the principle of construction adopted, being to make as much of the instrument as possible in single solid casts of metal, to avoid the use of small screws, and to give the observer no power of adjustment. All errors are calculated by the methods already described, and allowed for when reducing the observations. The altazimuth instrument, like the great transit circle, has a room to itself, with the usual mechanical appliances, for opening and closing the shutters in the sides and roof.

The Astronomer Royal thus describes the instrument:—"For the support of the upper pivot a horizontal iron triangle is carried by the three-rayed pier; on each side of this there is mounted a vertical iron triangle; and the three vertices of these are connected by an upper horizontal iron triangle; three radial iron bars, supported on its angles, carry, at their point of union, the Y in which the upper

pivot of the vertical axis turns. The frame revolving in azimuth consists of a top and bottom, connected by two vertical cheeks, all of cast iron; the microscopes for viewing the divisions of the horizontal circle are cast in the same flow of metal with the bottom piece, and those for viewing the divisions of the vertical circle are cast in the same flow with one of the vertical cheeks. The vertical circle and telescope are of gun-metal; the side of the circle which carries the graduated limb, the ends of the telescope, and one of the pivots, being cast in one flow; and the other side of the circle and its pivot cast in another flow. The diameters of both circles (horizontal and vertical) are 3ft.; the length of the telescope is 5ft.; the aperture of its object glass 3 $\frac{1}{2}$ in. The top carries two levels and the bottom carries two levels, parallel to the axis of the vertical circle; the vertical cheek which carries the microscopes carries also two levels parallel to the plane of the vertical circle."

(To be continued.)

VELOCIMETER.

A simple piece of mechanism, which shall at once tell the distance to which the vehicle it is attached has run, and the consequent speed per hour, is a something which has yet to be manufactured. It has often been attempted—we are not aware that it has been achieved, so as to be readily applicable to cab or hansom, or locomotive engine. Such an index in a railway carriage would be a great convenience to passengers, and its presence there would operate as a mental check on a driver tempted, through slacking pace here and there, to make up for loss time by racing his train. The annexed sketch, which has been forwarded to us by a correspondent named "R. J. Atcherley," is an offer in this direction; but, whilst saying that it will not do, for reasons which are self-evident, yet we give it publicity for the purpose of drawing forth the inventive talent of some one or more of our readers.

A, A, are levelled wheels, applied to change the direction of rotary motion; B is a hollow rod containing a smaller rod F, which is fastened in a loose socket to the sliding clasp D, and which, when the wheel at G is in motion, and the iron balls G, G, rise with the increasing speed, will mark on a graduated index at E, the rate of the speed per hour in miles at which the said wheel is moving.

ALLOY.—"Fusible metal" consists of two parts by weight of bismuth, one of lead, and one of tin. It received its name from being at the time of its discovery, and long after, the most fusible metallic compound known. It melts at about 200 deg. Fahr. It has been found, however, that the addition of cadmium renders the point of fusion still lower. Thus, one equivalent of cadmium and one of bismuth, one of lead and one of tin, or two of bismuth, two of lead, and two of tin fuses at about 155 deg. Fahr. Three equivalents of cadmium, four of bismuth, four of lead, and four of tin fuses at about 153 deg. Fahr. And four equivalents of cadmium, five of bismuth, five of lead, and five of tin fuses at 150 deg. Fahr.

(* Extracted from the Engineer.)

KRUPP'S STEEL TIRES

Mr. Thomas Prosser, Krupp's agent in America, has issued a pamphlet from which we extract the following:—"Mr. Winslow (master mechanic of the Housatonic Railway) states that the Reindeer, weighing 45,054 lb., ran 72,483 miles, with an average wear by abrasion of 3-16in., on a set of four of Krupp's cast steel tires. These wheel tires, which were 57-75in. diameter when they commenced running, where 57-375in. diameter when they had run these 72,483 miles; the average width of the wear of each tire was 2½, which gives 87 lb.=149 lb. per thousand miles for a 25-ton engine, as the amount of wear by abrasion only. The wear by abrasion of the puddled steel tires on the Luxemburg, we have seen, was 4 117 times as much as Krupp's cast steel ones, and we are quite certain that iron ones wear much more. Hence we assign 358lb. for loss of metal by mere abrasion of puddled steel tires in running 60,000 miles =614 lb. per 1,000 miles with a 25 ton four-wheel locomotive, while a former statement makes the loss of iron tires 7-217 lb for the same service.

IMPROVEMENTS IN STEAM ENGINES.

Mr. Geo. Yellott, of Baltimore, has invented an engine, in which the cylinder is constructed in two sections, of unequal diameter, each section being one-half of the whole length of the cylinder, with the end of the section of larger diameter open, and the end of the section of smaller diameter closed, with a piston fitted air-tight and steam-tight in each section, and the two pistons connected by a piston rod, so that when steam is admitted into the smaller section and acts against the piston in that section, the other piston in the larger section may be driven out against the resistance of the atmosphere, and the reactive pressure of the steam on the closed end of the smaller section of the said cylinder occasioned by said resistance may be used as the motive-power of the engine. He also claims as part of his invention the cylinder in combination with and placed horizontally on the platform supported at its outward edge by the wheel resting on the circular rail, and attached to and revolving with the vertical shaft, with the upper and lower extremities of said shaft working steam-tight in the two steam-tight boxes, and with the hollow spaces in the upper and lower portions of said shaft, for the admission of steam from the boiler and the escape of exhaust steam, the said cylinder being placed on said platform, with the closed end of the smaller section perpendicular to the centre of motion of said vertical shaft, and firmly attached to said platform, so that it may be made to revolve with it. He likewise claims other modifications in detail of the same arrangement.

MODELS IN THE SOUTH EASTERN INDUSTRIAL EXHIBITION.

Amongst the most remarkable objects in mechanics are Messrs. Penn and Co.'s superb model of the engines of the Minotaur and the Northumberland, of 1,350-horse power, the model being made to the scale of one inch to the foot. For compactness of arrangement, completeness, and effective working, we venture to think that these engines are as yet unsurpassed by any others hitherto constructed. Immediately adjoining Messrs. Penn's model is another, almost equally beautiful, contributed by Mr. John Matthews (of the same firm), showing the parts, in all their details, of a direct-acting marine engine, fitted with an ordinary paddle-wheel on the one side, and with feathering blades on the other. Adjacent to these is a model somewhat rougher in finish, yet tolerably slightly, of a cigar boat for sailing. The cigar boat that is being built on the other side of the river, and which has excited considerable interest in the district, has attracted the attention apparently of Mr. W. H. Child, a journeyman shipwright, who has made a model considerably different from the vessel being constructed at Blackwall, in this especially, that Mr. Child puts a deep—very deep—keel to his vessel. It is professedly adapted for sailing, and not steaming, and as yet on the Serpentine, and in any other contests in which it has had the chance of engaging, this model has beaten hollow all the miniature clippers that have been tried against it. The body of the boat is of zinc, the keel of lead. It is about 3½ft long.

In the time of Henry VIII. the Royal Navy consisted of one ship of 1,500 tons, two of 800 tons, three of 600 tons, and six or seven smaller. At his death the navy was extended to fifty ships, making 12,000 tons, manned by 8,000 men. Elizabeth's fleet in 1588 consisted of one hundred and seventy-six ships, with 15,000 men. At the death of George II. there were four hundred and twelve ships, measuring together 321,000 tons.

PATENT LIST.

(From the Commissioners of Patents' Journal.)

LIST OF SPECIFICATIONS, &c. PUBLISHED DURING THE

WEEK ENDING 9TH DECEMBER, 1865.

194. Apparatus for dispersing scents, E. Atkinson—6d.
 195. Window blind cord check, E. Templemore—4d.
 196. Preventing noise from furniture, A. Drevelle—4d.
 197. Floorcloths, J. B. Wood—4d.
 198. Drying paper, A. Sheldon—4d.
 199. Folding chairs and seats, T. Brown—10d.
 200. Reaping and mowing machinery, W. E. Newton—10d.
 201. Petroleum and coal oil burner, M. A. Dietz—8d.
 202. Manure, B. King—4d.
 203. Viceroy, C. T. Wells—8d.
 204. Grinding and dressing flour, R. R. Riches and C. J. Watts—10d.
 205. Electric pile, J. Rovero and H. A. B. Huguet—4d.
 207. Preserving fruit and alimentary substances, G. Haseltine—8d.
 208. Fly presses, J. Bailey—4d.
 209. Woodward, and A. Woodward jun.—1s. 10d.
 210. Lowering and disengaging boats, T. Steel—8d.
 211. Grinding grain and other substances, A. Stevenson—4d.
 213. Gun barrels and ordnance, J. Marshall and H. Mills—4d.
 214. Hair-brushing machinery, C. Boyne—8d.
 215. Carriages, S. L. Fuller, A. Fuller, and C. Martin—10d.
 216. Adjusting the weight of railway carriages and engines, O. Gosnell—8d.
 217. Packing, W. Paton—4d.
 218. Photo-sculpture, D. Gay—4d.
 219. Preventing deposits in steam boilers, C. D. Abel—4d.
 220. Compressing coal dust and materials for brick-making, &c., W. Smith—4d.
 221. Manufacturing sugar from maize, &c., G. Haseltine—4d.
 222. Optical illusory apparatus, J. H. Pepper and T. W. Tobin—8d.
 223. Valve or tap, B. Sharp—4d.
 224. Lining puddling and other furnaces, B. Mushett—4d.
 225. Cleaning ships' bottoms, J. Harrison—10d.
 226. Purifying coal gas, A. A. Croll—4d.
 227. Colouring wool and hair, H. W. Ripley—4d.
 228. Propelling vessels, J. Hamilton jun.—1s. 10d.
 229. Manufacture of iron and steel, J. G. Williams—4d.
 230. Ice safes, C. Falck—8d.
 231. Beating and dressing flax, W. Cressy—2s. 3d.
 232. Preparing and fixing metal roofing plates, G. Dibley—8d.
 233. Ships' logs, J. E. Massey—8d.
 234. Penicill cases, W. Clark—4d.
 235. Compass for ascertaining the area of circles, J. E. F. Ludeke—6d.
 236. Throat spinning frames, C. D. Abel—10d.
 237. Pumps, J. Hind—10d.
 238. Removing dirt from the barrels of keys, R. Hesham—4d.
 239. Saddle-trees, J. Southall the younger and H. Southall—6d.
 240. Farnes, C. De Buge—4d.
 241. Obtaining variable speed in machine tools, J. Combe—1s. 4d.
 242. Working windlasses and other ships' gear, H. Moor—4d.
- * Specifications will be forwarded from the Commissioners of Patents' Office, Southampton-buildings, Chancery-lane, by post on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post-office Order, made payable at the Post-office, 5, High Holborn, or Mr. Bennett Woolcroft, her Majesty's Patent Office. We cannot undertake to forward Specifications, or Books advertised from the office of THE ENGLISH MECHANIC.

Now Publishing,

PRICE TWOPENCE,

"EXCELSIOR," "EXCELSIOR"

Family Sewing & Embroidering Machine

WITH ALL THE LATEST IMPROVEMENTS.

IS easy to operate, simple to learn, quiet in action, and not liable to derangement. It will TUCK, HEM, FELL, GATHER, CORD, QUILT, BRAID, and sew from two ordinary reels, requires no re-winding, and the seam, if cut at every inch, will not rip. Price from £6 6s.

WHIGHT AND MANN, 148, HOLBORN BARS, LONDON.
MANUFACTORY—GIFFING WORKS, IPSWICH.

PRICE LISTS FREE.

Crickmer's Patent Plastic Metallic Packing.

FURTHER REDUCTION IN PRICE ON AND AFTER OCTOBER FIRST.
PATENT WIRE GAUGE JOINT PACKING... 1s. 6d. per lb. INDIA-RUBBER CORE PACKING (HERM) ... 1s. 4d. per lb.
CRICKMER'S PATENT PACKING ... 1s. 3d. Do. (OUTTON) ... 2s. 6d. Do.
This Packing takes less Tallow to lubricate it than any other, and being a Filable Metallic Surface requiring but little Pressure to keep it Steam tight, there is a great saving in friction.
PATENT TALLOW PUMPS AND LUBRICATORS.
WELL STRETCHED LEATHER MILL BANDS. HOSE PIPES. FIRE BOCKERS. VALVES. WASHERS, &c., &c.
CAUTION.—Engineers, Millwrights, and others are cautioned against Purchasing a Spurious Metallic Packing, purporting to be Crickmer's. THE ABOVE CAN ONLY BE OBTAINED FROM

ALEX. ROSS AND CO.,

GRANGE ROAD, BIRMINGHAM, the only Authorized Agents. Price Lists on Application.

No FITTER or TURNER should be without a Straight-edge.
The most reliable tool of this kind, graduated to the Standard Measure of the Realm, and manufactured with MARVELLOUS ACCURACY, may be obtained of

RICHARD LLOYD.

MILL AND MACHINE IRONMONGER.

135, STEELHOUSE LANE, BIRMINGHAM.

Clubs of Workmen supplied at reduced prices. No equal tool is sold under FOUR TIMES THE PRICE.

CHANGE WHEELS FOR SCREW-CUTTING LATHES.

J. H. McMOBBAM.
ENGINEER AND MODELLER,
140, SALISBURY COURT, FLEET STREET.
Castings supplied.

NATIONAL BOILER INSURANCE COMPANY (LIMITED),

27, LEADENHALL-STREET, LONDON.

JOHN SMITH & Co.,
ENGINEERS AND BOILER MAKERS,
Sole Lenders: Agents.
All Boilers supplied by this firm insured the Twelve Months Free of Charge.

W. & A. CLOVER,
ENGINEERS, MACHINISTS,
LATHES AND TOOL MAKERS,
191, OLD KENT ROAD.
SMALL SCREW CUTTING, TURNING, AND PLANING.

JOSEPH STANLEY,
(Late Foreman at David Hart's.)
ENGINEER AND BUILDERS' PATTERN MAKER.
33, FIELDGATE-STREET, WHITECHAPEL-ROAD, E.
Patterns designed and arranged from instruction according to requirement.

JAMES LEWIS,
(Late Lewis & Son).
ENGINEER, MACHINIST, LATHE & TOOL MAKER, and Modeller of New Inventions.
41, GREAT QUEEN-STREET, LINCOLN'S INN-FIELDS.
(Late of 5, Wynd-street, Strand.)
Machinery made to Drawings or Patterns, and Worked out to Scale.

C. SUFFELL, MATHEMATICAL INSTRUMENT MAKER, 11, BRIDGE-STREET, WESTMINSTER, begs to call attention to his Improved Levels and Theodolites as manufactured for Her Majesty's Government. The pocket sets of Instruments, from 16s. to 43s.; Telescopes, 6 miles range, from 6s. 6d.; 10 miles ditto, 8s. 6d. and 10s. 6d.; Boxwood scales, engine divided, 2s. 6d.; Telescopes, 1s. to 6s.; Measures and Rules of all nations. Post-office orders payable at Charing Cross branch. Lists of prices forwarded on application.

TRADE MARK.

J. H. TUCK AND CO.
begs to call attention to the annexed "TRADE MARK," which is future will appear upon each length of TUCK'S PATENT PACKING, as also upon their other Rubber Manufactures.

Valves guaranteed quality, Sheet India-rubber, Hose, Tubing, Banding, Buffers, &c., &c.

J. H. TUCK AND CO.,
35, CANNON STREET, E.C.
WORKS, LAMBETH.

TUCK'S PATENT STEAM PACKING.

FOR STEAM-ENGINES, PUMPS, &c.

ADVANTAGES.—A more perfect vacuum is obtained. Friction reduced. Great saving in oil and tallow, and the packing is gradually and completely worn away without becoming hard.

THUS OBVIATING THE NECESSITY OF DRAWING THE OLD PACKING.

Consulting Engineers and Patent Agents,
in connection with

WILLIAM SMITH, Esq., C.E., Director of the Artisan Patent Office, London, Proprietor and Editor of the "Artisan," a Monthly Record of Engineering and the Industrial Arts, TRANSMIT ALL BUSINESS RELATIVE TO PATENTS AND FOREIGN PATENTS FOR INVENTIONS, AND THE REGISTRATION OF DESIGNS, AND EXHIBITS PLANS AND SPECIFICATIONS OF ALL KINDS OF MACHINERY IN THE MOST CORRECT MANNER, AT THE LOWEST POSSIBLE CHARGES. Provisional Protection, 25s. Ordinary Charges for Complete Patent, £40.
All general information in reference to Patents given free on personal application, or by letter, when an addressed stamped envelope is enclosed.
The "Artisan" supplied, and all business for it in Scotland may be transacted at the above Office, 30, Buchanan-street, Glasgow.

HOLLOWAY'S PILLS. THE READY REMEDY. When winter sets in the human constitution undergoes many trials, from some of which disease will spring, unless the blood expelled from the surface of the body finds organs capable of blood expelled from the surface of the body finds organs capable of receiving it, and secretion adapted to consume it. This preservative power is admirably displayed by proper doses of Holloway's Pills which relieve the liver, kidneys, and bowels, from undue congestion by immediately augmenting their secretions, and so diverting any surplus quantity of blood from a situation where its continued presence must be mischievous. With these Pills and an attentive pursuit of their advice is required to conduct even the delicate through the trying time of winter.

PATENT HOLLOW STEAM PACKING.

THE great and peculiar advantages of this packing consist in its remaining perfectly elastic, and is so constructed and applied that the pressure of the steam itself makes the joint by entering the packing from the cylinder; thus the many objections to packing previously existing are effectually removed. Vulcanised India-rubber Sheet, Washers, Valves, Springs, Hose, Glazed and Solid Tubing for Gas, Speaking Tubes, Diving Dresses, Gas Bags, Air-proof Goods, or any description of India-rubber articles made to order.

Price list or circular, with full description of packing, to be had of the only Manufacturers and Patentees of Hollow Steam Packing.

FOSTER and WILLIAMS, India-rubber Works, Cowper-street, City-road.

THE IMPROVED LEATHER DRIVING

STRAPS FOR MACHINERY are stronger for a given weight, more effective, more durable, and cost considerably less than any other kind of Driving Belt. Special Straps for Portable Engines. Price Lists free.

Turner's Patent Strap and Hose Company.

Manufactory, Armit Works, Greenfield, Manchester. Warehouse, 81, Mark-lane, London, E.C. Mr. H. FERRABEE, Agent.

ROSCOE'S SELF-ACTING LUBRICATORS FOR STEAM ENGINES.

Testimonials and Prices Post free.

Apply to **EDWIN H. NEWBY,**

31, CHEAPSIDE, and LEICESTER.

The above Lubricators grease every particle of steam previous to its passing through the valves into the cylinders.

INVENTIONS PROTECTED BY

PATENT or REGISTRATION, at fixed and most moderate charges. The Inventors' Manual free by post, or gratis on application.—Apply to Mr. BREWER (late Barlow and Co.), 89, Chancery-lane, London, W.C. Established 21 years.

INVENTORS ASSISTED

IN Securing, Carrying Out, and Disposing of their Inventions.—Apply to Messrs. B. BROWNE and CO., British and Foreign Patent Office, 49, King William-street, London-origins.

A Pamphlet gratis, on Cost of Patents, may be had on application.

INVENTIONS secured by Patent or Regis-

tration, on moderate terms, by application to Mr. WILLIAM BROOKES (of upwards of 25 years' experience in such matters). British and Foreign Patent Agency, 69, Chancery-lane, London, W.C.

TO INVENTORS.—GENERAL

PATENT OFFICES.—L. de FONTAINEMOREAU, 4, South-street, Finsbury, London; 19, Rue de la Fidélité, Paris; 33, Rue des Minimes, Brussels. Provisional protection, 27; to complete patent, £30; French patent, £26 10s.; Belgium, £2 10s. Circular gratis on application.

PATENTS FOR INVENTIONS.—Full

instructions may be obtained by applying to Mr. W. T. RAWLE, Office of British and Foreign Patents, 8, Small street, Bristol.

NOTICE TO INVENTORS.—Office for

Patents, 4, Trafalgar-square, Charing-cross. Printed instructions (gratis) as to the Cost of PATENTS, for Great Britain or foreign countries. Advice and assistance in disposing of or working inventions. Branch offices and agencies in every Continental State and in America. Established 30 years. Full information as to expired or existing Patents at home or abroad. Apply personally or by letter to Messrs. PRINCE and Co., Patent Office, 4, TRAFALGAR-SQUARE, CHARING-CROSS, W.C.

WHEEL, RACK, and SCREW CUTTING.

SPUR, BEVEL, RATCHET, WORM and INTERNAL WHEELS cut to any size or number of teeth; also racks of any length or pitch. Dividing plates drilled or lined. Screws cut to any size or pitch. J. Wilkinson, Engineer, St. George's Works, 83, St. George's-road, S. London.

A MARVEL OF CHEAPNESS.—THE

newly Invented POCKET TIMEPIECE, with handsome gilt case, and an elegant enamelled DIAL, interspersed with gold, price by post 14 stamps.—JOB MALPASS, Kidderminster.

THE LONDON DRAWING ASSOCIATION

for supplying Engineering, Mechanical, Architectural, and General Drawing, Designs, Maps, Plans, Tracings, Wood Engraving, Electrotyping, 7, Duke-street, Adelphi, London. Enclose stamp for prospectus.

SECOND-HAND CASES OF MATHEMATICAL INSTRUMENTS.

Theodolites, Levels, Pentagraphs, Quadrants, Sextants, Universal Dividers, Circumferencers, Prismatic and Beam Compasses, Ivory and Boxwood Scales, Land Chains, &c., by Troughton and Simms, Elliott, Dolland, and others, at WM. LAWLEY'S, 78, Farringdon-street, City. Photographic Cameras, Lenses, Magic Lanterns, Slides, Dissolving View Apparatus, Microscopes, Telescopes, Opera, Race, and Tourist's Glasses, by Voigtlander, Ross, Dallmeyer, and others. Instruments bought or exchanged. Catalogues forwarded on receipt of three stamps for each.

SCREW CUTTER'S GUIDE,

Price 1s. 6d., or stamps.

Containing 115 Pages and nearly 2,000 Tables of Wheels, all different threads and pitches.

Tables for Tap making for Engineers, 1 to 6 inches, Gas Taps 1/2 in. to 2 inches, Mr. Whitworth's thread and make.

A Lithograph showing a new radius gear invented by the author of this work.

May be had at James Martin, 19, Wilson-street, New Cross-road, Deptford, Kent.

Self-acting, Turning, and Screw-Cutting Lathes,

FIG. 3.

COAL-GETTING MACHINERY.

If there is any one thing more than another through which we may lay claim for consistency during the existence of our journal, it is that of doing what we could to popularise the subject of coal-getting by machinery, and thus to alleviate the sufferings of the

"black diamond getters" in their toils underground. Nor do we know of any one among the many who have entered this field as inventors who have shown greater perseverance and better deserved success than does James Grafton Jones, of the Blairston Ironworks, near Newport, in Monmouthshire. This gentleman has just come forth with a fresh patent for "Im-

provements in Machinery used for condensing atmospheric air, and in Machinery worked by compressed air, employed in getting coal, stone, and minerals," which we have this week partially illustrated, and are now about to fully describe.

For the purpose of condensing atmospheric air, the piston-rod of a reciprocating steam-cylinder is con-

needed to and works the piston of the air pump, the length of stroke of each piston being the same. The two cylinders (steam and air pump) are both fixed on the same bedplate, by which they are readily retained true to each other, the two end covers of the two cylinders where the stuffing-boxes are constructed, and through which the piston rod works areas close as may be together, simply allowing room to get at the two stuffing-boxes. The piston-rod does not pass through either of the covers at the other end of the two cylinders. The air-pump cylinder is contained in a trough or vessel, so that such cylinder may be constantly surrounded by cold water continuously supplied to the trough. The relative diameters of the two cylinders will depend on the pressure of the steam used in the steam cylinder and the pressure to which the air is desired to be compressed. The use of a fly-wheel and shaft are dispensed with, and the change of motion of the piston in the steam cylinder is obtained by tappets or spindles which pass through stuffing-boxes formed in the two end covers of the steam cylinder; the tappet at each end of the steam cylinder is at its outer end pin-jointed to the shorter end of a lever, which by its other end, by means of a connecting rod, gives motion to a slide valve. By this arrangement, as the piston arrives nearly to the end of its stroke it pushes out the spindle or tappet at the end of the cylinder, and the position of the slide-valve is quickly reversed. At each end of the air-pump cylinder are valve-boxes, in each of which is an induction and an eduction valve, which it is preferred should be circular, spindle-valves resting by their outer edges on rings of soft elastic matter as valve seats. A starting and stopping hand lever is applied to one of the axes of the levers which work the slide valve of the steam cylinder. The outlets of the two valve-boxes of the air-pump cylinder are connected together by a pipe, to which is connected the supply pipe to the engines or machines worked by compressed air. When the engines or machines are necessarily distant from the air-pump, two or more air vessels are employed in connection on the supply main, and for this purpose cylinders or other forms of vessels are introduced at intervals along the supply-main or pipe of such dimensions as may be desired, and depending on the size and speed of working of the compressed-air engine which is actuating the picks used in getting coal, &c.; by these means the supply of compressed air to the engine may be more advantageously made than when a long length of supply pipe or main intervenes between the pumping machinery and the compressed air engine without such enlargements or reservoirs. Heretofore the machines or engines worked by compressed air or other fluid used for actuating lever picks when getting coal have been arranged to be moved along the face of the work, and to cause the cutting points or edges of the lever picks to strike against the outer surface and move inwards to the depth desired. Mr. Jones now arranges these machines in such a way that the edges of the lever picks used begin to act on the back of the material and move outwards, so that when the pick has completed a cut it shall be out of the working, and require to be moved back into the working before it makes its next cut; by this means lever picks will be less liable to be held in the workings than when the point or cutting edge penetrated more and more into the solid mass till it arrived at the end of its stroke. For this purpose the lever picks are held by the machinery, and are worked in a reversed position, and in commencing to work a chase or cut is first made by hand or otherwise to the depth desired for such a distance as will admit of receiving a lever pick into it, and at the same time allow of its cutting edge commencing at the back of the work, and to cut outwards, completing its cut at the outer surface of the work, that is, the cutting edge of the lever pick is caused to cut toward the engine which works it, in place of cutting in a direction from the engine, as has heretofore been the practice when working lever picks by like engines. Having selected the engine and air-pump for illustration, we will now proceed to describe them.

Fig. 1 is a side elevation, Fig. 2 a longitudinal section, and Fig. 3 a plan of an engine and air-pump constructed and combined according to the invention of Mr. Jones. *a*, *a* is the steam cylinder, having within it a piston *a*, the piston-rod *b*, of which gives motion to the piston *c*, in the air-pump cylinder *c*, *c*; these two pistons are shown to be of nearly the same diameter, but the relative diameters of the pistons of the steam cylinder and air-pump will be varied according to the requirements in each case. The air-pump cylinder is contained within the trough or cistern *d*, in order that it may be subjected to the action of cold water supplied to such trough or cistern. The air-pump cylinder has a valve-box *e*, *e*,

at each end connected together by a pipe *f*, *f*. In the arrangement shown the two tappets, *g*, *g*, are arranged to be one actuated by the steam cylinder piston *a*, whilst the other is arranged to be acted on by the air-pump piston *c*, which is the arrangement preferred; but if desired, both tappets *g*, *g*, may be arranged to be acted upon by the steam piston *a*, or both may be arranged to be acted on by the air-pump piston *c*. The tappets *g*, *g*, have a hand lever *g'*, by which the tappets may be moved when required, and such hand-lever *g'*, gives motion to the slide of a small steam engine *h*, by the rod *i*, which at one end is pin-jointed to the lever *g'*, and at its other end is pin-jointed to the cranked lever *s'*, which gives motion to the slide-valve of the small engine *h*. The hand-lever *g'* has also a stud on it which works in slotted links connected to the end of the spindle or stem *j*, of the slide valve *k*, of the steam cylinder *a*, *a*, by which, in the event of the valve of the small steam cylinder *h*, not acting correctly, the slide-valve *k*, of the engine *a*, *a*, will be moved by the hand-lever *g'*. The piston of the small steam cylinder *h* is on the spindle or stem of the slide-valve *k*, and there are stops *l*, *l*, on the other end of the valve spindle, which act against elastic packing in the standard *m*.

In carrying out the second part of the invention, air vessels are placed at intervals—says about every 80 to 100 feet, or at any other desired distances apart. These air vessels the inventor prefers to be of about the same length as the air pipe, which is usually about 4 inches in diameter and about 9 feet length, whilst the air vessels are about 12 inches diameter; but these projections may be varied. The object of this part of the invention is to have such a supply of condensed air near where the working of the picks is taking place that there may be a full supply of air to the condensed air engine or engines working the picks, so as to prevent as much as may be wiringdrawing of the air through the supply air mains between the workings and the air-pump.

In conclusion, we wish Mr. Jones every success possible, and that we may long have to congratulate him on his progress.

POWER REQUIRED TO DRIVE MACHINES.

One of our correspondents writes us:—I should like to get a table giving the number of horse-power required for the different sizes of circular saws, and we have no doubt that many persons who are about to start machinery would like to know what sized engines it is necessary to provide to drive their machines. For the benefit of these persons, we should like to collect a large number of facts in reference to the power employed in driving different kinds of machinery, and if any manufacturer, superintendent, or engineer, will send us a statement of the facts in his own case, we will, if approved, publish it, thus making our paper the medium for collecting and disseminating a great mass of knowledge in regard to this important matter.

Where an engine is employed we should like the diameter and stroke of the piston, the point of cut-off, and the average pressure carried; the dimensions of the boiler would also be interesting; then a statement of the machinery driven. Where machinery is driven by water power it would be of no interest to learn anything in relation to it unless enough can be known to enable the horse-power to be computed. This would require the height of the fall, and the quantity of water, either in pounds or cubic feet, passing through the buckets in a minute. Where this can be furnished, then a full description of the machinery in motion would be acceptable. We suggest that many manufacturers may find it to their interest to forward us a statement of these facts in relation to their establishments, while they will, at the same time, be disseminating very valuable information.

HUMROLDT has estimated the average annual amount of gold and silver which America furnished to Europe in the period from 1492 to 1500, at about £52,000 sterling; and the quantity of gold and silver produced from the whole of America since the discovery up to the year 1803 to be 162,000,000 lb. weight of the former, and 7,178,000,000 lb. of the latter.

The ancient Greeks used a mixture of salt, nitre, and alum when melting their gold, by which substance the silver was also purified. It is not improbable that lead was also added to promote the flux of the metals.

TO OUR READERS.

We have, at the very moment of going to press, received a letter from the solicitor of Messrs. Holtzapffel, the Engineers of Charing-cross, accusing us of pirating from their work on "Mechanical Manipulation." We need scarcely inform our readers that we were, up to the time of receiving the letter, in ignorance of such piracy. We consider Holtzapffel's work the leading authority for amateurs, and have often quoted it as such. Indeed, at page 148, in our last number, we inserted a letter from a correspondent, asking when the fourth volume of the work would appear. We have always endeavoured to inform our readers from whence we gather our information, that they themselves may search and read more fully, and, although as yet in ignorance as to the correctness or extent of the charge against us, we can but express our willingness to apologise if we have been led into error by any too eager contributor.

December 21, 1865.

A Christmas Present or New Year's Gift for the Apprentice or Improver!

Now Publishing THE FIRST VOLUME

of
THE ENGLISH MECHANIC,
A Record of Mechanical Invention, Scientific, and Industrial Progress.

UPWARDS OF ONE HUNDRED ILLUSTRATIONS.

Hundreds of Useful Recipes, and Thousands of Hints useful to Old and Young in all Trades and Professions.

Handsomely bound, only 4s. 6d.; post free, 5s.
OFFICE, 147, FLEET-STREET, LONDON, and all Bookellers.

TO ADVERTISERS.

As the ENGLISH MECHANIC addresses itself to the largest and most intelligent portion of the community, and is the only Paper of the kind established, it offers unusual advantages as an advertising medium.

OUR CHRISTMAS NUMBER.

In announcing his intention to publish an enlarged Edition of THE ENGLISH MECHANIC as a Christmas Number, To be issued on the First Tuesday in January, WITHOUT ANY INCREASE IN PRICE, the Proprietor respectfully submits that he thereby affords the many thousands of readers and numerous contributors an opportunity of each contributing a something as a Christmas and New Year's Treat for his fellows—some little "trick of trade" (in the good and true sense of the word); some improvement in tools, anything, in fact, which may be of value to brother workmen, and will assist in the promotion of feelings of kindness and good fellowship, which the season is so eminently calculated to call forth. The Editor will not fail on his part, and will be glad to find a hearty response to this challenge to do mutual good.

The English Mechanic.

FRIDAY, DECEMBER 29th, 1865.

YEAR'S END TO YEAR'S END.

WE do not know whether it is strictly "mechanical" the wishing of our readers, most heartily, a Merry Christmas and a Happy New Year; but we are willing to run the risk of being thought extremely unprofessional in this item, as we seek in it to cultivate that which is so much wanted all the world over—good feeling. During all the year now closing we believe artizans in general have met with remunerative employment; and the various tests—banks and societies which exist principally from and through the working masses, tell a very favourable tale. Our trades have not been "sewn up" by foreign competition; and the importation into this country of various kinds of fancy goods has now almost ceased, simply because their importers have found that they were doing something very much like carrying coals to Newcastle. For this we are indebted to Mr. Gladstone and free trade; for it was this set manufacturers to work in the improvement of machinery,

and the encouragement of talent in designing. True, for a while it seemed as if we were simply playing into the hands of the foreigner: we know better now, and are beginning to thank the great disciple of "goodwill to man," who could not be mentioned or complimented at a more fitting season than the present.

During the year past we have made the acquaintance personal and by letter, of nearly every one of our readers; and, we say it advisedly, we doubt if ever editor had a more intelligent class of correspondents address him. We trust we have been found equally valuable as acquaintances to all who weekly deposit their penny at our publishers' or agents,—it is not without our endeavouring hard to make ourselves so. Searching their own experience our reader will recognise the truth of the saying that it is a very hard task to please everybody—in fact it is an impossibility. But we are getting better acquainted with each other—Readers and Editor,—as we hope still better to be; and in this hope,—and looking back with thankfulness on the year passing away, and with hope to that now about to make its debut—we again cordially wish all our readers, gentle and simple, a hearty Christmas and a prosperous New Year!

BOILER EXPLOSIONS.

OUR attention has been called to one or two recent fatal boiler explosions, in the coroners' inquests over which, in the face of, to us, most convincing evidence to the contrary, verdicts of "Accidental Death" have been returned. It is almost needless to say that these boilers had been under the inspection of no association—in fact, we are told that neither of them had been inspected from the date of their erection—and one of them had been at work almost day and night for ten years! Where, we ask, in answer to our correspondents, is the use of our devoting space to full records of such unfortunate facts. Papers many years of age have been at it ever since their commencement, and have given it up in despair; and the only hope we see for those who, unfortunately, have to work in proximity to such boilers, and such thick-headed employers as use such faulty constructions, is such a spread of knowledge among all classes as will lead to a more intelligent inquiry both by coroner and jury, and, consequently, the alteration of the verdicts to "Wilful Murder." We are perfectly well aware of the fact that there are certain districts in this free country where truthful evidence on such a subject dare not be given. There is a remedy which Government might apply, and that is the production half-yearly, to the clerk of the peace, of a certificate, signed by a qualified engineer-inspector, that such and such boilers had been inspected and found sound—a very heavy penalty being attached to working steam from a boiler which had no such certificate. The remedy is a very simple one—when one of the Royal Family, or a big duke, gets thus "accidentally" killed, we may look for some such law being passed. As things go, this seems the only chance. It is very sad—it is none the less true.

TRANSFER ENGRAVING.

WHILST the articles on hardening tools, &c., were passing through the press, almost as a matter of course, we had various inquiries respecting the Perkins' admirable process of transfer engraving, which we now proceed to answer by describing the process.

A soft steel plate was first engraved with the required subject, and then the plate was hardened. A decarbonised steel cylinder was next rolled over the hardened plate by powerful machinery until the engraved impression appeared in relief, the hollow lines of the original becoming ridges in the cylinder.

The roller was reconverted to the condition of ordinary steel and hardened, after which it served for returning the impression to any number of decarbonised plates, each of which becomes an exact counterpart of the original. In the event of an accident to the roller, the original plate still remained.

To decarbonise the plates, they are placed vertically in cast-iron boxes, at least $\frac{3}{4}$ inch thick, and surrounded on all sides by a layer of iron filings half-an-inch thick; the boxes are then placed in a furnace, and, after being heated, suffered to cool in the most gradual manner by shutting off all air, and covering the boxes with a 6 or 7-inch layer of cinders. The re-conversion was similarly accomplished, but with the charcoal from leather sifted fins; and on removal from the boxes at the

end of four or five hours, the plates are plunged vertically into cold water. Thin steel plates are annealed at a higher temperature, in earthenware boxes filled with oyster shells. Good practice is to anneal at one time four cast-iron boxes, each holding from three to six steel plates, surrounded on all sides with fine charcoal, mixed with an equal quantity of chalk, and driven in hard.

The reverberatory furnace employed has a circular cast-iron plate, or bed, on which the boxes are fastened by wedges, and as the plate revolves very slowly (by the engine), the plates are exposed in the most equal manner to the heat, and when the proper temperature is attained all the apertures are carefully closed, to extend the cooling over 48 hours. The surfaces are thus rendered exceedingly soft to the 1-32nd of an inch; the device is raised in the transfer press under a pressure of some tons; and the plates are hardened without any intentional application of the case-hardening process, as the simple steel is superior to that which has been "treated." The plates are used in the soft state.

In hardening engraved plates, rollers, dies, and similar works, it is of the greatest importance to preserve the surface unimpaired, and, as steel is very liable to oxidation at the red heat, if exposed to the air for even a few seconds, and which oxidised scale will often nearly remove, or, at any rate injure the engraving; it is of the utmost consequence to conduct the heating and cooling with the most complete exclusion of air.

Oldham's process, from which the plates issue having the beautiful tints of case-hardened gunlocks, is as follows:—The work to be hardened is enclosed in a wrought-iron box with a loose cover, and a false bottom, and with three ears projecting from its surface about midway; the steel is surrounded on all sides with carbon from leather, driven in hard, and the cover and bottom are carefully luted with moist clay. Thus prepared, the case is placed in the vertical position in a bridle placed across a great tub, which is then filled with water almost to touch the false bottom of the case. The latter is now heated in the furnace as quickly as will allow the uniform penetration of heat. When sufficiently hot it is removed to its place in the hardening tub, the cover of the iron box is removed, and the neck or gudgeon of the cylinder is grasped, beneath the surface of the carbon, with a pair of long tongs, upon which a coupler is placed and "fletted" down, as the sailors phrase it, to secure the grasp. It only remains for an operator to hold the tongs whilst a smart tap of a hammer is given on their extremity; this knocks out the false bottom of the case, and the cylinder and tongs are instantly immersed in the water; the tongs prevent the cylinder from capsizing and injuring its contents. It is believed by many that steel plates are reduced to their softest state by enclosure with lime and ox-gall.

SCIENTIFIC NOTES.

M. Schrotter has reported to the Academy of Science of Vienna that he has successfully employed the light produced by the combustion of magnesium in the exhibition of the phenomena termed fluorescence, due to the very large amount of chemical rays which it possesses, and which renders it efficacious in the operations of photography. He found, by experiment, that dry chloride of silver assumed a blue colour when exposed for a few seconds to the magnesium light; and that platino-cyanide of barium showed great sensitiveness. Several bodies which become phosphorescent after having been exposed to sunlight during eight or ten minutes acquired this property after exposure to the magnesium light for a few seconds only.

M. A. Bechamp, in the conclusion of a note on the physiological exhaustion and vitality of yeast, read at a recent meeting of the Academy of Sciences at Paris, states that the results of his experiments are contrary to the opinion of Mitscherlich, who thought that the globules of ferment, well washed with water are entirely deprived of their property of acting on cane-sugar. M. Bechamp asserts that this yeast still continues to act on cane-sugar, since it has not ceased to live; and that, when it is so exhausted, it is simply reduced to its cellule, and will yet form grape-sugar and alcohol from sugar-cane. "The property of creating fermentation," he says, "is not to be sought in the catalytic action of some chemical compound which it may contain; it dwells—and everything seems to prove it—in the properties of the living cell; it is a consequence of the act of the nutrition of this cell." These conclusions are contrary to the opinion of Liebig, who says:—"The insoluble body termed ferment does not provoke fermentation."

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents.]

FORGING FAN.

Sir,—I beg to hand you a sketch of a small forging fan that I have found exceedingly useful, and which costs but a trifle. It is well suited for an amateur turner, being quite powerful enough to forge an inch bar of steel, or to weld half-inch iron.

It consists of a wooden wheel two feet in diameter, the fan is of tin plate, also the tuyere, except the nozzle, which is $\frac{1}{4}$ inch iron. The cost is about 10s., without reckoning my time.

I want to know how to turn iron rods 1 foot long and 3-16th diameter?
T. T. PARKINSON.

THE EXCHANGE.

Sir,—I am glad to find by the editorial note in the present number that your contributors are sensible of the advantages of a medium of exchange in their various pursuits of what is superior or unique for something of equal estimation.

The practice has long existed among naturalists, who exchange their surplus specimens of insects, butterflies, &c., for others they do not possess, and thus enlarge and add to the value of their general collections, and the acquaintances which often spring from these courtesies increase the charm of the study. Why not the same results in mechanic and other sciences, by which associations will be formed with those of kindred taste, infusing fresh interest in the pursuit of knowledge. They inspire with the hope of success, and invigorate those powers which must be exerted to attain it. The spark which kindles a train of light is sometimes struck out, and amidst a multitude of a tempest some effort more happy than the rest elicits an important discovery.

These remarks apply, of course, only to amateurs, because professionals in any line will retain what they produce, if superior or unique, to enhance their own reputation and profit. I consider the idea is good in itself, and calculated also to add to your own interest, influence, and usefulness.
THOS. WILLIS.

SOLDERING AND TINNING.

Sir,—Your table of soldering materials and process is exceedingly good; but you will find that zinc will solder best with pure muriatic acid, a single drop causing the solder to take instantly.

There is another difficulty in soldering large articles which I suggest for the information of your readers, where the copper bit is not heavy enough to overcome the thickness of the metal about to be soldered, which may be overcome successfully by partially heating the articles over the forge, and then applying the copper bit. A mere warning is sometimes sufficient.

Will any of your correspondents inform me of the process and ingredients employed for the tinning of cast-iron saucepans and other cast-iron work?
NIMROD.

RAILWAY SIGNALLING.

Sir,—Having frequently read of railway accidents, such as one train coming into contact with another on the same line, and having read also of the schemes that have been proposed for the prevention of the same, and of their failure, I venture to propose a system of signalling, which would effectually prevent such calamities, unless through the negligence of the driver, or other attendants, or through the signals being out of order.

The enclosed drawing is the system of signalling I propose. The signals will be worked by electricity or other equivalent, and set in motion by inclined planes, and anti-friction rollers, from the engine or break van (break van preferred, so that no accident could occur if the carriages became uncoupled). For instance, the train upon leaving the station, and in passing the first signal post, would raise the signal to indicate danger; and in passing the second signal post, would do likewise; and in passing

the third would also raise the signal; but, at the same time, would depress or replace the signal of the first signal post; the fourth, that of the second (as shown in the drawing where the train has just passed the fourth post), and the fifth that of the third, and so on, so that there would always be at least the distance between two signal posts for the drivers to stop the trains, so that it is obvious that no accident could occur unless through the causes previously mentioned—the signals would, of course, be placed at suitable distances.

In the drawing, *a*, are the electric wires; *b* the inclined planes; *c*, the rails. No. 6 is an end view of the signal post, with signal turned for danger.

The other systems of signalling have, I believe, failed, because the second signal depressed the first, the third, the second, &c.

I thank you for publishing my design in your paper of the 15th inst., and I hope you will oblige me by inserting this, as it is obvious that no accident can occur unless through negligence; or, unless the signals were out of order.

CHRISTIE J. LITTLE.

The "Exchange."

VELOCIPÈDE

Sir—As you have been so kind and liberal in your proposition, I think it is the duty of all subscribers to give a push at the wheel. As far as I can assist I will; but, if ever I should pay London a visit, you will have no occasion to fear I shall set fire to the river. Now to the point, that is the velocipède. If I was to make one, I should not like to feel lame on one side, so I propose using a pair of face ratchets to form a clutch joint, one cast on the nave of each wheel, the others to work loose on and with the main square driving shaft held in place with a lever in a grove, and a tight spiral or elastic spring to keep them in place

when at work; but when required for wheels to work loose on shaft, the levers are pushed out, and held with a catch; a pair of ratchets will be required for each hand. Let it be remembered the wheels run on a round part of shaft, so that in turning to right the left wheel slips over a tooth or two, and the same on the other hand, and running in a straight line, both are driving wheels, and a steady run is obtained. I send you a sketch—if you think it worth the trouble and expense of insertion.

G. W. WALTON.

OUR SUBSCRIBERS' NOTES AND QUERIES.

Will your correspondents throw some light on the following:—

In Dempsey's "Tubular and Iron Girder Bridges" he gives the contents in the formula for calculating the transverse strength of beams:—

For cast-iron 2548 value of *S*.
Wrought iron 2450 do.

Formula $Sbd^2 = lw$.

S, as shown; *b* = breadth in inches; *d* = depth; *l* = length in feet; *w* = weight in pounds.

He also gives the tenacity of wrought-iron, 27 tons; cast-iron, 8. Resistance to compression, wrought iron, 54 tons; cast do 48 pounds.—ASPERENT.

ECCENTRIC CHUCK.—Will a correspondent say what form of work the eccentric chuck is adapted for, also if the ring is used same as for an oval chuck. Is it possible to turn an oval (say one or two feet in length) when it has to be supported at both ends, and the means with ordinary centre and oval chuck? It is round at one end, and oval at the other.—D. HALL.

PIERCING STEEL.—Can you or any of your readers tell me the best method for piercing cast-steel?—SAMUEL JELLEY.

METAL.—I wish to know if there is a metal for a plug which will resist the action of the acid which is in tallow, and which will also resist the heat of steam?—METAL PLUG.

VELOCIPÈDE.—Will some correspondent inform me the price of a double velocipède, first or second hand, and the best place to obtain it? Also, the prices of lenses for

astronomical telescopes of the powers 300 and 600?—GLADIATOR.

MAGNETISM.—Will some reader kindly inform me the simplest process by which the metal magnesium is obtained?—B. V. HARLEY.

Can any one tell me how to enamel wood, the grain to show the same as if French polished?—FORWARD.

GILDING.—Can any kind correspondent tell me how to gild wood, and how to make the bases of glass shades (wooden ones I mean) imitate ebony and marble? A good imitation I want, of course.—PARIAH.

CUTTING SCREWS.—I should like to ascertain if there is any machinery made for cutting external and internal screw in wood, and if so, the maker of such machinery?—X. Y. Z.

TRACING PAPER.—Can any reader oblige me with a good receipt for preparing tracing paper; also carbonic or black tracing paper?—J. H. RAYNES.

ELECTRO-MAGNETIC ENGINE.—Will Messrs. Tonks, Electra, Furze, or any other of your electric correspondents, tell me what arrangement of battery, and what form of magnet is most powerful, lasting, economical, and compact, for the purpose of working an electro-magnetic engine?—COBB PULLY.

MAGNETIC.—Will any correspondent kindly furnish me with the best method of magnetising a bar of hard steel six inches thick and two feet long? and also, how I can tell when the bar is fully saturated with magnetism? In the autumn I saw at Ostend two bar magnets about this size, but composed of steel plates screwed tightly together. They were suspended by ropes that passed through a hole in the centre, and some inches apart from each other. The power of these magnets was so great that it required more than the strength of one man to bring their similar poles into contact.—R. W. WILLIS.

MICROMETER.—Having finished a fine objective metal of about 18 inches aperture, and 10 feet focal distance, being desirous of mounting it as an equatorial, I should feel extremely obliged to any scientific gentleman who would give a working description of a double position micrometer; also, general outline of the equatorial stand of Mr. Lassells, or the heavy reflector in the Glasgow Observatory?—T. W. B.

REPLIES TO QUERIES.

MANDRIL BINDING.—In reply to A. Turner, I can give no explanation as to the cause of his mandril binding while he is at work, without it is, that his mandril is taper, and without a shoulder. Now I have made them in a great many forms, but find the following kind the best for work and wear:—

Of course the collar is made to fit up to the shoulder on mandril, if A. Turner's mandril is taper, with no shoulder, the sooner he gets a new one the better.—W. H. PEARCE, lathe and tool maker.

CHUCK.—A correspondent, some little time ago, asked for a chuck for turning brass rods. One or two kinds appeared in your excellent little journal, but as I think that mine is better than any you have published, I beg leave to submit it to your notice. Take a piece of mild steel, and turn it to fit the lathe spindle like an ordinary centre, and bore a taper hole up the centre for about an inch, taking care that the hole is less than the rod, when the taper drill is put in the hole should taper 1-18th to an inch in length; this will be found very handy for turning any small work that can be finished before taken out of the lathe, such as straight and taper pins for collars on shafts, &c., and the brass rods your correspondent mentions.—ALPHA.

P.S. I should be very much obliged to any of your numerous readers if they would kindly give the rule for finding the weight of blow given by steam hammer.

BRONZING.—In answer to Chang's enquiry at p. 124, No. 37, I think that he had much better take his coffee pot to some one in the trade, as there is little hope for his success in attempting to do it himself, but I will give him an idea of the way to set about it; the first thing wanted is a forge, without which he can do nothing; presuming he has one, he must take the pot all to pieces, wiping off all the solder with a wisp of tow, and taking care not to let any of the metal in the fire, (for in the trade no metal is allowed on the forge where bronzing is done), then twist a little tow on the end of a stick, and pickle with "spirits of salts" all those parts that are tinned, pickling the outside as well as the in, rinse in water, and scour outside with wisp of tow and sand, fine coke dust is best for the tinned parts, which must be brought quite clean, rinse clean, smear the outside with wet whitening, and then tin with bar tin, sal-ammoniac being the best agent, and if he wants the inside to look nice, it must be wiped out dry so that none of the tin is left to run, then pickle only the outside with diluted spirits of salts, rinse, and scour with clean sand till the surface is perfectly clean and bright, taking care to rub as much as possible in one direction (tinning may not seem necessary, but if not done the old tin on it will be burnt off in bronzing). The cast parts, and those not tinned (if any) are pickled in dilute oil of vitriol, and re-coured with sand, same as the body, and beat with a brush, then dried in sawdust, and is now ready for bronzing. Procure some crocus (which is an oxide of iron), and some knowledge is wanted to select a good one, as it may be too light, or too dark, or too fine, or too coarse, then make into a thick cream with water. Having used the fire to tin with, to be on the safe side it is best to raise out all the old coke and light afresh, and the coke should be a nice, clear, firm, grey one, and broke in pieces the size of a walnut, you must also have some nice clear, bright coal, then blow up a clear bright fire, and heap up plenty of coke that the sulphur may burn off, now take a little of the mixed crocus, and brush up the body, using a hard brush, get all the crocus off clean, and wipe with a clean piece of rag, and it is best to hold with this, as the perspiration of the hand will prevent the colour taking; now blow up fire, making a hole in centre, so that a good blast comes up, and having painted the body, evenly, so that the colour does not run (a flat camel hair brush, 2 1/2 in. wide, is the best thing to do it with), hold it with the tongs and turn it steadily so that all parts are exposed fairly to the blast. As soon as it is dry, throw into the fire a bit of coal about the size of a Spanish nut, more or less to size of work, and let the work have an even coat of smoke till it is quite black, but no more (if the coal is not burnt out hold the work on one side), then turning it steadily, keep up a sharp blast till the smoke is burnt off, then stand it to cool. Treat cast parts the same, but as soon as the smoke is burnt off, dip them into clean cold water, else, on account of their thickness the colour will burn, when cold, wipe the crocus off the body with wisp of clean tow, then brush hard till quite clean, wipe with rag and repeat the above once or twice, according to the shade required (to finish properly the body is hammered all over with bright hammers shaped to parts, and on suitable tools which are covered with 2 or 3 folds of larding), the inside is scoured bright, and the parts soldered together, using resin. This is the process to which coffee-pots and urns have to be subjected, and Chang will see that it is one requiring some amount of practical knowledge. B. Kingsland, p. 126, no. 38, wants to know how to bronze medals; he is answered by the above. Medals only want brushing up with wet crocus, taking care not to touch with hand, and then colouring as above. Only copper coins can be so bronzed.—GIVE AND TAKE.

SAFETY VALVE.—I find in answer to J. M. S., that his safety valve, as already loaded, would begin to blow off at 63 1/2 lbs, and that to blow off at 60 lbs, the weight would require to be placed 8 1/2 in. from the fulcrum.—SHREFFIELD.

GUN BARRELS.—In answer to Cina, who seeks information respecting the boring of gun barrels, I beg to inform him that the barrels are first firmly fixed in a clamp, having a leg to it, the leg is then inserted in the cup or socket of a sliding frame, which frame slides on a bed, either flat or two V's, or occasionally runs on wheels in grooves, and after the barrels are nicely adjusted to the centre of the boring shaft, a square broach about 12 inches long having a long shank to it, is inserted in the barrel and packed on one side (not on all four, as your article on Broches, in No. 87, affirms), with a wood split and paper, to fit the bore of barrel. The shank of the broach having been attached to the shaft, it is turned by means of a crank and fly wheel or steam power, and the frame containing the barrels is drawn forward as the broach cuts by a rope which is attached to it, passing over pulleys, and having a weight at its extremity. If Cina requires any more information, if he will forward you his address, I will communicate personally with him. Can any correspondent inform me how glycerine and nitric acid is prepared for blasting purposes, whether there are any other ingredients with it, and in what proportion they are mixed?—SOCRATES.

THE BOILER QUESTION.—I feel pleased with the manner which your correspondent A. Nelson has defended his boiler, and the good spirit manifested throughout his remarks. But some remarks he has made I should like to correct. He says, I do not understand the system of his boiler; now my objection was, that it did not possess the essentials of mechanical constructions, simplicity, and efficiency. Your correspondent sought by complicated means what was in his reach by simple ones. He says, that I prefer thick plates, quite a mistake; I prefer thin ones, and for that end could have weld bolts, by which means I would secure the greatest strength with the least material; and all advantages arising from a truly circular boiler, and absence of longitudinal joints and rivets. I am aware of the action of the flame on thick plates, but the boiler under discussion is an internally fired one, and the flame can only affect the flue, and that we have discussed previously. As to the objections to putting thick plates, the holes are farther from the edge, so that it amounts to the same thing,

and I find it to be so in practise. Concerning corrosion, there are so many theories that it would take too long to discuss them now; but it is best to remove all facilities for corroding as far as we possibly can. And, I may assure our friend, there is no difficulty in making a perfect weld. In reply to Robert Jenkins, I prefer the cross tubes attached to the boiler by Mr. Galloway, the patentee, for the reason that when furred up, and consequently injured they are so easily replaced. Wishing you every success in your efforts to diffuse knowledge and enable men to attain proficiency in their profession.—**ASPIRANT.**

PRESSURE OF CABLE.—Atlantic Cable wishes to know what amount of pressure the Atlantic cable sustains in depths of 30, 100, 1,000, and 5,280 feet. Rule:—Multiply the depth in feet by .434, the product will be the pressure in lbs per square inch. Example:— $1,000 \times .434 = 434$ pounds, the pressure at a depth of 1,000 feet.—**W. H.**

FAST SAW.—In answer to Butt Joint, I have to say that my fret saw will cut a 4-inch thick piece of hard wood, with the slow motion of the lathe, the saw then making about 120 cuts per minute. The length of the long arm of the elbow lever is 18 in., of the short arm (from centre to centre), 7 inches. With respect to the figured details, I will send next week full descriptions and drawings of a much simpler fret saw, which I have just completed. I hope this will also suit Mr. Herbert; but I can say of both these saws, that I work them on my lathe, (7 in. centres) with ease.—**THOS. E. MERRITT.**

VELOMOPED.—In reply to N. J. W., the entire wheels of velocipedes are very strong and light when made of oak, $\frac{1}{2}$ inch thickness of felly at the part where the tire goes on, $\frac{1}{2}$ inch thick where the spoke ends are entered, and $\frac{1}{4}$ inch deep.—**T. E. M.**

JAPANNING TIN.—In No. 39, in Notes and Queries, B. Hickman wishes to know the process of japanning tin trunks. If he will send me his address, I shall be very happy to give him the information he requires.—**FLANDERS OWEN.**

IRIDESCENCE.—I thank your correspondent for the information given about iridescence. But I find there is another way of producing it by the aid of varnish, which would better answer my purpose. I am informed that it is done in the following manner:—

The fundamental tint of the surface to be ornamented is laid on. A beautiful principle in optics is next brought into play—no colour is employed to produce the opalescence; the soap bubble exhibits its beautiful hues, although the water is nearly colourless, and so likewise it is in the present case. When a film of any transparent substance so thin as a twenty-thousandth or a fifty-thousandth part of one inch, there occurs what philosophers call an interference of light at the two surfaces, which produces colour, and this colour depends upon the thickness of the film, and the angle at which it is viewed. Each surface is covered by a careful process of dipping with an exceedingly thin film of a peculiar varnish, the process and the varnish being so chosen as to produce opalescence or iridescence.—**W. F. O.**

BRONZING.—In answer to B. Kingsland, I send the following taken from Charles Tomlinson's "Cyclopedia of Arts and Manufactures":—Copper coins and medals may be bronzed by the following process:—Dissolve in vinegar two parts verdigris, and one part sal-ammoniac; boil, skim, and dilute the solution with water until it ceases to let fall a white precipitate. The solution is then made to boil briskly, and is poured upon the objects to be bronzed, previously made perfectly clean from grease, and set in a copper pan, which is to be put on the fire and the boiling renewed. The pieces must be so arranged that the solution may be in contact with every point of their surface. The copper thus acquires an agreeable reddish brown hue, without losing its lustre, but it is necessary to repeat the articles every five minutes, and to remove them from the solution the moment the desired shade is attained. The pieces must then be washed repeatedly with water and carefully dried; if the solution has been too strong, the bronzing will come off with friction, or turn green by exposure to the air. An antique bronze appearance may be given by dissolving one part sal-ammoniac, three parts cream of tartar, and six parts common salt, in twelve parts of hot water. This solution is to be mixed with eight parts of a solution of nitrate of copper, specific gravity 1.180. When this compound is applied repeatedly in a moderately damp place to articles of bronze, it gives them a durable green coat which gradually increases in beauty; by increasing the proportion of common salt, a yellowish tinge is produced; by diminishing it, a bluish cast is obtained. A large addition of sal-ammoniac hastens the process.—**F. W.**

ANSWERS AND NOTICES TO CORRESPONDENTS AND READERS.

ALL letters intended for the Editor should be addressed to 75, Fleet-street.

LETTERS applying for information to be furnished by post cannot be attended to.

CORRESPONDENTS are requested to keep copies of their drawings and manuscripts, as the EDITOR cannot undertake to return such as may be rejected.

J. D. D. W.—We have enquired, but cannot learn.

D. GEMIC.—Thanks.

W. H. M. JONES.—Supposed to protect for three months, but a mere sham.

ENGLISH MECHANIC.—Received.

SOCRATES.—You are right. The repeated blunders are disgraceful.

HOMERIO BOOTH.—Yes—they rank as gentlemen.

W. H. G.—One of the best books published, but does not treat upon such subjects.

THOMAS GALE.—Too lengthy.

ENGLISH MECHANIC.—We advise you to stay the full term.

It is true that you can leave; but you cannot claim your indentures until you have served the full time.

WILLIAM MORGAN.—Refer to back numbers.

MECHANIC.—54, Old Broad street.

* * We have to ask our correspondents to sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them by the thousand; the same with "Well-Wisher," &c.

STRENGTH OF CEMENT.

At the meeting of the Society of Engineers, last week, the paper read was on "Experiments on the Strength of Cement, chiefly in reference to the Portland Cement used in the Southern Main Drainage Works," by Mr. John Grant. This communication related to an extensive series of experiments, the results of which were recorded in voluminous tables forming an appendix to the paper, carried on during the last seven years, with a view to insure, as far as possible, that only cement and other materials of the best quality should be employed in the Southern Main Drainage works, of which the author has charge as resident engineer. As a preliminary step, samples of Portland cement were obtained from all the principal manufacturers for the purpose of experiment. The average weight of these samples was found to be 108.6 pounds per bushel, and they sustained breaking or tensile strains at the end of a month, varying from 75 pounds to 719 pounds upon 2½ square inches. A clause was then inserted in the specifications to the effect that the Portland cement to be used in the works should be of the very best quality, and ground extremely fine, weighing not less than 110 pounds to the struck bushel, and capable of resisting a breaking weight of 400 pounds upon an area of 1½ inch square, equal to 2½ square inches, seven days after being made, and after being immersed in water for the whole of that time. The standard was subsequently raised to 500 pounds on the same sectional area, which was that used throughout the experiments. During the last six years 70,000 tons of Portland cement had been used in these works, which extended over a length of eighteen miles, and had cost £1,250,000. This quantity of cement had been submitted to about fifteen thousand tests, at a cost of only five farthings per ton. The machine devised for showing the tensile strain was a lever balance, constructed by Mr. P. Adie, and its first cost was from £40 to £50. It was so simple that an ordinary workman could be trusted to test the cement, and the cost for labour did not exceed £80 per annum for each machine. In conclusion, the author, whilst recommending Portland cement as the best article of the kind that could be used by the engineer or architect, warned every one who was not prepared to take the trouble, or incur the trifling expense of testing, not to use it; as, if manufactured with improper proportions of its constituents, chalk or clay, or improperly burnt, it might do more mischief than the poorest lime. Further experiments were desirable, on the strength of adhesion between bricks and cement, under varying circumstances; on the limit to the increase of strength with age; on the relative strength of concrete made with various proportions of cement and ballast; and on the use of cement in very hot climates, where probably extra care would be required in preserving the cement from damp, and keeping it cool until the process of setting had been completed. On these and other important points the author trusted that all who had the opportunity would record their observations, and present them to the Institution.

NOVEL INVENTION.

Some very interesting experiments took place on Tuesday week on board the *Mersey* screw frigate at Portsmouth, with West's electrical apparatus fitted on board as a warning indicator of possible danger to the ship from fire or water. A ten-cell battery fitted in the captain's cabin, with an indicator dial plate and an alarm bell, is placed in connection with twenty isolated copper wires, each of which communicates with a numbered section of the ship's hold, the latter being set off in twenty sections. Calorimeters connected with each wire are set at a given temperature, say fifty degrees above the normal temperature of that part of the ship, and the ever watchful sentinel for fire is then placed on permanent duty. If the temperature becomes increased from spontaneous combustion, or from a smouldering fire raised by other causes, the temperature has no sooner reached the heat at which the calorimeter has been set than the circuit is completed, the alarm bell violently and incessantly rung in the captain's cabin, and a number displayed on the dial showing the section of the ship in which the

dangerous heat is being generated. The rise of water in a ship's bilge beyond a fixed height is also indicated by the ringing of the alarm bell and the display of the section number. The calorimeter is a small metal vessel, some three inches in length, three-fourths filled with mercury. The outside of the vessel is in contact with one part of the copper wire of the section, the other part being suspended through the boxwood stopper in the neck of the vessel, the distance between the point of the latter part of the copper wire and the mercury being regulated according to the temperature considered dangerous. Should this latter event ever occur, the mercury necessarily expands, and, bringing the end of the wire in contact, the circuit is completed. The water signal is a piston enclosed in a chamber with the signal wire fixed at a certain distance—say two feet—above it. If water finds its way from any cause into the ship's hold, the piston rises with the water, and on coming in contact with the wire, the circuit is here completed, and the signal transmitted to the indicator dial and alarm bell. The signals on Tuesday were sent from all parts of the ship with unerring certainty, and with calorimeters set at various degrees of temperature, and with the water signal at varying heights. As the use of fire to raise the temperature of the ship below was out of the question, hot water at the required temperatures was used for testing the system and the manner in which it had been applied on board the *Mersey*. Her Majesty's ship *Valiant* is already fitted on the same principle, which is also to be applied on board Her Majesty's troopships.

OBTAINING MOTIVE POWER.

An invention was previously specified by Mr. Samuel Young, of Manchester (but protection was refused), relating to the production and application of motive power by the means of pressure of weight; and the improvements consist in the novel combination, construction, and arrangement of mechanism for applying the power so obtained to a crank shaft, so as to constitute an engine. The weights are to be applied in the form of ordinary "governor balls," connected to a slide, which presses upon one end of a series of bell crank levers, and so causes another lever to slide or move a cylinder, having a diagonal rib on its surface along a keyway on the crank shaft, which sliding movement causes the ends of two levers to act against the diagonal ribs, so as by their friction to effect the revolution of the cylinder and crank shaft, the opposite ends of such levers also transmitting motion to a sliding block or spring, which is connected by a rod to a crank on the crank shaft, from which the governor balls receive motion. Thus it will be seen that when the power of the engine is beginning to be spent, the weight of the balls, by falling and pressing the levers, maintains the working power. It will at once be seen that the arrangement could not work, because the weights have to overcome all the friction of the machine, and yet, by their fall, to raise themselves again. The refusal of the protection for such an invention is alike advantageous to the inventor and to the public.

PHOTOGRAPHY.

PHOTOGRAPHS ON IVORY, &c.—We notice in a recent list of American patents one by W. H. Smith, of London, for preparing wood, glass, silk, ivory, and other substances for the reception of photographic pictures. No particulars of the method are mentioned.

AN ALLEGED NEW PROCESS.—Mr. Fred Smith, of Leamington, writes to us to the effect that he understands that some one, whom he does not name, but resident in that town, is making claim to the origin of a new process of which he claims to be the inventor. As he does not name or describe the process, we are uncertain as to what he refers. He says:—"I enclose a print, from which you will see that although it is not as yet equal to silver prints, the agents I have used in printing are sensitive to light—the ingredients used by me being vinegar and oil, in proportion to three of the former to one of the latter. The print I enclose is merely printed, being neither toned nor fixed. I intend to make further experiments when time will allow of it. Should any of your readers procure better results I hope they will make it known to the profession." The print enclosed has the appearance of a rich, warm, chestnut-coloured print on plain paper. Mr. Smith has, however, omitted to state the object of the process, or the sensitive material used. The oil and vinegar referred to are doubtless used as the vehicle; but we are not aware that they are sensitive to light. We shall be glad to hear further from Mr. Smith.—*Photographic News.*

MUCILAGE BOTTLE.

The annexed cut illustrate a simple and effective contrivance for preventing the overloading of the brush of a mucilage or gum bottle, designed by Mr. E. H. Boswell, of Philadelphia, Pa. The improvement consists of an elastic band of india-rubber, A, applied to the brush and cap, in such a way that a free movement of the brush up and down through the cap is obtained when the brush is pressed upon, but

so soon as the hold is relaxed the brush is lifted entirely out of the gum by the action of the india-rubber spring, in place of soaking into the gum till the next time it is required. This is a considerable improvement, simple though it be, over the ordinary gum bottle in which, when nearly full, the brush becomes overcharged with the liquid, so that a greater quantity than is necessary is smeared over the paper. Here, however, a perfect command of the brush is obtained.—*Scientific American*.

IMPROVEMENTS IN LAMPS, OR APPARATUS FOR BURNING MAGNESIUM AND OTHER METALLIC SUBSTANCES.*

The object of this, the invention of Joseph Solomon, of Red Lion-square, and A. C. Grant, of Nottingham, is to feed forward, in a constant and regular manner, the wire which produces the light in magnesium lamps. As the light is produced by the combustion of the wire, and this latter gradually burns away, with a certain and uniform speed, according to the thickness of the wire, the feeding forward of the wire in a regular manner, to a given point, so as always to keep the spark or ignited end of the wire at the same spot, is a matter of great importance.

Fig. 1, is a vertical section of the lamp, and Fig. 2 is a front elevation of the same.

The magnesium wire is wound upon a spool or spools *a*, which are placed in a cylinder *a*¹, mounted on a stand, on which is placed a box, containing the clockwork movement *b*, which, when in action, draws the wire *a*², off the spools *a*, and passes through a tube *c*, and between a pair of feeding rollers, *d*, *d*¹, to a tubular holder *e*, from the outer end of which it projects, and, when lighted, burns with an intensely brilliant light. This spark or spot of light may be placed in the focus of a parabolic or other reflector *f*, *j*, so that the light may be thrown forward in any desired direction. The reflector is inclosed in front

by a case *f*¹, provided with a glass *f*², to protect it from currents of air. The whole apparatus is of an extremely portable character, and is provided with a handle *g*, whereby it may be carried or held in any position. This handle *g* should be cranked or bent down, so as to form a foot; so that, with the feet *h*², *h*³, Fig. 2, attached to the outside of the reflector, three rests, or supports, for the lamp will be formed. For some purposes the spools are dispensed with, and the wire is introduced, at once, to a pair of feeding rollers, which, being actuated by the clockwork, will carry it forward to the point of combustion. The wires may consist simply of magnesium, or of magnesium wire, twisted or combined, with wires or bands of other metal, such as zinc, cadmium, lithium, strontium, barium, or other metals, or alloys with magnesium. These metals, or alloys, when ignited, burn with different coloured lights, as will be well known to chemists and pyrotechnists; and, therefore, signals for naval, military, telegraphic, or other purposes, may be made with the magnesium, or alloys.

As a modification of this improvement, asbestos, cotton, flax, or other textile substance, capable of absorbing any concentrated solution, or preparation, of the above-named metals, may be combined with magnesium wire or bands. The best preparations for this purpose are the chlorates, nitrates, and chlorides of the metals.

sodium, potassium, or other alkaline metal with magnesium. This alloy will give a red, but strong, heat and light, and will greatly facilitate the ignition of the magnesium or other wire. To adapt this improvement, the alloy of sodium and magnesium is cut up into small pieces, and protected from the atmosphere, by being coated over with varnish, and then wrapped in tinfoil. One of these pieces is attached to the end of the magnesium wire by being squeezed on it, and when it is required to ignite the wire, this may be done at once by applying thereto a lighted match.

The patentees claim, "the general arrangement and construction of apparatus described for feeding forward magnesium or other wire, to be burned for lighting purposes."

THE INVENTOR OF ELECTRO-PLATE.

George Richards Elkington was born on the 17th of October, 1801, at St. Paul's-square, Birmingham. He was the patentee of the electro-plating and gilding processes, which he introduced commercially in the year 1840, and so rapid was the application of the principle to the manufacture of all kinds of articles, that from the small beginning of perhaps a score of persons employed by Mr. Elkington in the first instance, the firm which he founded now employ

SOLOMON & GRANT'S

MAGNESIUM LAMPS

* The next improvement consists in adapting to the break, or stopping mechanism *i*, of the clock movement a wedge *j*, which is introduced into the tube, containing the break lever *i*¹. By inserting this wedge *j*, above the break lever *i*, as indicated by dots in Fig. 1, the stop, or break *i*, will be kept out of action when the clockwork is required to be in motion. When the clockwork is to be stopped, the wedge *j*, is to be withdrawn, and the break *i*, will stop the movement.

Fig. 3 is a plan view, and Fig. 4 a side view of another mode of holding the stop lever down. In this instance the wedge is dispensed with, and the stop lever *i* is held down by a stud at the end of the flat spring *j*¹. As the lamp is mounted on three legs, it can be placed on a table or stand, and allowed to remain in any given position without being held by the hand. The tubular wick, or wire holder *e*, is screwed into its place, as seen at *e*¹, Fig. 1; so that, should it become damaged, it may be unscrewed, and removed with facility, and another holder, screwed in its place. This tubular holder *e* should, by preference, be constructed of platinum, or some other metal which is difficult to melt, or the tube may be provided with a platinum nose; the object of this improvement being to prevent the tube from being fused by the heat of the burning wire. The vapours evolved by the combustion of the wire escape up the chimney *k*, in which an upward draught is produced, by means of a fan or ventilator *l*, Fig. 2, which is worked by clockwork, as shown. The reflector case is perforated with holes *m*, *m*, Fig. 1, for the admission of air to the combustion chamber. The air, as it is drawn in by the ventilator or fan *l*, will ascend the chimney *k*, and pass down the flue *k*¹ into a vessel *n*, containing an acid or other solution, capable of taking up and absorbing the metallic vapours.

The next improvement consists in combining

upwards of 1,000 persons, and the trade has become one of the most important in his native town, where he may thus be said to have been the founder of an entirely new branch of industry, giving employment, directly and indirectly, throughout the United Kingdom to probably not less than 10,000 persons. His great enterprise and good taste have no doubt largely conduced to place the products of his works in the high estimation in which they are universally held. He was an extensive exhibitor at all the great international exhibitions, and never failed to carry off a large share of the medals and rewards that were obtainable. Though always desirous of encouraging native talent in all branches of his trades, he was still obliged to admit that in designing and modelling this country has still much to learn from the French, and he has, consequently, always employed both French and English artists in those departments. He was well known to be always ready to adopt any improvements in machinery—so much so, that any new methods of accomplishing any of his processes of manufacture were generally at once offered to him by the inventors, and his works at Birmingham now comprise all the leading improvements, and are among the standard attractions of his native town. He was also extensively engaged in copper smelting and coal mining operations in South Wales, employing several hundred workpeople, which businesses, as well as those carried on by him in Birmingham and London, in connexion with which he was more generally known, will now be continued by his sons.

His kindness of manner, just dealing, and unostentatious liberality were proverbial, and his death has been universally regretted. His death was caused by paralysis, and took place at his residence, Poolpark, Denbighshire, on the 22nd of September last. —*Journal of the Society of Arts*.

APPARATUS FOR BRUSHING HAIR.

This invention of Mr. Casimir Roques, Edinburgh, relates to certain improvements in the construction of brushes used for brushing the human or other hair, but is more particularly applicable to brushing long hair, such as that grown upon the heads of females. The apparatus consists of a rod or shaft upon which a pulley is rotated by the motion of a driving belt, the shaft or rod being furnished with handles, by which the operator holds the brushing apparatus against the head of the person or object to which it is applied. Upon the rod or shaft there is also fixed a frame of metal, at each end of which a roller is fixed; upon this frame the brush is stretched, and is caused to travel upon the rollers by means of a belt passing from a pulley (connected and driven by the driving pulley) on to one of the rollers which carry the brush. When stretched the brush is in the form of an oblong, with rounded ends, and in travelling one of its sides is applied to the head of the person or to any other object being brushed, so that, in contradistinction to circular brushes hitherto used, which tangle, twist, and break long hairs or filaments, the present construction results in a continuously travelling brush by which these difficulties are obviated, and hairs or filaments of any length can be easily and efficiently brushed. The brush itself consists of a strip of leather, in which the bristles or wires are fixed.

The engraving represents a front elevation, with the brush shown in section, of a brushing apparatus constructed in accordance with this invention. That portion marked A is a frame made of iron, or other suitable material. To one end of the frame, A, a round shaft or rod, C, is fixed in such a manner that it projects on both sides of the frame, thus forming two separate shafts, each of which receives a roller, B, revolving on it. At each side of these rollers is left a projecting edge to prevent the slipping off of the brush, which travels over them, as will hereafter be more distinctly described. Into the other end of the frame, A, the one end of a round shaft or rod, D, is screwed, or fixed in any other convenient way, or may be formed in one piece with the frame. The opposite end of the shaft or rod, D, has a handle, E, fixed to it, by which and by another handle, F, fixed at and to the frame, A, the apparatus can be held by the operator while in motion. Between the handle E and the frame A, a roller, G, made of wood, or other material, revolves on the round shaft or rod, D. It serves like the rollers, B, for the brush-belt to travel over, and to impart motion to the same, which is effected by a driving pulley, H, fixed firmly to the roller, G, or formed in one piece with this roller, and likewise revolving on the shaft or rod, D, so that, if the driving pulley is set in motion, it causes the roller, G, to move round in the same direction.

The brush, H, consists of a belt of leather, the ends of which are joined together, thus forming a regular driving belt. On the outside of this belt hairs or wires are fixed into the material of which the belt consists, in any convenient position. The inner side touches the rollers, B, working like one roller on the one end, and on a part of the roller, G, lying in a line with the former named rollers, B. If, therefore, the driving pulley is set in motion by means of a gearing moved by steam or other power, it causes the roller, G, as before mentioned, to revolve also, and this imparts motion to the brush-belt, H.

THE ROYAL OBSERVATORY AT GREENWICH.*

(Concluded from page 153.)

The reflex zenith tube, made on a peculiar principle, was designed by the Astronomer Royal, and constructed under his directions, by Mr. Simms, in the year 1851. The following is the principle of the instrument:—The star to be observed (γ Draconis) is so near to the zenith, that it may be seen with ease by an object-glass whose axis is immovably fixed in a vertical position. When the star passes overhead, an image of it will be formed at the distance from the lens equalling its focal length. If, however, a trough of quicksilver be placed below the lens, at half the focal distance, the image of the star will be formed upon the object glass itself. Should the mercury be placed at a distance of more than half the focal length, the image will be formed below the object glass; if at less than the focal length, above it. Assuming the lens to be truly placed, and a star to pass over it exactly in the zenith, when the star crosses the vertical axis of the lens its image will be formed exactly at the centre of the object glass. Should the star not be exactly in the zenith, it will not pass over the true centre of the lens, consequently the image reflected from the mercury will be formed at the same distance on one side of the centre of the lens as it entered on the other, the point between the two spots being the true vertical axis of the lens, and the true zenith. The angle given is the basis on which the calculations of the zenith distance of the star are founded. To find the true vertical line with which to compare each observation, a micrometer is attached to its moveable cell, and the micrometer wire placed upon the image of the star; the object glass is then turned half way round, the micrometer wire is again placed upon the same image, and, wherever the centre of the object glass may be, the vertical line which gives the means of computing the angular zenith distance is exactly in the middle of the space over which it was necessary to shift the micrometer wire. A little consideration will show that it does not matter whether the object glass revolves round its own centre, or any other vertical line passing through it. It is necessary that the azimuthal movement, or the movement of the lens round its vertical axis, be an accurate rotation round one vertical line, consequently the object glass must be carefully mounted.

The above is a section of the object glass, and upper part of the reflex zenith tube, the tube itself, and the cup of mercury below being omitted. S is the eye-end sliding in a socket. It comprises the third and fourth lenses of the eye-piece, or field-glass and eye-glass. R is the bent arm carrying the eye-end of the eye-piece. I is the flange of the sliding tube. Its edge is graduated for azimuth, the readings proceeding to 360 deg. I is the highest part of the sliding tube in which the rotating apparatus is inserted. I is the sliding tube. D is the fixed tube of the instrument. N, N, the two bars carrying the diagonal reflector. O, the diagonal reflector, a prism of glass. The inclined face and the lower or horizontal face are plane, but the vertical face is convex, and thus discharges the office of the second lens (counting from the object glass towards the eye) in a four-glass eye piece. The star γ Draconis, which is to be observed with this instrument, is not in the zenith, but nearly 2 min. north of the zenith; consequently the reflector O and the lens below it are placed, not over the centre of the object glass, but as far south as to correspond with 2 min. nearly. Q is a pointer attached to the frame of O, which comes nearly in contact with the frame that carries the micrometer wires, and indicates to the observer whether it is wire 15 or wire 16 which is viewed by the eye-piece. M, arms firmly attached to the sliding tube I, and which carry the bars N. h four handles, to move the rotating apparatus; g, flange of rotating apparatus; e, apparatus for relieving friction of the rotating frame; k, the cell of the object-glass; g, the short tube of the rotating apparatus which turns within I; l, the object-glass; this was formerly the object-glass of the 10ft. transit; its focal length is about

(* Extracted from the Engineer.)

10ft. 8in., and its aperture 5in.; s the upper, and p the lower micrometer bars; m a spirit level.

The following is an elevation of the north side of the instrument:—

The diagram at top of next column is a horizontal section of the upper part of the zenith tube, showing the rotating portions, though not in the position they occupy when in use.

The last refracting telescope at Greenwich, the one that yet remains to be described, is the great equatorial, the finest instrument of the kind in England. The telescope is used for viewing the planets, comets, and other heavenly bodies, whenever any interesting phenomena claim attention; it is, of course, the great object of attraction to visitors, yet it is little in request at the Observatory, where it is seldom used, and regarded somewhat as a magnificent philosophical toy. No observations involving calculations are ordinarily made by its aid, although in the great eclipse of the sun in 1860 it rendered most valuable assistance. The great object glass, which was made by Merz, a German, is 12½ inches in diameter, and many castings and partly ground lenses were rejected by him, before the present one was passed. A very few specks in the shape of minute air bubbles are visible in it. The great difficulty in optical glass is that it must be first brought in the furnace to a state of perfect liquidity to expel the air bubbles, and that in cooling the large proportion of lead it contains is liable to separate into layers which have more density, and are less transparent than the rest of the glass. The Americans have a much finer object glass at Boston, of fifteen inches diameter, and twenty-five feet focal

length. The object glass of the Dorpat telescope, at Pulkova, is fifteen inches in diameter also. All the framework of the great equatorial telescope at Greenwich was made by Ransome and Sims, of Ipswich, and the eye-pieces, graduations, and circles, by Troughton and Simms, of the Strand, London.

Some of the foregoing details will prove the excessive care taken to test the accuracy of the line of reference, the flexure of tubes, the true position of the pivots, and all the parts liable to error, the concurrence of each and all of which has a tendency to introduce inaccuracies in the calculations, and errors in time. These points being all known and provided for, it remains to register the true time of the passage of a star as it is seen through the telescope to cross the micrometer wires. One hand of the observer rests upon the end of the telescope near the eye-piece, and all he has to do is to tap with his finger a small button beneath his hand every time the star passes a micrometer wire. The true instant of time of each tap is recorded as follows, by means of galvanic chronographic apparatus.

A large brass barrel, revolving in two minutes of sidereal time by means of clockwork is covered

with a layer of woollen cloth. A sheet of paper is wetted, wrapped round the cloth, and its folding edges fixed by gum. This has to be ruled with one long line, in a fine spiral passing from end to end of the barrel, which to the eye appears to be numerous parallel lines passing all round the barrel, each of them only about one-tenth inch apart. A pricker is carried very slowly along the top of the barrel, and pricks a dot every second on the long spiral line on the barrel. It only makes fifty-nine pricks to the minute, leaving a blank at the sixtieth, which serves as a mark to distinguish each minute. Here then is a barrel, covered with a long spiral line, and a pricker marking the time on that line with chronometrical accuracy. But there is a second pricker, which only makes a mark when the observer of the passage of the star taps the button by the side of the eye-piece of the telescope, and these marks are pricked in the white space between the two lines,

so are at once distinguishable from the marks of the seconds pricker, which always fall upon the lines. The accompanying cut shows the manner in which the barrel is ruled, and seconds dots marked on the spiral round at regular intervals, the sidereal time of each second thus marked being known. When, however, a star passes the field of the telescope, the dots from the second pricker fall at different intervals between the ruled lines (vide cut), so, by comparison with the regular rows of seconds dots, the time of the passage of a star is recorded to the fraction of a second, and thus Greenwich time is obtained. This is afterwards transmitted to Mr. Varley's chronograph in the International Telegraph Company's Offices near the

Bank, and the chronograph sends it automatically to all parts of the United Kingdom, and in addition fires time guns in some of the northern towns. It sends Greenwich time direct every day to all the principal towns in Scotland, Ireland, Wales, and to a few on the Continent.

The prickers are moved by electricity. The circuit is completed through the electro-magnet of one of them by means of a toothed wheel on the transit clock, each tooth recording a second. The circuit through the other is completed by the observer every time he taps the button near the eye-piece.

The accompanying cut shows the arrangement of the prickers side by side, as they pass over the barrel, one of them being elevated and the other depressed. When the lines are to be ruled, a pen filled with ink

and water is substituted for the seconds pricker. The electrical circuit is broken, and the barrel directly connected with the heavy clock weight, which makes it spin round with great velocity, and a fine spiral line is marked on the paper. A feeble battery is used to do the regular work, having just sufficient power to bring down both the prickers, when they chance to fall at the same instant of time.

This refined piece of mechanism might naturally be supposed to complete the apparatus necessary to observe the passage of a star with accuracy, yet such is not the case. In using all delicate instruments the operator himself becomes a part of the mechanism. A locomotive may be perfect in all its parts, yet its speed depends upon the will of the driver. The telegraph companies are obliged to consider the clerks as an essential part of the instruments, a part also commercially affecting the interests of the shareholders, and the speed of transmission of messages through a given wire. This, for instance, would be felt by the shareholders in a successful Atlantic Telegraph, did the clerks send but one word, value 20s., through the cable in the same time they should

send two. It is the same at Greenwich, for unattainable perfection is required in the living part of the transit instrument.

A month or two ago we called attention in the *Engineer* to the curious fact that no two observers looking through a transit telescope see the same star pass the micrometer wires at exactly the same period of time. The French Astronomer Royal, in fact, has been recently making experiments to determine his own "personal error." It is just the same at Greenwich Observatory. The astronomers there rarely see the same star alike, one always sees it pass a fraction of a second before or after another, but this difference is nearly invariable. For instance, B, will always see it pass a little before A, and never a little after, except perhaps in case of illness, or other extreme disturbing cause. The more curious fact is, that there is no possibility of determining who is right or who is wrong, but the constant quantity of the variation, admits of a standard being chosen and considered as the right one, which it is for all practical purposes.

After a very long series of experiments the Astronomer Royal determined to accept Mr. Dunkin as the standard observer at Greenwich, and the following table shows the variation from the standard, or Mr. Dunkin, as deduced from those experiments. In the table (—) means "before," and (+) means "after."

Mr. Dunkin	D —	= 0.0 seconds
" Stone	D — S	= -0.14 "
" Ellis	D — E	= -0.16 "
" Criswick	D — C	= +0.16 "
" Lynn	D — L	= +0.29 "
" Carpenter	D — J C	= +0.07 "
" Dolman	D — M D	= -0.11 "
" Roberts	D — B	= 0.00 "
" Chappell	D — T C	= -0.12 "
" Nash	D — N	= -0.05 "

It will be noticed, however, that out of all these observers, two, Messrs. Dunkin and Roberts, chance to read the passage of a star alike. The figures applied for the correction of the observations of each reader are styled in England his "personal equation," and in France his "personal error."

Beyond the regular work of the Observatory, and the new calculations as to the distance of the sun, from the earth, little has taken place there recently of unusual public interest. Biela's comet is expected, but has not yet been seen, and Faye's comet is fast disappearing, yet during its present visit has not been once sighted at Greenwich, from the unfavourable state of the weather. Both these comets are very small and faint, and little can be made of them without a powerful glass. The sun was hitherto supposed to be 95,000,000 miles from the earth, but recent experiments at Greenwich, as communicated by Mr. Stone to the Astronomical Society, have proved the distance to be about 91,400,000. This was ascertained by careful observations of the planet Mars. The distance from the earth to Mars was not known, or from Mars to the sun, but the proportionate distance between the three bodies had been previously accurately ascertained. Mars gives the largest angle of any easily observable planet, and it was necessary to make the observations at a time when it was very near to the earth.

For many nights, when the weather was favourable, simultaneous observations of Mars were made at Greenwich, Pulkova in Russia, the Cape of Good Hope, and Williamstown in Australia. Mr. Stone put together the observations taken at Greenwich and the Cape of Good Hope, and Greenwich and Williamstown. Dr. Winnecke united those taken at Pulkova and those taken at the Cape. All the results taken at these different parts of the earth agreed very closely, and the sun has just been pronounced 3,600,000 miles nearer the earth than taught in the schoolbooks and primers of our younger days.

SOLDERING.

(Concluded from page 153.)

The copper tool, it should be understood, is applicable only to metals, as it requires such a degree of heat as will allow it to raise the temperature of the work to be soldered to the melting point of the solder; and the excess of heat thus required for stout metals is apt either to burn off the coating of solder, or to cause it to be absorbed into a superficial alloy. Thicker pieces of metal, which cannot be conveniently managed with the copper bolt, are first prepared by filing or turning, and each piece is then tinned by dipping, say for small pieces, into a ladle containing melted solder covered with powdered sal ammoniac. The flux meets the work before it is subjected to the heat, and the tinning is readily done. Larger pieces are dusted with sal ammoniac over the fire and the tin rubbed on to the surface—readily adhering if that surface be clean. The parts to be joined are then made a trifle hotter than for

tinning, and placed in contact whilst the solder is quite fluid, a little additional being added. The two parts, where practicable, are then rubbed together to spread the solder evenly through the joint and cooled under slight pressure. Many workmen, as mathematical instrument makers, are very successful with the blow-pipe in soldering; practice here gives the necessary observation and facility. Gasfitters are very expert in joining tin and lead pipes with the blowpipes; they cut off the ends of the pipes with a saw and file the surfaces to meet in butt joints, in mitres, or in T-form joints as required. In confined places heat is applied by them from one side with the blow-pipe and rushes, a rich tin solder being employed with an oil-and-resin flux. Mr. Holtzapfel says—"An ingenious workman assured me that he had employed this mode for lead pipes measuring externally 1½ inch in diameter and situated in angles by placing pieces of slate against the floor and perpendicular partition to defend them from the flame, the action of which was assisted by two pieces of charcoal inserted in the corners. And also, that as a trial of skill, he had made fifteen joints in ¾ inch tin pipe, five of each kind—plain, mitre, and T-form—including the preparations, in twenty-five minutes!" The pewterers employ what may be termed the hot-air blast, as shown in Fig. 6 in our last issue: the names for this apparatus are peculiar—a, in that figure (which see) being called a "hod," and b the "gentleman." The first is a common cast-iron pot with a close cover containing live charcoal; two nozzles lead one into the other from it to allow the passage of a stream of air through the pipe c, from bellows worked by the foot. The ware to be operated on is placed on the "gentleman"—a revolving pedestal, capable of adjustment to any height by means of a side screw. The operator dips the strip of solder in a little pot of oil, and applies the solder to the joint with one hand whilst with the other he revolves the work. The pewters bear nearly the proportion of the alloys Nos. 8 to 12 (see tables): for the less fusible containing most tin, the solder No. 8, or 2 tin 1 lead is used; for the more fusible, containing most lead, the bismuth solders, 2 tin 1 lead 1 bismuth, and others of varying fusibility are employed. By the table alloys can be exactly proportioned. The pewterer's flux is Gallipoli oil; it is a second-rate olive oil, thick and green.

In coating copper and brass vessels, they are first pickled with sulphuric acid—1 acid 3 water; they are then scrubbed with sand and water, washed clean and dried; they are next taken to the fire and heated, a bit of tin thrown in together with powdered sal ammoniac, a wiper of tow being used to sweep the tin over the heated surface, to which, if clean and sufficient flux dropped in, it really adheres. What of the tin is in surplusage—for a little goes a very long way—is wiped out into the ladle. If any "stubborn" parts are met with, where the tin won't "take," it is usual to take a piece of sal ammoniac fastened in a tongs and rub in the tin well and perseveringly. Iron presents more difficulty; the affinity of tin being less strong for it than for copper. The treatment, however, is the same. Old pots are well scraped with a sharp tool to get a fresh surface, and the pot heated to drive off any grease that will not yield to muriatic acid. Often the acid has to be boiled in the pot before the grease can be "spirited away." We have seen a small globule of mercury go an extraordinary long way in tinning a pot and bringing it out with a lustre equal to silver. By the way this is a capital plan in tinning jelly moulds of intricate pattern, the mouth being kept from over the work as much as possible whilst this volatile "flux" is being used. But the mercury should not be encouraged. It were better to purchase a new pot instead, there may be a positive gain in so doing.

In soldering "over edge" when the tin is brought down an inch or two over the outside, just paint up to the line from the bottom with whiting, that part won't "take" and the line assists the operator in his job.

Burning together differs from ordinary soldering, in so far as the metal used is the same as that of the pieces to be joined, and in general no fluxes are used. The method is an important one, as when cleanly done the works are very strong. Pewter is sometimes burned together at the external angles of works, so that no difference of colour may occur: the one edge is allowed to stand a little above the other, a strip of the same pewter is laid in the angle, and the whole melted together with a large copper bolt heated almost to redness, the surplus metal is filed off, leaving a good angle without any visible joint.

Brass is likewise burned together; for instance, the rims of large mural circles for observatories are

sometimes cast in half-a-dozen segments and attached by burning. The ends of the segments are filed clean, two pieces are fixed vertically in a sand mould in their relative positions, a shallow space is left around the joint, and the entire charge of a crucible is poured on the joint to heat it to the melting point. The metal overflows the hole and runs into a prepared sand-pit; but the last quantity of metal that remains solidifies with the ends of the segments and forms a perfect joint.

This week we have to notice the air-hydrogen blow-pipe invented by the Count de Richemont. It is in a great measure converting the oxy-hydrogen blow-pipe invented by Dr. Hare to the service of the workshop, and it is done with simplicity and safety. The elastic tube *h* supplies the hydrogen from the generator, and the pipe *a* supplies atmospheric air from a small pair of double bellows *b*, worked by the foot of the operator and compressed by the constantly applied weight *w*; the two pipes meet at the arch and proceed through the third pipe *c* to the small jet *f*, from whence proceeds the flame. All the connections are by elastic tubes which allow perfect freedom of motion. In soldering by the autogenous process the works are prepared as usual, the hydrogen is ignited and the size of the flame proportioned by the stop-cock *k*; the air is then admitted through *a* until the flame assumes a point, when the work is joined after the method of blow-pipe soldering, except that no flux is used and a strip of lead is used instead of solder. The best application of this method is to plumbers' work. The lead consumed in making the joints is nothing near that of the ordinary solder, which is more expensive, owing to the tin it contains.

which represents the generator about two-thirds filled with gas. The gas issues through the pipe *h*, when both cocks are opened, but it has to proceed through a safety box *6*, in which the syphon tube dips two or three inches into a little plain water introduced at the lateral pressure *7*; by this precaution the contents of the gasometer cannot be ignited, as, should the flame return through the pipe *h*, it would be intercepted by the water in the safety box. The liquid becomes converted into sulphate of zinc after two or three days' use, and is withdrawn at *8*; the vessel is then re-filled with dilute acid, but the zinc lasts a long time. We shall conclude this section in our next.

(To be continued.)

JORDAN'S PATENT FOR COMPOSITE IRON AND WOOD SHIPS.

JORDAN v. MOORE.—During the past week the above case of infringement of this patent was tried in the Court of Common Pleas, before Mr. Justice Byles and a special jury (of nine by consent). The invention in question is one of very great importance, and consists in making a complete skeleton or frame of the ship in iron, to which the external and internal planking (the latter technically called the "ceiling") can be effectually secured, in order to complete the perfect ship or vessel. The details of Mr. Jordan's invention, as presented in his drawings and specification, are that he uses a keel and keelson of iron (though there may be a partial substitution of wood for the iron), from which the iron ribs rise; the keelson also rising at the stem and stern, so as to form what may be termed an inverted arch (inside the vessel), for the purpose of

others, one by Mr. Watts, in the year 1814, in which the ribs were connected together and to the keel by what, although not the same in form, was in effect identical with the plaintiff's stringers; also a patent of Mr. Ditchburn's, dated 1841, in which truss-plates, so-called, were adopted, but which were substantially the same as the plaintiff's diagonal tie system.—After occupying the Court nearly three days, the case was decided in favour of the plaintiff. —The verdict being for 40s. damages.

IMPROVEMENTS IN ARMOUR PLATES TO VESSELS.

This, the invention of Mr. Edward Saunders, of Bridge-street, Westminster, relates to the use of screw and other bolts, spikes, and rivets of novel construction for general fastening purposes, and amongst others the fastening or securing of iron and armour plates to marine and other batteries, ships of war, and other vessels, in lieu of the solid metal bolts, spikes, and rivets hitherto used. When solid bolts are used in affixing plates of iron to the above structures, they are liable to be either driven through or shattered or broken by the impact of heavy projectiles; this liability increases as the size and consequent rigidity of the solid bolts is augmented, as in the case of thick and heavy plates, in fastening which it becomes necessary to increase the size of the bolts, in order that they may support as well as fasten the same to the under work. To remedy the above defect in these fastenings is the object of this invention, which is accomplished by making the body, shank, or centre part of the bolt, spike, or rivet of a number of wires, rods, or strands twisted, or so placed together that in transverse section they shall possess the required tensile strength, and at the same time a considerable degree of elasticity, and to make the heads and ends or points solid, by beating and welding, hammering, or compressing the same.

Lead is used in uniting zinc to zinc, and is also used in soldering the brass nozzles and cocks to the vessels of lead and of copper coated with lead used as generators. Another practical application of the gas flame is, for keeping the copper soldering tool Fig 2 at one temperature, which is done by leading the mixed gases through a tube in the handle, so that the flame plays on the back of the bit. This seems adapted to tinsplate and zinc work, and as the common street gas may be used, the gas generator to be described may be dispensed with. The generator, Fig. 1, somewhat resembles Peppys' gasometer. When first charged the stopper 1 is uncrowded and the lower chamber nearly filled with curling shreds of sheet zinc, when the stopper is replaced. The cover is now removed, and a plug with a long wire is inserted from the top into the hole near 3, the upper chamber is next filled with dilute sulphuric acid (1 acid 6 water) until it is just seen through the central hole to rise above the plate immediately beneath it. This measures the quantity of liquid required to charge the vessel without risk of overflow. The plug is now withdrawn from 3, and the cocks 4 and *h* being opened, the air escapes from the lower vessel by the pressure of the column of water which enters beneath the perforated bottom 5, upon which the zinc rests. The cocks 4 and *h* are now closed, and by the decomposition of the water hydrogen is generated, which occupies the upper part of the lower chamber and drives the dilute acid upwards through aperture 3, so as to place things as in the engraving,

strengthening the structure. The ribs are connected together by means of iron bands or stringers passing directly in the longitudinal direction from stem to stern, the ribs having also diagonal ties of iron, and iron ties which pass from side to side of the vessel, to secure the same transversely. It was admitted by all parties that a ship constructed as described would be a strong, seaworthy vessel; but contended by the defendant that the plaintiff's patent (a prolongation), was not valid and effectual in law, because he had in his specification claimed too much, or what was not new. He had stated in that document that his claim was in effect for a complete skeleton or frame of iron (i. e., a complete skeleton or frame, whether its constituent details be the same as those before enumerated or otherwise), and was not limited to the particular details he had described with reference to the drawings accompanying his specification; further, that he had made a distinct and separate claim for the mode of securing the butt-joints of several parts in the structure, which butt-joints consisted simply in placing over the line of junction, on the inner side, a piece of metal, with a waterproof packing piece secured to each of the two parts, joined together, and that this was a notoriously well-known method of securing butt-joints, as practised by carpenters, shipbuilders, and other mechanics. In support of the defendant's objections he so put in evidence several specifications of old patents (anterior to the year 1849, the date of the plaintiff's original patent), amongst

The figures illustrate several forms of the improved bolts, spikes, and rivets, in making which a good piece of wire rope is employed, the same being cut to the required length, and the heads and points or ends are forged solid. Instead of welding or forging the wires to form the head of the bolt, they may, in some cases, be spread out, and wedges driven in to spread them from the outside, so as to cause the whole mass to conform to the tapering hole in the plate, and then to cover it, if necessary, by any suitable kind of metallic or other packing.

The patentee claims, "the method of constructing a screw bolt, blunt bolt, spike, or rivet of wire or rods of any shape, in such manner that with a solid end, with or without thread, and solid or proper head, the shank or intermediate portion shall retain a certain degree of elasticity not possessed by any ordinary solid rivet, spike, screw, or bolt."

As an instance of the value of labour it has been shown by Mr. Babbage that the pendulum spring of a watch, which governs the vibrations of the balance, costs at the retail price twopence, and weighs the 15th of a grain; while the retail price of a pound of the best iron is only twopence. Out of that weight of iron fifty thousand such springs are made.

REVIEWS.

Tables for Workmen's Wages. By H. Laxton, C.E. London: the Author's, 34, Arundel-street, Strand, W.C.

We have been favoured with the two editions of this handy little work,—the "red book" for employers, and the handy folding pocket companion for the workman. The tables of which the book consists contain over 7,000 calculations, carefully corrected and simply arranged. Table No. 1 shows at any price per day the amount of wages per week, month, year, &c.; No. 2, shows at any price per year the amount of wages or rent per quarter, month, day, &c. Table 3, shows at any price per hour the amount of wages for any number of hours; and No. 4 gives at any price per day the amount of wages for any number of days, quarters, or hours. The whole affair is simply a very clear, well printed, and easily understandable ready-reckoner, which may well be recommended to both master and men.

A Treatise on Smoky Chimneys, their Cure and Prevention. By F. Edwards, jun. Third Edition, London: Hardwicke, 192, Piccadilly.

The days of smoky chimneys are not by any means gone by, though they ought to be; nor will they, so long as speculative builders run up cardboard houses and people are found to inhabit and suffer in them. Mr. Edwards' treatise is exhaustive and clever; it deals with the whole subject of our domestic fireplaces in a concise and understandable way, and if it were generally read could not fail to bring about some amendment in our present evil and wasteful course. It should be in the hands of all who can in any way influence the construction of fireplaces and chimneys. Our author instances fifteen causes for the non-efficiency of our chimneys, which we append, together with the approved remedies.

FIRST DIVISION.

Chimneys that smoke in consequence of a descending current existing, or being produced in the chimney, irrespective of wind.

Cause 1.—From a fire-place being too open. *Remedy:* To contract the size of the fire-place, or use a contracted grate.

Cause 2.—From the doors and windows of a room being fitted too closely. *Remedy:* To supply air by means of doors and windows, or to give a special supply near to the fire.

Cause 3.—From fires being lighted in two or three adjoining rooms, which are inadequately supplied with the air required by the grates in use. *Remedy:* To contract the opening into the chimney. To give an additional supply of air. To use grates that will not allow much air to ascend the chimneys.

Cause 4.—From a chimney being very short. *Remedy:* To use a contracted grate with a blower. To reduce the height of the fire-place and the size of the chimney. To lengthen the chimney. To reduce the opening into the chimney at bottom and at top.

Cause 5.—From a chimney being situated in an external wall, and not being sufficiently protected against the action of the external air. *Remedy:* To improve the construction of the chimney. To use a very contracted grate. To reduce the opening into the chimney at bottom and at top.

Cause 6.—From a chimney being exposed on two or three sides to the action of air; the exposed brickwork not being sufficiently thick. *Remedy:* To improve the construction of the chimney.

Cause 7.—From a low chimney being in connection with a room adjoining a house or building in which the air becomes rarefied. *Remedy:* To supply the house and room liberally with air. To fit tightly the door of communication, or use a double door. To use a contracted grate. To heighten the chimney. To reduce the size of the chimney.

Cause 8.—From a down current in a fire-place bringing smoke from an adjoining chimney. *Remedy:* To supply the room properly with air. To use a carefully fitted regulator to the chimney.

SECOND DIVISION.

Chimneys that smoke in consequence of a descent of wind.

Cause 9.—From the top of a chimney being situated below a pitched roof. *Remedy:* To heighten the chimney that its top may be above the source of obstruction.

Cause 10.—From the top of a chimney being situated near to a tower, or similar source of obstruction to the wind. *Remedy:* To heighten the chimney. To use a simple protection, as fig. 12.

Cause 11.—From a short chimney being enclosed on three or four sides by high contiguous buildings. *Remedy:* To heighten the chimney. To put a simple protection at top. To use the most contracted grate, and supply air below in moderate abundance. To reduce the size of the chimney or the extremities.

Cause 12.—From rooms with short chimneys being

situated between the main body of a building and a contiguous eminence. *Remedy:* To build the chimneys to the extreme height of the main building. To use the remedies indicated for Cause 4. To use a simple protection, as fig. 12.

Cause 13.—From chimneys of one house being lower than those of one adjoining. *Remedy:* To heighten the chimneys. To put a protecting roof as fig. 13 or 22.

THIRD DIVISION.

Chimneys that smoke in consequence of their being too small.

Cause 14.—From a chimney being too small for the fire-grate used. *Remedy:* To use a grate that will allow a minimum quantity of air to ascend the chimney. To re-construct the chimney. To use a stove.

Cause 15.—From two fire-places being used to one chimney. *Remedy:* To use well-contracted grates, with carefully fitted regulators. To supply rooms sufficiently with air.

Most heartily do we recommend the work to those of our readers who feel interested in fireside comfort.

The appended lithographic plates are good, and well supplement the simply written introductory and explanatory matter.

TESTING NITRATE OF SILVER.

BY PROF. TOWLER.*

The profit on nitrate of silver is not great, because the original substance from which it is manufactured—the base of the salt—is, in and of itself, a dear article. The same may be said of the terchloride of gold. On some articles apothecaries and druggists can put on a profit of two or three hundred per cent. without exciting a murmur against their exorbitant charges, because these articles consist of cheap materials to begin with, and may in appearance be sold cheap even when burdened with the immense percentage. Thus you may buy, and probably have bought, an ounce of sulphuric acid, for which with the vial probably you paid a quarter of a dollar; this price does not appear particularly out of the way, and yet the profit is immense! We do not know the exact quotation of the price of sulphuric acid at the present moment; the last we bought cost us in the carboy, if we recollect right, about two cents a pound, or one eighth of a cent per ounce—the vial is worth two cents—hence the profit will be a little more than a thousand per cent. A handsome profit!

It is impossible to exact the same grade of profits on the two salts just mentioned, as the reader can easily conceive. But because this is impossible, and the craving after unjust profits uncomfortably prevails amongst our very religious and moral people, this craving must be satisfied either by hook or by crook. They take the former experiment—they use the hook—and hook on to the real nitrate of silver and the real terchloride of gold some uncouthly substitute, as an alkaline, &c., nitrate or carbonate, whereby the prices of the too expensive salts may remain the same, whilst the profits gradually increase, as the consciences of the manufacturer gradually expand, like the inflated maw of a turkey.

It becomes our duty therefore, to instruct our readers how to test for the impurities in the adulterated articles.

Crystalline Form of Nitrate of Silver.

It is by far the best to buy nitrate of silver in crystals, and not as lunar caustic or as an amorphous powder. The form of the crystal, when pure, is tubular; so that if octohedral or prismatic crystals are described amidst these flat tubules, you may feel assured there has been an adulteration. If, on the contrary, the crystals are uniformly of a tubular shape, it is almost equally certain the nitrate of silver is pure.

Where there is any doubt, proceed as now directed. *Testing for Impurities by Chemical Reagents.*

Weigh out ten grains of the crystals, and dissolve them in distilled water; now add pure hydrochloric acid to the solution, drop by drop as long as there is a precipitate of the white chloride. Perform this experiment in the dark room.

Let the precipitate settle; and then add another drop of the hydrochloric acid in order to see whether all the chloride has been precipitated. If this be the case, separate the chloride by filtration, and wash the precipitate in several drachms of pure water, which is mixed with the first filtrate: that is, keep the liquids together.

The chloride may be that of lead or silver, it might also be that of mercury under certain circumstances, but it is not to be expected here.

Supposing that lead is present with the silver, we must now separate the chloride of the former from that of the latter metal by means of ammonia, which will dissolve the chloride of silver, and leave the

chloride of lead. If all the chloride is dissolved, we conclude that a salt of lead was not present in the nitrate of silver: and the contrary, if a portion was undissolved.

In the liquid, other metals, besides those of the alkali might be present; but it is not very probable. In order to be sure of this fact, the solution is first boiled for some time and then a current of hydrosulphuric acid is passed through the solution, when cool, for a short time; the solution is again boiled and set aside to cool, &c., for an hour or more. Or a few drops of sulphide of ammonia may be added to the solution instead of passing a current of hydrosulphuric acid through it; the solution is then boiled as before, until all smell of ammonia and hydrosulphuric acid has disappeared.

If there is merely a trace of a black precipitate, it is evident that several salts (nitrates that might be there) are absent. A copious black precipitate would indicate adulteration with either one or several metallic salts, not one of which, however, is likely to be the salt with which the adulteration might be successfully made.

Filter the solution and then evaporate it to dryness.

A white sediment (having previously removed all excess of hydrochloric acid by boiling) will indicate the presence of the nitrate of one or more of the alkalies or alkaline earths.

It would probably be the safer plan to evaporate the original solution at once to dryness, and then, if there is a sediment, to conclude at once that there is adulteration with the nitrates of one or more of the metals. The sediment is then dissolved and proceeded with, as above marked out, with hydrosulphuric acid, &c.

By proceeding in this way there is no risk of forming the chloride of ammonium, in case the sulphide of ammonium had been the re-agent used.

As the object of the operator is simply to ascertain whether the nitrate is pure or adulterated, it is not necessary to point out by what means the analysis may be completed so as to indicate the precise metal in the adulteration where it exists. Such an analysis would be long and without any special aim for the practical photographer.

PATENT LIST.

(From the Commissioners of Patents Journal.)

LIST OF SPECIFICATIONS, &c. PUBLISHED DURING THE WEEK ENDING 16TH DECEMBER, 1865.

122. Capillary hydrometer, R. A. Brooman—4d.
233. Sewing machines, A. C. F. Derouquigny and D. Gance—1s.
212. Tinsel for weaving and other purposes, R. A. Brooman—4d.
243. Steam boilers and furnaces, J. Twiss—1s. 10d.
244. Treating and applying tar oils, J. H. Johnson—4d.
245. Applying tar oils in manufacturing plant, A. H. Brandon—4d.
246. Obtaining sugar from starch, G. Haseltine—41.
247. Breach-loading fire-arms, S. Trulock, R. Trulock, and W. Trulock—4d.
248. Cotton gins, B. Dobson and W. Slater—4d.
249. Filtering apparatus, W. Bury—1s. 6d.
250. Rectifying alcohol, W. E. Newton—10d.
251. Washing wool and other fibrous materials, J. Petrie, jun.—4d.
252. Mortar and other mills, J. Raine—4d.
253. Breach-loading fire-arms and cartridges, W. Clark—1s. 10d.
254. Cartridge boxes, E. Blakelee—1s.
255. Drying wool and other fibrous substances, E. T. Hughes—10d.
256. Lantern for burning hydro-carbon oils, A. S. Macrae—4d.
257. Screw taps, W. Foster—4d.
258. Shaping hat and bonnet blocks, W. H. Higgins—1d.
259. Protecting metals from oxidation, J. Mc Innes—4d.
260. Steam engines, G. Davies—4d.
261. Extracting oil from waste fibrous substances, W. Teall and A. Naylor—4d.
262. Raising the wire ropes of lifting apparatus from strain, J. Gibson—10d.
263. Benzol, acid, F. A. Laurent and J. Cathelaz—4d.
264. Chimney pots, G. Carter—8d.
265. Breach-loading guns, &c., C. H. Russell and J. Needham—4d.
266. Lamp shades, R. A. Brooman—4d.
267. Fire and other alarms, M. Cartwright—4d.
268. Clothes fastener, J. W. Gill—4d.
269. Railway rail enclosing a telegraph wire, R. A. Brooman—4d.
270. Tanning hides and skins, W. H. Cox—4d.
271. Traction engine, M. Henry—8d.
272. Producing intermittent rotary motion, T. Hall and S. Bonser—1s. 4d.
273. Applying hydro-electricity to steam generators, J. Fletcher and D. Hauser—8d.
274. Lubricating apparatus, R. P. Colquhoun and J. P. Ferris—6d.
275. Railways, R. P. Colquhoun and J. P. Ferris—8d.
276. Firing pottery ware, J. Meakin—6d.
277. Breaking and scutching flax &c., J. Gray—4d.
278. Hot-pressing fabrics, A. Freeman—4d.
279. Horse hoofs and seed drills, J. Sastry—10d.
280. Portable chair, W. E. Geddes—4d.
281. Washing and drying wool, J. McNaught and W. McNaught—1s. 4d.

* Specifications will be forwarded from the Commissioners of Patents Office, Southampton-buildings, Chancery-lane, by post on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post-office Order, made payable at the Post-office, 3, High Holborn, or Mr. Bennett Woodcroft, her Majesty's Patent Office. We cannot undertake to forward Specifications, or Books advertised from the office of THE ENGLISH MECHANIC.

THE Imperial Society of Acclimatisation at Paris, which has just commenced its session of 1865-66, received during the past year twenty-five lots of seeds, of 118 different kinds, from America, India, China, and other parts of the world. The seeds have been divided into 840 parcels and distributed to 106 societies or individuals who had applied for them.

HOLLOWAY'S PILLS.—This purifying and regulating medicine should occasionally be had recourse to during foggy, cold, and wet weather. These Pills are the best preventative of hoarseness, sore throat, diphtheria, pleurisy, and asthma, and are sure remedies for congestion, bronchitis, and inflammation. Moderate attention to the directions around each box will enable every invalid to take the Pills in the most advantageous manner. They will thus be taught the proper doses, and the circumstances under which they must be increased or diminished. Holloway's Pills act as alteratives, aperients, and tonics. Whenever these Pills have been taken in the last resource, the results have been truly most gratifying, even when they fail to cure, they always assuage the severity of the symptoms, and diminish danger.

PATENT HOLLOW STEAM PACKING.

THE great and peculiar advantages of this packing consist in its remaining perfectly elastic, and is so constructed and applied that the pressure of the steam itself makes the joint by enlarging the packing from the cylinder; thus the many objections to packing previously existing are effectually removed.

Vulcanised India-Rubber Sheet Washers, Valves, Springs, Hoses, Glazed and Solid Tubing for Gas, Speaking Tubes, Diving Dresses, Gas Bags, Air-proof Goods, or any description of India-rubber articles made to order.

Prices list or circular, with full description of packing, to be had of the only Manufacturers and Patentes of Hollow Steam Packing.

FOSTER and WILLIAMS, India-rubber Works, Cowper-street, City-road.

ENGLISH MECHANIC:

A Record of Mechanical Invention, Scientific and Industrial Progress,
Building, Engineering, Manufactures, Arts, &c.

Vol. II.—No. 41.]

FRIDAY, JANUARY 5, 1866.

[PRICE ONE PENN

OBTAINING VARIABLE SPEED IN MACHINE TOOLS.

A PATENT has recently been taken out by Mr. John Combe, of Leeds, an engineer, for the invention of improvements in the action and management of drilling machines, turning lathes, and other machine tools, in which a variable speed is required, and which we have fully illustrated. The subject, our practical readers are well aware, possesses considerable interest; and we leave it for their consideration without any remarks of our own further than those necessary in explanation of the patent.

Figure 1 is a front view, partly in section, and figure 2 a plan, with some of the parts removed, of a drilling machine arranged according to this invention; figures 3 and 4 are side views of some of the parts.

a is an upright hollow pillar bolted to a foundation plate *b*, having four feet *b¹*, projecting diagonally to give stability to the upright pillar. In the centre of the plate *b* is fixed a step *b²*, to receive the pivot end of an upright shaft *c* passing down through the pillar *a*, capable of revolving freely in a socket *a¹* at the top of the pillar *a*. Immediately above the socket *a¹* on the upright shaft *c* is keyed fast a hori-

zontal disc *d*, the upper surface of which is turned true and level; above this disc *d*, another disc *e*, is also keyed fast on the upright shaft *c*; the disc *e* is turned on its lower surface so that the two surfaces of the disc *d* and *e* facing each other revolve in perfect parallel planes. The upper portion of the upright shaft *c* has a screw thread cut thereon, and is provided with a nut *d¹*, by which the two discs *d* and *e* can be brought into closer proximity to each other as required; above this nut *d¹*, on the shaft *c*, are placed the usual fast and loose pulleys *f*, by which motion is communicated from the driving strap to the machine. The shaft *c* is capable of being slightly raised or lowered by turning the screws *x*, and thereby raising or lowering the bar *z¹*, on which the bearing *b²* rests. A projecting bracket *a²* is cast on the upright pillar *a*; this bracket *a²* has a socket *a³* cast thereon, which is bored out in a direction parallel to the axis of the upright shaft *c*; through this socket *a³* the drill spindle *g* is capable of revolving freely, being retained therein by two collars *g¹*, which fit against the upper and lower ends

of the socket *a³*. On the upper end of the drill spindle *g* is keyed a horizontal disc *h*, which is turned true and level on both sides and is placed between the two discs *d*, *e*, carried by the upright shaft *c*. The three discs *d*, *e*, and *h* are of such diameters respectively that their circumferences intersect one another to about one-third of their diameter. A pair of friction rollers *i* with solid leather surfaces are suspended on rods or bars *k* forming a kind of parallel motion working on two studs *k¹*, carried by the projecting arm *a⁴* on the bracket *a²*; these rollers *i* are so placed respectively between the three discs *d*, *e*, and *h* that the friction of the discs *d*, *e*, carried by the driving shaft *c* transmits motion in an opposite direction to the intermediate disc *h* carried by the drill spindle. The parallel motion which carries the friction rollers *i* is so arranged that the rollers *i* are capable of being traversed sideways to and fro between the axes of the driving shaft *c* and the drill spindle *g*, so that the nearer the friction rollers *i* are brought to the driving shaft *c* the slower will be the speed of the drill spindle *g*.

and *vice versa*; the friction rollers *i* are capable of being fixed in any required position between the driving shaft *c* and the drill spindle *g*. On the lower part of the upright pillar *a* a bracket *l* is cast carrying a short socket or boss *h*, the axis of which is in a line with the axis of the drill spindle *g*. This socket or boss *h* is bored out to receive a brass nut *k* through which an upright screw *m* is passed, on which the table *n* which carries the article to be drilled rests; by means of the screw *m* the table *n* is raised and lowered as required. The table *n* is provided with four sockets which slide freely on two upright parallel bars *o*, so as to cause the table *n* to rise and fall in a vertical direction when acted upon by the screw *m*.

In order to secure a perfect balance, as well as economy in the construction of these machines, they are made double by casting on the pillar two sets of brackets on opposite sides carrying two tables and drill spindles, to which motion is given by one pair of discs *d*, *e*, and one upright shaft *c*. Some of the parts are shown repeated on each side of the machine, marked with similar letters of reference. When it is required to drill articles of greater length than could be accommodated on the tables *n* or *n'*, the table *n* and the bracket *l* are turned out of the way, and rest the article to be drilled on the ground. For this purpose the rod *q* is removed from the machine and the table *n'* is turned upon the rod *q* to one side, whilst the bracket *l'* is turned on the pin *h* out of the way when set at liberty by removing the set screw *h*. That the drill may be capable of approaching to and receding from its work, the upper part of the drill spindle *g'* is formed with flat sides passing through a socket *g''*, so that the drill spindle is capable of rising and falling through the socket *g''*, and yet controlled to rotate therewith; on the socket *g''* is fixed the disc *h'* as shown; the upper end of the drill spindle *g'* is extended through the socket *g''*, and its upper end is formed to receive a pin *g*, which is capable of revolving therein, but is secured thereto by a screw cap *g₃* as shown. By reference to Figure 4 it will be seen that the pin *g* is at its upper end pin-jointed to the arm *p*, which is at one end pin-jointed to a link *p₁* connected to the bracket *q* as shown, whilst the other end is provided with a nut capable of turning therein, through which a screw *r* passes; the lower end of this screw is provided with a handle *r₁*, by turning which the drill spindle *g'* is raised and lowered as required. In applying the differential motion to turning lathes, the intermediate disc *h* is placed on the back end of the spindle of the fixed head, and to overhang the bearing, so that the circumference of the disc *h* may extend below the level of the gauntry. Arms projecting from the cheeks of the fixed head carry bushes in which revolves a shaft *c*, carrying the belt pulley and the two driving discs *d*, *e*, for each fixed head, the studs carrying the parallel motion for traversing the friction rollers being fixed to brackets below and at the back of the gauntry. In a similar manner would a like motion be applied to other machine tools requiring such motion: and the inventor is of opinion that a competent workman will readily make the modifications necessary in adapting it to other machine tools.

THE CARDIGANSHIRE mines yielded, in the time of Charles I., 80 ounces of silver in every ton of lead, and part of the king's army was paid with this silver, which was minted at Shrewsbury.

GLASGOW INDUSTRIAL EXHIBITION.—Last Tuesday morning this exhibition was formally opened by the Duke of Argyll, in presence of a large assemblage. In the evening, a crowded meeting was held in the City Hall, at which the Duke of Argyll delivered the inaugural address. He took for his subject, "The agencies which have been and are brought to bear on the condition of labour in this country," and spoke at great length on the agencies of legislation, of voluntary combination among the working classes, of municipal government, and individual thought and action.

ROTATING BELLS.—Mr. Harrison, of the American Bell Company, has devised a means for preventing the fracture of bells, arising from the continuous pounding of the tongue in one place. For this purpose the bell is hung loosely upon a round bolt, which is suspended by a spur wheel made fast to the bell. This wheel communicates by a simple train of gearing to a lever on one side, which is actuated by a cam as the bell swings, and which turns the gearing by a pall and ratchet wheel, so that at each stroke of the tongue the blow is given on a fresh part of the bell. It is asserted that the imparting of a very slow rotation to bells, as above described, prolongs their durability indefinitely.—*Scientific American*.

TO ADVERTISERS.

As the ENGLISH MECHANIC addresses itself to the largest and most intelligent portion of the community, and is the only Paper of the kind established, it offers unusual advantages as an advertising medium.

The English Mechanic.

FRIDAY, JANUARY 5TH, 1866.

IMPORTANT TO THE READER.

IT has been represented to us from time to time, by various correspondents, that the pages of the ENGLISH MECHANIC were over-crowded with advertisements and the general contents frequently too densely packed together; the paper on which the journal has been printed scarcely substantial and high-class enough for a work to be placed in the home library as an authority of frequent reference for many years to come; and generally that an article much superior might be given. All such complaints or suggestions—for they have come to us more as suggestions than complaints—have frequently been taken into deep and earnest consideration, and we have at length determined upon adopting at least such as shall do away at once with the necessity for complaint concerning the appearance of our journal; and, to achieve this desirable end, we need scarcely add, we require the co-operation of our readers. And thus, while we announce that the next number of this journal will be increased in size, and the MIRROR OF SCIENCE incorporated with it; that the work will be printed on a superior paper, with a clearer type and contain many more and varied articles on scientific matters,—we have to state that the price must be raised to TWO PENCE.

The cost of all articles worth having is on the increase—labour has advanced, and is advancing in value, while the hours for labouring are being reduced. We have consistently and warmly advocated the attainment of these blessings; and the fact of advances having taken place entails on us the necessity of raising our prices. We desire as much as other folks to live by our labour, and we can do this only by adopting the course above indicated. It is utterly impossible for a class paper as ours is—to be the organ of the Mechanic, and scientific student and be really acceptable—to pay its way and return a fair percentage on the necessarily heavy outlay connected with it, at the present very low figure. In every possible way have we tried to work it, but have been forced unwillingly to the conclusion that twopence is the lowest figure at which we can henceforward publish THE ENGLISH MECHANIC and MIRROR OF SCIENCE with the various improvements in size and appearance above indicated.

Here it may not be uninteresting to remark that the increased price has been often forced upon our attention by correspondents so far back as eight months ago; but as we had started at a penny—the popular price of the day—we could not think of agreeing to the suggestion of increased charge until every possible means of obtaining a return for the capital expended had been tried. It does not come with a very good grace from those who advocate increase of wages and reduction in working hours to beat down the prices of their own workpeople: we do not care to do this, and feel certain the readers of the ENGLISH MECHANIC are not the men to patronise people who do so. We confidently appeal to our subscribers to support us in the step we are about to take. In all respects they will have a much better article, and those who work for them will do so with a better heart, as they will then, it is confidently hoped, receive a reward commensurate with their labour.

In conclusion, we have simply to repeat that in the next number the size of this journal will be increased—that THE MIRROR OF SCIENCE will be incorporated with it—that it will be printed on a superior class of paper with clearer type—and, that its price will be TWO PENCE.

"THE YEAR THAT'S AWAY."

WITH however much pride a merchant posts up his balance at the year's end, when he has closed his books and leant back in his chair, there steals into his mind thoughts manifold concerning things left undone, things that ought to have been done, things to do which no chance will ever again present itself. And when these have elbowed their way through the audience chamber of the brain, then gradually steal in thoughts of those who have, like the year closed, passed away for ever, ferried over the dim unsounded stream which margins Time. So we, after passing the year in its varied aspects before us, have also passed before our mind's eye the names of the departed men great or well known in their vocation; though we have thankfully to admit that the list is small compared with those of former years. Among the "passed on" we have to note Struve, the Russian astronomer; Silliman, the well known American chemist; Professor Boole; Neilson the engineer; Cobden, Paxton, Lubbock the mathematician; Parnell the architect; Kiss the Prussian sculptor; Appold the civil engineer; Richardson the lexicographer; Sir Charles Eastlake, and various others whose loss will long be felt, and who will doubtless be long missed from the fireside; for, after all, it is there the loss is longest felt. But while we deplore their loss let us be thankful for much that is good, for much that promises well remains behind to "fall in" to the places in the ranks vacated by the departed.

Few trades have had to mourn bad times during the past twelve months; the close of the American civil war has tended to settle things down, and they are, generally, firmer than they were at this time last year. Mechanics generally have had a fair "spell" of it; this we conclude from having heard no complaints. And the prospects for the year now starting down the incline are more favourable than they were for "the year that is away" at this time twelve months since.

There have been so many improvements in machinery that to notice them would simply be to fill our journal with nothing else. There have been a few "steady-going" improvements in the locomotive, a capital little tell-tale for the state of the atmosphere in mines. Great progress has been made in coal-cutting machinery, and we understand that various others will shortly be before the public. In nail and spike-making machinery there have been sundry improvements, as also in wood-sawing and planing machinery. Rivetting, cutting, shearing, and punching machines and roll-trains have had considerable attention devoted to them, and a capital invention has come to light for cutting sugar in dice of any size at any decided rate per hour; this by Mr. William Muir. In girder-bridge building there have been marked improvements, and the Bessemerising process has become a great fact. Nor has ship building and engineering lagged behind, though the consumption of fuel per horse-power per hour is scarcely the thing yet. Attention has been directed to the burning of oil fuel, and great progress has been made with petroleum, especially in the furnace, which contains two layers of fire spaces to the one used for coal; indeed, hopes are held out that this fuel may yet be found more economical than coal. In agricultural machinery there have been very few improvements, but we are glad to notice that E. E. Allen's engine is receiving the reward it deserves.

But here we must call a halt—our space forbids enlarging on the tempting theme. But everything tends to show how, day by day, the English mechanic becomes more and more valuable, and shows how capable he is to stand alongside the mechanics of any other country. That he is valued, witness the exports of machinery to all parts of the world, and the falling off in some of the imports, the articles of which our own workmen now supply at as cheap a rate and as good as those which used to be obtained from abroad.

On the whole, we have every reason to be thankful for our position, and to strive to better it in the time to come. There is room for it, and we are glad to see the right spirit is abroad. We judge this more from the letters of our myriad correspondents—who date from all parts of the country—than from anything else. They exhibit a rare degree of intelligence, which augurs well for the future. We heartily wish them all success in business, and if they will be but true to themselves and to each other they will achieve success not only in 1866 but in all time coming.

THE PAST YEAR'S INDUSTRIAL EXHIBITIONS.

PROPERLY looked at, it cannot be doubted that industrial exhibitions are a great benefit, to the

employer as well as the employed. The careful production of even the commonest piece of goods for "show" engenders habits of precision and general care on the part of the workman, which must enhance his value in the eye of a thorough-going employer. And it may safely be affirmed, not only that the man who studies neatness in his "exhibition work" bestows more care on that which he produces for bread than the man who has no ambition to exhibit, but that the man who turns his attention to innovations on things as they may happen to be within his own ken, is also a handy man in the workshop, and gets over many a "shift" which your regular routineer could only sit down and muddle over when difficulty to be overcome came in his way. This, in our own experience, we have always found to be the case; and any one who has taken the trouble to enquire "in and among" workmen at the various exhibitions will have found the correctness of our statement to be beyond impeachment.

Among industrial exhibitions that of the first South London (though not of the past year) claims priority of mention—originating with a Lambeth missionary, Mr. C. M. Murphy, and held in the Lambeth Baths building. Here to exhibit came chimney-sweeps, postmen, sailors, gardeners, corkcutters, and workmen of all kinds. The sweep showed a water-filter of his own improved construction; the postman exhibited a table-cover with nearly 5,000 diamond-shaped pieces in it; a hairdresser came out in plaster-models, and a painter in anti-garrotting cravats. So great was the success of the South London Exhibition that one was started for north London, and held in the Agricultural Hall, Islington. It was open for less than three weeks, yet during that short time within a very few of 200,000 persons paid it a visit, and the receipts exceeded the expenditure by £800. There were nearly a thousand exhibitors, and the articles were an improvement on those at Lambeth. In February, 1865, Lambeth Baths was the scene of a second exhibition—a most unqualified success, reflecting credit on all concerned in it—from the humblest exhibitor "only 7 years old" to the president. Various exhibitions followed these, dictated, probably, by different feelings—at any rate they had not the same success. That at the Floral Hall, Covent-garden, was a remarkable failure, that at the Beaumont Institute, Mile End-road a ditto; one held in nearly the same locality—the St. Mary's Schools, White-chapel-road, met with a different fate. Many of the articles exhibited were of a superior kind, and 50,000 people went to look at and admire them. The one at Wandsworth was a success; here were exhibited an A 1 Berlin wool ship by a bricklayer; headwork by a soldier; violins by bricklayers; boots by a newsboy; and an engine by a hatter! Then there was a Juvenile Industrial Exhibition at the Agricultural Hall, in which Reformatories came out brilliantly. Here was exhibited the Great Pyramid made, as facetiously remarked, by 'Apenay Bundle, Esq. It was built of some 4,000 bundles of firewood, was hollow, and had a goodly-sized room inside. Then there was the Anglo-French Exhibition at the Crystal Palace, which was not a working man's exhibition, and so failed. We have, we think omitted several London minor exhibitions, but we have named sufficient to show that they were, on the whole, a success, where properly managed. But it would be unfair to pass over the fine display at Greenwich, by the sou'-easters. There were some capital pieces of mechanism and of finished works, model and otherwise, which preach a fine lay sermon in favour of the working man. In the country there have been many important exhibitions. At Wakefield there was a very creditable one—in which was a very fine display of "union cloths," the production of Morley manufacturers, and illustrating a new branch of textile industry. Nottingham and Reading also came out very creditably, and Birmingham had one in which there were nearly 800 exhibitors, principally handicraftsmen of the town and outlying hamlets. The exhibition of the Preston folks was so great a success that over £2,000 were cleared after everything was paid for. Bristol produced 700 exhibitors, and some excellent models of yachts and other vessels. Then there was Plymouth and Manchester—a fine display—and lots of other places. A few useful ones cropped out here and there in Ireland, not to mention its great exhibition in Dublin; and Scotland, as usual, is to the front—the one now being held in Glasgow being a fine affair—supported by gentlemen of all positions inside and outside of Glasgow. Though we have gone so far afield we have yet room to notice the Coachmakers' Exhibition, nearly a year since, in Cheapside, which while it went far to show the substantial and useful character of our English coach-

makers' work, at the same time made evident that in matters of design and art they have still a great deal to learn.

One thing was evident in every exhibition, and that was that a fearful amount of ingenuity and patience had been wasted—utterly thrown away. Many things exhibited might be wonderfully constructed but they were hideous abortions. The getting-up of such things is not to be commended. For instance, what is the use of making a chain of half a hundred thousand pieces?—or a counterpane with has many pieces in it and unnumbered stitches? It is simply throwing away valuable time—it is worse than that, it is wrongly using that which is given for quite a different purpose by an Allwise Benefactor.

One great good these exhibitions have done—and that is, it has made master and man rub shoulders often where they might never otherwise have done so; it has brought working men into the society of competitors, and led many to see in what they may have been deficient. What the present year will produce we cannot say; though we believe there are several about to be set on foot, not only in London but in various parts of the country.

We should like to see these grow from regular centres of art or science education. We might then look forward to many working men's works as we do now to those exhibited at the Royal Academy and other artist exhibitions. What our opinions are respecting the ultimate objects of Working Men's Industrial Exhibitions has already been placed on record in these pages; and we see no reason to alter the opinions then expressed;—simply to add that we wish them every success possible in 1866.

PROGRESS OF INDUSTRIAL EXHIBITIONS.

Since 1851 we have become familiar with exhibitions, and the familiarity has probably done something to take off the edge of novelty; but there is a peculiarity about the Glasgow Exhibition rendering it worthy of special attention;—it is mainly the creation of working-men. A number of the more opulent citizens have, indeed, contributed of their "art treasures" to its adornment, but the mass of the contributions are either those of artisans or amateurs. The preponderance of models of the locomotive and steam engine, reminds us that Glasgow is the city of Watt, and that the determination he gave the mechanical arts has left an abiding impress upon its genius. Who first originated the idea of "exhibitions," it might perhaps be hazardous to say. "But there can be no hazard in asserting that to the sagacity and the labours of the Good Albert, was Britain indebted for the splendid success of the Exhibition of 1851. The Consort of our Queen comprehended more profoundly than most men of his time, how, despite the "confused noise of the warrior," ever and anon breaking on the ear of Europe, the age is, after all, essentially an industrial age. The Great Exhibition, over which he presided with such remarkable ability and unwearied perseverance, was the realization of that fact. Glasgow, albeit, the second city of the empire could not expect, in a purely local enterprise, to cope with an enterprise to which the industry of the world sent its wealth. In the London Exhibition there was gathered as into a nest the riches of nations, while Glasgow working-men have only the spoils of a single city to select from. But even in the more modest dimensions this enterprise assumes, the great lesson of industrial exhibitions is taught with a vividness and force that at once arrest the most listless visitor.

The large building in which the exhibition is held at 99 Argyle street, contains four large flats, with ante-rooms. The ground floor of the exhibition contains upwards of one hundred models of stationary and locomotive engines of varied and novel construction, ingenious mechanical apparatus, extensive collection of coloured and photographic mechanical illustrations, specimens of artistic relief, works in malleable iron, &c. Then in the first gallery, in addition to the bust of the Prince Consort and Messrs. Wylie and Lochhead's drawing-room, there are groups of statuary, richly inlaid cabinet and glass work, collections of Chinese and other foreign ornaments and curiosities, valuable contributions of articles of vertu in gold, silver, enamel, and alabaster, and ladies' fancy work of all kinds. The second gallery embraces an extensive collection, illustrating to a very minute and admirable degree, the sciences of geology, botany, zoology, mineralogy, and ornithology; also, microscopes, aquariums, illustrations of chemical products, electric clocks, and illustrations

of the mechanical powers. The third gallery contains contributions from gentlemen possessing the finest art collections in the West of Scotland, and others, embracing Holman Hunt's great painting of "The Scape Goat," Macculloch's "View of the Clyde," MacLise's "Sleeping Beauty," Knell's "Battle of Trafalgar," MacLise's "Scene from Othello," Ansdell's "Return of Montrose from Raid with Booty," and other equally valuable paintings; also, portraits and busts of eminent gentlemen, and paintings, drawings, and designs by working men. In the photographic gallery are specimens of the art from the best-known firms in the profession; also interesting private collections, including—"Scenes from Faust," "Views of the Holy Land," "Views of Scottish Scenery," miniatures, portraits, &c., &c. Ante-rooms are set apart for operatives engaged in the manufacture of needles, glass ornaments, brushes, weaving of plaids, &c.; also, two large glass engines are in constant motion. Arrangements have also been made for exhibiting George Cruikshank's great painting "The Worship of Bacchus."

Such is a sketch of the contents of the Exhibition of Industry, Art, and Skill which has been provided for the vast working-class population of the West of Scotland. It may be stated generally, that the articles exhibited by working people number nearly 1,400; and that the exhibitors belonging to the industrial classes are upwards of 500, showing how general the response has been to the desire of the promoters, to make this a most successful, because interesting and instructive Exhibition. We have no doubt large numbers of the townspeople will avail themselves of this opportunity of viewing one of the finest displays which has been witnessed in the form of a local Exhibition.

REFINING LEAD—John J. Crooke, of New York, claims the improved process of refining impure lead by treating it while melted with the melted oxide of lead.

ATMOSPHERIC FORGE HAMMER.—An improved and very efficient forge hammer is at present being manufactured by Messrs. Merrill and Sons, of New York. The 10-lbs. hammer occupied but 4 ft. by 2½ ft., and runs with but little noise, and no jar beyond the blow on the anvil or work. The cylinder and hammer move in vertical slides, so that each blow is square, and exactly in the same place; it is under the perfect control of the workman, who can strike light or heavy blows, and at any speed, and it is claimed that the working parts are not liable to get out of order. The hammer derives the increased force of its blows from compressed air. The cylinder is air-tight at each end, and there are two small holes in the side of the cylinder near the centre through which the air passes freely in and out. It will be noticed that the piston, piston-rod, and hammer are entirely independent of the cylinder, and can be moved up and down without moving the cylinder; also, that when the cylinder is moved either way the piston passes the air ports confining the air in either end of the cylinder, which prevents the piston striking either head, and acts as a spring, lifting the hammer up, or accelerating its downward movement. The cylinder has a definite motion, governed by the travel of the crank, but the hammer has more lift, owing to the compression of the air. If the cylinder is moved up and down slowly there is no blow given, as the weight of the hammer rests on the cushion of air, under the piston in the bottom of the cylinder. If the cylinder is moved up quickly the air under the piston strikes and lifts the hammer as quickly, and the momentum of the hammer in its upward motion causes the piston to pass the air ports, and compresses the air more or less according to the speed in the upper part of the cylinder; the elasticity of which, acting as a spring, accelerates the downward motion of the hammer, to which may be added the rapid downward motion of the cylinder following up and crowding the air spring upon the piston, adding to the force of the blow. The blow is controlled by the speed; the sharpest blow is given when run at high speed. It can be run rapid, and strike lightly by lengthening the connecting-rod, which allows the bottom cushion to receive the bulk of the blow. There are no valves to get out of order; the packing is exceedingly durable and easy working; both that in the piston and lower cylinder-head are made of the cup leather used in packing hydraulic rams, and they have been run for months without perceptible wear.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents.]

TEMPERING MILL CHISELS.

As a contribution to your Christmas number, allow me to offer the following for tempering mill chisels, edge tools, springs, &c.:-

1 ounce white arsenic, 1 ounce spirits of salts, 1 ounce sal-ammonia dissolved in four gallons of spring water, and kept in a tube or iron phial for use.

Heat the spring, &c., to a b.o.d.-red heat, then quench in this mixture, draw it gently over the clean fire till a spittle flashes off it, then let it cool.

The above I have used for mill chisels (without taking down) made from unkind steel, and with success, but have not tried it for edge-tools and springs. Perhaps it may help to solve the question suggested in your late article on Hardening Steel, and in which arsenic is mentioned as the doctor for water.

LUTON.

HOROLOGICAL.

Sir,—I think that many readers of THE ENGLISH MECHANIC would think it a treat if you occasionally gave information on clock making. I myself am exceedingly fond of all connected with the art, and at the present moment am at a loss how to set about making a timepiece, while I am I am certain some of your readers would willingly give me instruction through your pages.

H. NORTON.

[We are willing to insert letters and diagrams for the assistance of our perplexed correspondents.—Ed. E.M.]

THE EXCHANGE.

Sir,—I am very much pleased to see that you endorse the suggestion of an exchange club, and wish it all success, and trust it will be speedily in operation from personal motives. I think you could occasionally give a sheet of illustration printed from electrotype, taken from finished works furnished by subscribers, to your invaluable Journal.

AN ENTHUSIAST.

[This is a capital suggestion, and we are willing to entertain it.]

Sir,—I shall feel obliged if any of your readers can inform me what power engine it will take to work a pair of Pudding rollers, say, roughing and finishing; and what power engine it will take to work a double-ended puddled ball squeezer to squeeze two balls at the same time. An answer will greatly oblige.

J. THORN.

Tonder Iron and Coal Works, Glamorgan.

Sir,—As several correspondents have of late been asking about the management of steel, I beg to say that I have a little book in my possession which I think may be of some service to brother mechanics. It is the "Management of Steel," by George Ede, Esq., published by William Tweedie, 387, Strand. It concludes forging, hardening, tempering, shrinking, and expansion, also the case hardening of iron, &c.

FRANCIS CLEMENS.

Sir,—Allow me, through the medium of your journal, to return my hearty thanks to Mr. E. J. Mitchell for his kind answer to my request concerning a steam whistle. The drawing he has obliged me with will suit my purpose exactly. I have also to thank you for your kindness in engraving and publishing.

HENRY WILLIAMS.

PARALLEL MOTION.

Sir,—Perhaps the enclosed form of parallel motion is new to some of your readers. It is figured in Professor Willis' "Mechanics." The equation which he deduces is:—

$$\frac{AH}{DE} = \frac{BC_2}{(EF-BO)_2}$$

Taking EF (in the figure) = 8,
DE or FG = 6, and BC = 4

$$\frac{AH}{16} = \frac{16}{16} \therefore AH = 6$$

C. SWANN.

Sir,—Your correspondent David Sloan Thompson says that Watt resorted to the star and planet wheels "to render his engine complete without any other person's production," yet he says that the crank was invented by Watt. I

beg leave to say that the star and planet wheels were adopted for the purpose of increasing the speed of the crank shaft without increasing the number of strokes of the connecting rod. Mr. Thompson is wrong in either the size of the planet wheel or in his statement that the fly-wheel shaft goes 2 to 1, for the planet wheel, according to his drawing the planet wheel, is twice as large as the star wheel, there fore the star wheel would make four revolutions for one of the planet. If the two wheels were the same size (as they usually are) then the star wheel would make two revolutions for one of the planet.

JAMES SHARPE.

SLIDE RULE.

Sir,—Although desirous, as you well know, to assist as far as lies in my power my fellow workmen, in their struggles upward and onward, yet it can scarcely be expected that I could devote sufficient time, or you devote enough space for teaching them the commonest rules of arithmetic. My reply to C. B. M. S. was curt and unsatisfactory, because I considered that a person who could ask a question so well ought to have known better than to ask it at all; but, since it appears from a letter received from another correspondent signed A. B., that there really are some of your readers who do not know why the slide rule cannot perform the function referred to by C. B. M. S., I have no hesitation in explaining the matter.

In the first place, then, in the conversion of a vulgar fraction into a decimal, we continually multiply the numerator of our fraction by a power of ten, the base of our system, by adding cyphers thereto, and by dividing by the denominator we get a new numerator of another fraction, of which the denominator consists of 1, and as many cyphers as we obtain quotient figures from our division.

Here, then, we have three numbers a ways given, viz., the numerator and denominator of the vulgar fraction and the denominator of the decimal fraction, to find the numerator of the latter, and the matter becomes one of the processes of ordinary division.

But, in reversing the process, the question becomes very different, since, if we wish merely to make the decimal into a vulgar fraction, we require no slide rule at all, but merely add unity to the requisite number of cyphers, and the operation is complete, while, to reduce the vulgar fraction to what it was originally (i.e., its lowest terms), we have only two terms given, viz., the numerator and denominator of the decimal to find the numerator and denominator of the vulgar fraction, both of which are unknown, and the only means of obtaining them is to find their greatest common measure (a process often necessitating some fourteen or fifteen separate divisions of one number by another), and then dividing the numerator and denominator of the decimal by the greatest common measure.

In order to show A. B. the stupidity that was wrapped up and neatly folded in the short enquiry of C. B. M. S., I take the simple example given by A. B., converting $\frac{3}{75}$ into $\frac{75}{75}$, he is quite correct in his manipulation; but what has he really done?—simply got $\frac{100}{100}$ instead of $\frac{1}{1}$. Now, if he

knew beforehand that the fraction he was seeking had 4 for denominator, then the reverse method would be equally simple with the primary process, but vulgar fractions do not always have 4 for a denominator, and hence he must proceed thus:—

$$\frac{75}{25} \times \frac{100}{75} = \frac{100}{25} = 4$$

Hence is this perhaps one of the very simplest cases that occurs, no less than four separate divisions are requisite, while, in some cases, they extend to 20 or 30 processes, yet C. B. M. S. enquires for a method of doing all of them by one setting of the slide.

I am sorry that Mr. E. Farnsworth should have been at the trouble of sending an answer to me to a question I never asked; but one which I put on its proper basis a fortnight before his letter appeared. I think your better educated readers who feel a desire to rush into print, should read carefully the subject upon which they intend to write. In the present case, all that has been said upon the matter bears no relation to the question as originally put by T. G. Maugh, viz. (p. 82, Oct. 27):—"What is the method of ascertaining the pressure of a steam boiler can bear by the safety-valve?" I am constrained, from lack of time even now to put this matter in its true light before your readers, but I trust that I may shortly be enabled to do so, as I consider it one of great importance to engineers in general, and more so to those who have to purchase boilers, and work them as a commercial speculation.

With regard to the mere question of the effect of the lever and valve upon the working pressure of a boiler, I trust my last letter upon the subject will remove any difficulty that may come in the way of a juvenile who attempts to comprehend the supposed mystery, but I must say that I was astonished to find one of your correspondents very recently asserting the safety-valve lever to be one of the "second order," an assertion more liable to lead your readers unversed in mathematics astray than all his writing upon the subject would be likely to assist them towards gaining a correct idea of what they are really in search of.

I cannot conclude this paper without calling in question the (to give it its middle denomination) absurd conclusion given vent to by Jno. Tawse. He states that, "In small batteries when you increase the metallic area you increase the electrical power. This can be calculated up to a certain point; but, when you come to hundreds of superficial feet (as in the shape of a ship's sheathing), the power increases in immense ratio." Even with the "unfathomable briny" as a menstruum, this must be taken, as Dr. Marigold says, "Cum grano salis." But, and here lies the matter, is Jno. Tawse, although "he talks like a book," prepared to

levers are caused to work together by a connecting bar H, and a doubled "Hodge's Accumulation," which goes through the end of the connecting bar, and is linked up to the upper lever end. I prefer this elastic stretcher for the saw, because as the saw heats at high speeds, the elastic stretcher takes up the slack, which used to annoy me by causing the saws to break. I, is the saw table, which, of course, may have a shifting stand on it for cutting circles. J, J, are two pins to keep the frame level.

ELECTRICAL APPARATUS.

Sir,—I beg to offer a mite towards your Christmas Extra Number. Probably many of your young beginners in the Electrical Science are not aware that their small store of electrical apparatus may be very much increased by the possession of a "Secondary Battery" by which we have the power of producing very powerful effects, both as regards quantity and intensity, at a very small expense. But it must be understood that which we gain in power we lose in time. But, as time is no object to an amateur, I will proceed to describe the construction of one to be made of sheet-lead only:—

I will premise that the amateur is in possession of four or five smallest size Daniell's batteries. If not, three small-sized Bunsen's or Smee's will do.

Procure two pieces of sheet-lead (the thickness is of no importance) about 2 feet long and 6 inches wide; let these be separated by a sheet of a non-conducting material, and then roll the lot lightly together, taking care that each sheet of lead is thoroughly separated from each other; cut a strip of lead from each sheet to serve as a connection to the Daniell's or any other primary battery. Having done this, place the roll of lead into a jar, and fill up with sulphuric acid and water—1 part acid and 7 water. Now have the primary battery in readiness, and connect one sheet of lead (by the strip cut off) to one pole of the primary battery, and one to the other pole. After the first connection to the primary battery has been made, the same sheet of lead must be connected to same pole whenever the operation is commenced again.

Having now connected the secondary battery to the primary battery let the current work for half an hour (and here is where we loose the time, but we shall gain much in power, as will be seen); at the expiration of this time disconnect the primary from the secondary. Now, to show the power that has been gained, try to burn a piece of iron wire with the primary battery, and you will find that it cannot be done. Now try the secondary battery, you will find that we have increased the quantity, at least, three times without any more expense (for the lead is not acted on in the secondary battery). The power of the secondary battery will decline gradually, but it must be understood that another secondary battery may be connected to the primary battery during the time we were using the one that was first charged. I have only to add that twenty or three secondary batteries, properly connected, will produce the voltaic arc of light, and no expense but the primary battery. I need not suggest how three or four secondary batteries, after being charged, may be connected for intensity, and used for charging other secondary batteries. If this trifling meets your approval, I shall have much pleasure in sending you a description of one even more powerful than this, and which may be charged from one primary battery and a primary coil of wire.

ANON.

MICROMETER AND EQUATORIAL MOUNTINGS.

Sir,—It would be impossible to give an intelligible description of the equatorial mounting of a large reflecting telescope without numerous diagrams, which could only interest a very limited number of your readers. But if T. W. B. would make a proper application to the Council of the Royal Astronomical Society, he would probably be permitted to inspect Mr. Lassell's photograph and description of his mountings, at their rooms at Somerset House, where he would also see other models, and might obtain information which would be very valuable to him.

With regard to what he calls the "double position micrometer" (by which he evidently means the double-image position micrometer) the following directions will enable him to employ it. I assume, of course, that the telescope with which he is using it is equatorially mounted. Supposing that he has the instruments before him, he will find it to consist of a position circle, and an eye-piece containing four pieces, of which the third (from the eye end) is bisected, and one of its halves movable by a micrometer screw. When the two segments of this lens are accurately in the position which they occupied before the lens was cut, the eye-piece will transmit but a single image of a star, the micrometer head should then read 0, as should the little scale on the pointer, which shows the number of who a revolutions made by the screw (This last adjustment is made by the maker, the first is perfected by twisting the micrometer head round on the screw, when there is but one image visible). Now, then, let T. W. B. put in the eye-tube with the wire stretched across it, which will be supplied with the instrument, direct the telescope to a star, separate the images, and turn this eye-tube until the wire bisects these images. Then set the vernier to .00° on the position circle and keeping it there, turn the entire micrometer, circle and all, round in the eye tube of the telescope until the star continues bisected by the wire when the telescope is moved up and down upon the declination axis. The zero of the position circle is now in adjustment.

To find the value of the micrometer screw, turn the micrometer by means of the milled head, until the vernier of the position circle reads 90° separate the images of a star any number of revolutions—say 10; and having securely clamped the telescope, note the interval of time between the passage of these two images over the wire. 1 h is in seconds of time $\times 15 \times \cosine$ of the star's declination will give the value required in seconds of arc; whence the value of one revolution of the screw, or one division of the

micrometer head may be immediately obtained by simple division.

To measure the position of a double star: separate the images, and turn the position circle by means of the milled head until the four stars are in a straight line—the vernier will show the angle of position.

To ascertain the distance, calling the stars A and B: Place A upon B, and B upon A alternately. The mean of the readings will give the distance.

A FELLOW OF THE ROYAL ASTRONOMICAL SOCIETY.

OUR SUBSCRIBERS' NOTES AND QUERIES.

THE STEREOSCOPE.—Will any reader inform me the best method of preparing pictures for the stereoscope, and for colouring and varnishing them?—AMATEUR.

CIRCULAR SAWS.—Will any reader kindly inform me the address of any maker of small circular saws about 8 inches in diameter, the teeth not like joiner's saws, but about half an inch long—say two teeth to an inch, and project 3-16ths?—A JOINER.

ADDRESS WANTED.—Can any subscriber inform me the address of M. RUMKORT, a philosophical instrument maker in Paris?—G. G. M.

WHEELS.—Can any reader tell me the best mode of making level wheels?—JOHN MILAN.

DOUBLE TREAD WORM.—Can any reader tell me how to draw a double tread worm?—ONE IN A FIX.

SOFTENING IVORY.—Can any reader inform me of a method of softening ivory, so that designs can be impressed upon it? I have some recollection of a description of the process being given in one of the scientific journals, but the name has quite escaped my memory. I shall feel very grateful for any information on the subject.

—JOHN MCMURRAY.

ELECTRO MAGNETIC ENGINE.—I am about to construct an electro magnetic engine, to be worked by two magnets, with fly wheel and crank. I intend placing the magnets opposite each other, which will attract alternately a piece of iron connected to a crank, and thus propel the fly-wheel. If any reader could assist me with any suggestions, they will be thankfully received by—E. MADDOCK.

PAINT AND STEAM POWER.—Can any correspondent tell me how to make a black paint suitable for the smoke box, chimney, &c., of a portable steam engine? It must be cheap and must be able to stand heat. Also, if a steam engine, say 10-horse power, be put to do the work of a 5 horse power engine, should it require any more fuel except so much as the increased weight of engine would require to move it? It seems to me that a certain amount of heat should give a certain amount of power, but I find that in two engines of the same construction the 10 horse-power requires two or three hundred of coals per diem more than the smaller one, and is doing no more work. How is this to be accounted for?—F. H. T.

ALARM.—Will some correspondent inform me how I can construct an alarm calculated to awaken at any hour without clock or watch being used. I am aware they are constructed to act with sand or water, but I don't know the way to do it?—J. M. K.

Can any reader inform me of a rule to find the quantity of water evaporated per hour to feed an engine with steam; cylinder diameter 22 inches, 4 feet strokes, speed of piston 330 feet per minute, boiler pressure 50 lbs. average pressure in the cylinder, 15 lbs. per square inch?—W. H.

WATER POWER.—Perhaps some reader will tell me the best method of obtaining a small working power from a town water supply, say a common water-wheel or turbine wheel?—SCOTCH MECHANIC.

BATTERY.—Can any of your readers inform me how to make a thermal electric battery?—CHIPS.

HYDRAULIC.—Can any reader inform me how much more water will be forced through a pipe (say 1-inch in diameter) giving two, three, or four times the pressure? For example, I get, say, 50 gallons a minute from a body of water 10 feet high, how much should I get with a pressure of 20 feet, 30 feet, and 40 feet high?—GREEN.

GUN BARRELS.—Can any reader assist me with a recipe for boring gun barrels so as to bring the twist up?—SPORTSMAN.

FURNACE.—I am a smith, and am anxious to make a trial at the castings in connection with my work. Will any reader assist me to the best method upon which I can construct a small furnace cheaply?—GEORGE NEILSON.

GAS HOLDER.—Can any reader tell me the weight of a gas holder nine feet diameter, by thirteen in depth, made from plate 5-16ths thick, allowing 1-16th for waste in making, which would leave 4-16th thick.—BETA.

INDIA RUBBER CLACKS.—Can any reader inform me where I can purchase the India-rubber clacks for pumps, pumps, and what about the price.—T. H. O. E.

TELEGRAPHIC INSTRUMENTS.—In No. 28, Vol. II, you gave an article on our "Telegraphic Instruments." I embrace the opportunity to gain a little insight into them. A few days ago I had a look into what is called a single instrument. It worked with a hand like a clock. Now, what I want to know is, how the electric current is conveyed through the instrument and made to act with such precision in connection with the hand?—CIMA.

PHOTOGRAPHY.—Can any reader oblige me with information as to the best artificial light for taking photographs during the winter evenings, and the different chemicals used for working by sunlight?—LEWIS.

Can any reader inform me how to preserve mathematical instruments from rust without using oil or grease?—R. J. T.

I have an improved plan for a screw propeller for propelling ships. Will any correspondent inform me the best way to get a spring to drive a model from four to five feet long?—A. GOODWILL.

ELECTRICAL MAGIC PICTURE.—Could Mr. Tonkes or any of your electrical correspondents inform me how to make the electrical magic picture and the inclined plane?—J. WOOD.

REPLIES TO QUERIES.

—OVAL CHUCK.—In reply to G. H. D. in No. 39, I feel hardly competent to instruct him, for I am but a mere amateur. If, like myself, he has constructed portions of his turning apparatus, as I judge he has, I might afford a hint or two; but if he has always depended upon his lathe maker for alterations or additional mechanism, or is not acquainted with the principle of action and usual construction of oval chucks, then I should have to enter into such lengthened details as would occupy too much of the valuable space of THE ENGLISH MECHANIC. I would, however, recommend G. H. D. to apply to Messrs. Holtzapfel, first, at their establishment in Cockspur-street, Charing-cross, where under the name of a turning lesson at two shillings per hour, he will feast his eyes on the perfections of endless apparatus, and be attended by superior and gentlemanly workmen to explain and simplify the same, and answer every question he can put to them. Afterwards let him go to the manufactory of the firm in Long-acre, where they will instruct him on the same easy terms in the mysteries of filing, planing, surface testing, screw turning, boring, slotting, hammer hardening, polishing, curling, &c. If, however, G. H. D. should prefer my inferior suggestions, let him say whether his mandril has a hollow or a projecting screw for fixing its chucks; height of its centre from the upper part of the lathe bed, and the diameter and amount of precision required in his oval work.—CHANCEIRO.

FRET SAW.—On the 32nd ult. Wheelwright wished information respecting a fret saw capable of cutting in felloes and centerings; in answer to him I am about to erect one designed by W. Sketchley, Great George street, Weymouth, which I am of opinion will suit his purpose admirably. The table can be adjusted to any angle required, and is also free to turn any size plank on it at any radius. If Wheelwright will write or call, I shall be happy to give him any information. I have no interest in the saw being advertised.—W. J. DAW.

21, Clarendon-road, Notting-hill.

IVORY STAIN.—T. Simpson. Stain may be imparted to ivory in the following manner:—Blue.—Immerse in a strong solution of sulphate of copper until it is the tint required. Black.—Soak in strong solution of logwood, and then steep in solution of acetate of iron. Green.—Boil in solution of verdigris until dark enough. Red.—Steep in red ink until sufficiently stained. Scarlet.—Use lac-dye instead of preceding. Yellow.—Impregnate with nitro-hydro-chloride of tin, then digest with heat in a solution of fustic.—T. ALLEN.

PLANET MOTION.—I beg leave to inform David Sloan Thompson, through the medium of your valuable periodical, that in his description of Watt's sun and planet motion, he made a slight mistake in showing a bar connecting the two wheels. In the original motion invented by Watt, the teeth of the wheels simply worked into each other without any connection.—WILLIAM H. THOMPSON.

CASE HARDENING IRON.—Use bichromate of potash, instead of the prussiate, with the pith of ram's horns, (some use hoof-parings), cut in small pieces, and laid on the hot surface to adhere, sprinkle on the bichromate in powder, while turning the iron round with the tongs. The best file in the world won't touch it.

SOFT SOLDERING.—Copper, pewter, tin, lead, and brass, can be soldered with spirits of salts (which has been "killed" with zinc), for a flux. This will solder anything but zinc itself, for which free acid must be used. The killed spirits may remain open to the air for weeks without deterioration.—G. E. CHICK.

Brittle asks, in your excellent publication (Dec. 15th), why the glass tube of a water gauge, or a steam-gauge breaks some hours after it has been cleaned with a wire, and when quite cold? I beg to say in reply that it is because the wire sometimes scratches the "skin" of the glass, and the fracture thus commenced imperceptibly extends itself until the tube finally breaks. The skin of glass is a thin pellicle which lines or covers its surface. If the glass be carefully annealed, this skin becomes part and parcel of it, and is no longer liable to the casualty named. Under favourable circumstances the skin of glass may be seen detached, and is then found to be an extremely fine substance like goldbeater's skin. German glass is, as a rule, better adapted for tubes, such as those named by Brittle than that of English manufacture.—JOSEPH NEWTON.

WATER IN PIPES.—In reply to Johannes' question, I beg leave to say that the cause of the water is that the pipes are not laid level, and the best cure is a dry meter, but should this be to much expense, he must find where the water lays and insert a piece of pipe in such a manner that the water will drain into it. Will any of your kind readers inform me how to construct a pair of opera glasses that when extended to their greatest length will be from six to ten inches in length. The size of glasses, price, and where to be obtained in London; also, an explanation of the model of the engines of the minotaur alluded to in No. 39 of your valuable paper?—A. YALDIA.

LENSES.—I beg to inform Regius that he can get lenses for a cheap microscope from J. Cox, 22, Skinner street, Snow-hill, London. Mr. Cox will forward a catalogue of lenses to any one for 2 stamps. I can fully confirm all that a Fellow of the Royal Astronomical Society said about non-achromatic single lens eye-piece telescopes. I made one myself a few years ago; I was so disgusted with its performance that I only looked through it once in that state, I then fitted an eye-piece to it (composed of two plane convex lenses) belonging to my microscope, it then showed Jupiter's moons very well, but it was very awkward to use without a stand, being about 6 feet long. I then thought about making a stand for it but found that it would cost more money to make one to carry the thing than it was worth. I then made a 2½ achromatic one which is all an amateur can desire, it will show Polaris as times. It is unnecessary for me to inform your readers how to construct a telescope, that having been done. By the annexed price list they may see that they can make for themselves for a

little more money an achromatic telescope, of one-half the length, double the power, and with good definition, which will always be a source of pleasure to them instead of disgust. The above is the experience of (OLD) CHARLIE. From Slug's list, 244, Shetford-street, Manchester. Achromatic glasses fitted in cells—

1½ diameter	34 in. focus	5s.
1 1-16 "	30 to 35 "	9s.
2 "	36 to 40 "	12s.

Single lenses for eye pieces. 1, 1½ in. each, 1s.

OCULOS.—The increase would occur in all metals that oxidise in the fire. The copper may have absorbed a little carbon, but far more oxygen.—G.

GULLIVER.—Wax and tallow will answer, when the cells are new, made warm, and applied on the inside. You can do no good with cells when the acid has got in.—T.

Allow me in reply to A Student, to describe the following very simple, yet efficient galvanometer:—

Let the point of a fine needle a, project about a ½ of an inch from the centre of a board b, about 6 inches square. Let about 3 yards of No. 35 silk covered copper wire be coiled around any convenient form, so as to produce a quadrangle c, about 3 inches long by 4 high, care being taken to leave the two extremities of the wire free. Let stability be given to the quadrangle by tying its four corners. The coil must then be fixed on the centre of the board b, allowing the needle to pass through the middle. Two small mercury cups d, d, are then to be screwed on the board in electrical communication with the free ends of the coil c. A circular card, corresponding in size to the inner dimensions of the coil, and divided into 360 equal parts, is then to be passed over the under portion of the coil allowing the needle to protrude through the exact centre. Lastly, a well magnetised needle e, provided with a delicate pivot, is to be nicely poised on the point a. The show and prove (which is of still greater import) that any such law of electrical manifestation exists? Now, more than myself would hail with delight any such proof forthcoming from his pen, and there will be few readier than I to reduce him to his proper status if he has ventured to give publicity to such a statement contravening all our pre-received ideas and laws of electrical excitation without the necessary proofs founded, at least, upon actual experiment. WM. TONKES.

FRET SAW.—According to promise, I send a sketch of the fret saw, and seeing another inquiry from a Wheelwright, as to whether it will cut felloes, &c.; I have to say that by driving it by a flywheel as some heavy lathes are turned, by a man at a crank handle, hard wood of considerable thickness may be cut. I have with the slow motion, and sweep saw cut four inch hard wood, so your correspondent may judge accordingly.—THOS. E. MERRITT.

A, is the frame, fitting between the beds of the lathe B, the fore part of which is shown removed, to allow the levers C, C, to be understood; C, C, are two brass cylindrical rods, the lower end of the upper rod being undercut, as in fig. 2. The upper end of this lower rod is also undercut, and a saw kerf is made at A (fig. 2), for the purpose of fixing the fret saw tightly in the ends of the rods; the ends of the fret saw being thrust into a drop of melted solder, which gives a hold for the saw in the saw kerf. The rods C, C, slide up and down through the frame A, and are driven by levers E, E, which are pivoted to the standard D, D. An extension of the lower lever is connected to the driving chuck F, by a driving rod G. The aforesaid

whole apparatus, with the exception of the cups d, d, ought to be covered with a glass bell. If the coil be now brought parallel to the needle and communication be made with any source of electricity, by means of the cups d, d, the needle will be deflected a certain number of degrees; and *ceteris paribus*, the stronger the current, the greater will be the deflections. Should greater delicacy be thought desirable, the magnetic needle ought to be suspended by a single filament of silk, instead of being poised on a pivot.

PHOTOGRAPHY.—The Bath.—In answer to a correspondent's inquiry, E. J. Atcherley, in your No. for the 22nd ult. I would recommend him to filter his bath through cotton wool, which should be first moistened with a little alcohol, and then pressed pretty tight into the neck of the funnel and then draw through from the bottom with the mouth so as to get a passage, and do not use kaolin, as it is not required. It will generally take 8 to 12 hours to pass through, and when once in use will keep so for months. I have met troubles the same as described, and found the above the remedy in my case; but he does not say whether his bath is made up with anything but silver and water. It may not answer in his case, at any rate, it is worth a trial, and being a practical photographer of 9 years, I shall be happy to help your correspondent if it does not answer, and he will send further particulars through your paper.—HARRY MORTON.

WOOD STAINING.—Parisian may imitate ebony by staining his wood, in the first place, with a hot saturated solution of logwood, containing a little alum; and, when dry, brushing it over with common writing ink. I made a very successful imitation of ebony the week before last by this process, with pear-tree wood. I cannot help him about gilding and marbling.—AN AMATEUR TURNER.

LENSES.—I may answer Gladiateur's enquiry about lenses by saying that an achromatic object glass only, will bear anything approaching to powers of 300 or 600; and that he will scarcely obtain one under 60 or 70 guineas to perform decently with this last amount of amplification.—AN AMATEUR TURNER.

TELEGRAPH CABLES, &c.—In reply to question of Veritas: 2386, 24th September, 1863, and 2015, August 4th, 1865, not sealed yet.—T. G. M.

Gas.—Johannes asks the cause and remedy for water deposited in gas pipes; as it would require a long article to explain it, I recommend him to buy Mason's "Gas Fitter's Guide," price 1s.; published by Mr. Hill, 54, Murray-street, City Road.—JAMES SMITH.

ANSWERS AND NOTICES TO CORRESPONDENTS AND READERS.

ALL letters intended for the Editor should be addressed to 75, Fleet-street.

Letters applying for information to be furnished by post cannot be attended to.

Correspondents are requested to keep copies of their drawings and manuscripts, as the Editor cannot undertake to return such as may be rejected.

W. E., (Design for Boiler).—We have to apologise for delay in answering. Do you think you could utilise all the heat developed? We doubt it, though this may look to you a funny statement. We are of opinion that an undue strain would be exerted on the boiler plates at section c, d, provided your drawing is correct, for according to it one can see that at certain temperatures, that is, the maximum of variations, there would be a strong tendency to getting out of shape. If printing is not to be added, but we are inclined to think the drawing is in fault; and, if so, then we think your boiler will be able to get up steam very rapidly. Your "alteration" is a very simple one, and we are inclined to think it new.

J. GORMAN.—Out of earlier; 39 cwt. is the weight.

P. STUBBS.—You have not complied with the specification, and the award, under the circumstances is perfectly correct. What you say is simply matter of opinion, not of action.

N. GREGORY.—It is now a very common practice. They are let out at £1 and 3s. a month.

P. FOXE.—His address is at the Mint, Tower-hill. A letter will be sure to reach him.

M. PARKES.—You don't believe in the effect of friction! We can't help that. An author may write you a book, but he cannot make you the brains to understand. Take a bit of steel, hold it on the burnisher of your polishing lathe for a while, whilst you work the treadle briskly; you will very soon find out what friction will do for your hand.

A. ROES.—Advertise in our columns. We cannot insert your communication, as it is an advertisement.

NEMO.—Messrs. Tennant, of Glasgow, and Newcastle, distil their sulphuric acid in patina stills to separate a little lead from it dissolved during the process of manufacture. To detect sulphuric acid in vinegar, add a little solution of nitrate of baryta. A white powder of sulphate of baryta will be precipitated. This, we believe, is a common test.

L. HOMPHERIES.—Holman is the patentee, and has often exhibited.

E. DALRYMPLE.—The register you require is published at the Patent Office, and that up to 1853 is charged 10s. That for the year following is also to be had at about 2s. or 4s. Stamps to Mr. Woodcroft will fetch them for you.

F. GUNZ.—The English engine used for the Mont Cenis line is that of Mr. Kell; its peculiarity is the mid-rail, to gain adhesion. It is a success.

GORDON NISBON.—The number of the specification is the current year.

C. LUCK.—Thanks, but too late; we may perhaps find room in a future number.

W. JARDINE.—Perhaps we may treat on the subject in a future number, several thousand copies were excellently printed, every letter clear.

M. V. HAZO.—A good idea, submit it to some practical firm.

CINA.—Under consideration.

ROTARY ENGINE.—Read the works published by Spon, Bickersbury, Wren, High Holborn, and Virtue, Amen-corner, Paternoster row.

TURBINE.—Write to Mr. Middleton, at Loman-street, Southwark, as to cost. Other boilers can, of course, be made, but they must be of an entirely different construction.

A. B.—Letter forwarded to Mr. Tonkes.

*** We have to ask our correspondents to sign their communications that they may be able to recognise the answer. "A Subscriber" is no signature—we have them by the thousand; the same with "Well-Wisher," &c.

SCIENTIFIC NOTES.

The Royal Society of Fine Arts of Gand has determined upon a grand international exhibition of photographic objects. It will be under the joint patronage of the Belgian Government and the town. Communications should be addressed to M. de Wylder, a Gand.

C. Schroeder Van der Kolk, son of the great anatomist, has just published a work entitled, "Soul and Body" (Seele und Leib), in which he endeavours to prove that what is called soul is simply the manifestation of brain, just as digestion is the function of stomach. He says, memory, imagination, reason, and even volition, are but the result of physical actions, or electro-molecular, excited by the operation of preception—the contact with the outer world.

M. I. Nicles has just announced a new re-action, by which cane-sugar may be distinguished from glucose. If cane-sugar be enclosed in a tube with anhydrous or hydrated bichloride of carbon, and maintained for some time at a temperature of 212° Fahr, it gradually alters in colour; first becomes slightly brown, and ultimately becomes tany in appearance and consistence. Under similar circumstances glucose does not change colour.

In the course of the controversy upon the subject of London milk, which took place at the last meeting of the Society of Arts, Dr. Voelcker, who may be regarded as our best authority, stated that London milk is decidedly inferior to that from the country. In London the cows have more food rich in fatty matter, which yields a milk richer in butter than that of the country. However, the article sold to the consumer is very different, one-third or one half water, after the cream is taken off. For his own sake, he was sorry to say he did not believe in the alleged absence of adulteration in London milk, and he had analyzed many specimens. The specific gravity test is, as a rule, a good one for the protection of the consumer.

CHLORINE WATER.—It has long been known that in chlorine water exposed to air and light hydrochloric acid is formed. Milon has lately shown that some hypochlorous acid is also produced. More recently Barreswill has proved the formation of some perchloric acid under the same circumstances, which observation has been confirmed by Schmitt. —*L'Institute*, 1865, p. 231.

PREPARATION OF IODIDE OF POTASSIUM.—Fuchs places 100 parts of iodine in a porcelain dish with 260 parts of distilled water, and adds thereto 75 parts of pure carbonate of potash and 30 parts of iron filings. The mixture is well stirred together, and allowed to stand. The action proceeds slowly by itself, but hastened by the application of heat. When the evolution of carbonic acid has ceased, the mixture is evaporated to dryness with continual stirring. It is better to allow the mixture to stand for some time in a lukewarm drying oven until all the iron is peroxidised, and then evaporate to dryness. The dried mass is then placed in an iron vessel and heated to a dull redness. The residue is then extracted with the smallest quantity of distilled water; the solution, which has usually a alkaline re-action, is then saturated with hydriodic acid, and set aside to crystallise.—*Dingler's Polytech. Journal*, Bd. 177, s. 251.

Dr. Joule records a very sensible action of the aurora borealis upon the magnetic needle. The needle becomes violently agitated, and undergoes in the course of a minute thirty-six changes of deviation, varying from 10° to 160°. The cause of the movement seems to be instantaneous in its action. When the aurora appears to the west of the magnetic north, the needle is deflected toward the east.

The Rev. Mr. Bowditch's apparatus for improving gaslight is attracting attention. Dr. Grace Calvert mentioned it in one of his Cantor lectures last session, and it has been tried with satisfactory

results by experimentalists in different parts of the country. Briefly, the apparatus may be described as a tight metallic vessel, containing oil, or naphthalin, or whatever hydrocarbon may be used. The gas enters by one opening, passes across the surface of the liquid, takes up its vapour, and escapes by another opening to feed the burner. As the flame is placed below the vessel or holder, the contents are vaporised; hence the passing gas finds material already prepared for enriching the light. The amount of improvement is remarkable; for, with the addition of about thirty grains only of naphthalin vapour to one foot of gas, the light is increased seven or eight times. With oil, the result is lower, not exceeding from four to five times; but even this is an important gain. Mr. Bowditch has made numerous experiments at his residence at Wakefield, and among the practical conclusions which he has worked out, the following may be selected as highly satisfactory; namely, that with his apparatus, one gallon of oil worth 2s. will produce with 1,000 feet of coal-gas such as is used in London, more than would be given by 4,000 feet of gas; the cost being in the one case 6s. 6d., in the other 18s.

ARTIFICIAL IVORY.—The *Mechanics' Magazine* says that the process by which the most successful imitation of natural ivory is obtained appears to consist in dissolving either india-rubber or gutta-percha in chloroform, passing chlorine through the solution until it has acquired a light yellow tint, next washing well with alcohol, then adding, in fine powder, either sulphate of baryta, sulphate of lime, sulphate of lead, alumina, or chalk, in quantity proportioned to the desired density and tint, kneading well, and finally subjecting to heavy pressure. A very tough product, capable of taking a very high polish, is obtainable in this way.

PRINTING IN THE DARK.—A correspondent sends us (*Photographic News*) a curious illustration of printing in the dark. A piece of sensitive paper being contact with a printed bill, in the darkness, presents a perfect transcript of the bill, the white portion of the printed bill being on sensitive paper a pale brown, and the letters a yellowish white. Our correspondent says:—"The enclosed is a piece of paper sensitised on a 20-grain gelatine bath, on Saturday. The same night it and some more was rolled up by the boy in four thicknesses of paper (the innermost one being a common printed bill), and put in the bottom of a counter drawer, and covered by a large book, thereby keeping all light and nearly all air from it, as I expected; and, this morning, when opened out, the piece with sensitive side next to the bill received the impression which you see."

ADVANCE IN THE PRICES OF PHOTOGRAPHIC APPARATUS.—We understand that there is a possibility of an advance in the prices of photographic apparatus imminent. The cabinet-makers engaged on this work have held a meeting, and resolved on memorialising employers for an advance of 10 per cent. on the present rate of wages. This will be the preliminary, we believe, to a strike, in case the request be not complied with. We can readily sympathise with the plea upon which this effort is made. It is alleged that the necessities of life have, of late, increased much in price. This is undoubtedly true, and will press hardly on all whose income is a fixed sum, determined at a time when money was more valuable and food cheaper. We should deprecate a strike, however, for the sake of the workmen themselves. They already receive, we believe, a higher rate of wages than cabinet-makers not connected with photography, and a strike would probably bring a number of other men into this branch, who would require a little training, it is true, but who would eventually, probably, by increased competition, reduce the wages below the present standard. We cannot pretend to advise definitely in the matter. We believe the employers will consider this question fairly, and should they see the propriety of complying with the demand, photographers, we presume, must be content to pay a slightly advanced price for cameras, &c.

PHOTOGRAPHY AND THE PRINTING PRESS.—The *Pall Mall Gazette* has the following paragraph on some new process in which photography is concerned, but how does not seem clear:—"Messrs. Sampson, Low and Son's illustrated edition of 'the Pleasures of Memory' is remarkable as introducing specimens of a new method of pictorial art. They are produced without the aid of an engraver. The drawing is made with an etching needle, or any suitable point, upon a glass plate spread with collodion. It is then photographed upon a prepared surface of wax, and from this surface an electrotpe is obtained in relief which is printed with the type."

If this process could be carried out successfully it would give us an important advantage: the artist's own work would be preserved; whereas, even in good wood engravings, it is always marred more or less. We do not know whether in the book before us we have the first adventures in the process, but if so, the results are by no means discouraging. Some of the illustrations are poor, but others—notably, the figures on pages twelve and forty, and a striking bit of landscape on page twenty-eight—show that the method has distinct and peculiar advantages."

REVIEWS.

Lives of Boulton and Watt. Principally from the original Soho MSS. Comprising also a History of the Invention and Introduction of the Steam Engine, By SAMUEL SMILES. London: Murray, 1865.

To few can a history of these two men be more interesting than to the readers of this journal of British Mechanics; and any work claiming to be a history of them deserves attention at our hands. Mr. Smiles has grown quite a bookmaker, and his name is now as "familiar in our mouths as household words." As to the correctness of his books—that is quite another affair. He was not particularly successful over George Stephenson; concerning that of Watt, we cannot see that it was at all wanted. "Lives" of Watt are as plentiful as blackberries in summer, and that by Mr. Muirhead—the intimate friend of Watt, and Boulton's son-in-law—is so admirable that we scarce can mention it in the same line with Mr. Smiles' effort. Still, as a book, the one before us is very readable; and the reviews of it we have noticed in the press could not well have been more favourable to its author if he had penned them himself. Comparing the two works, we would not only sooner have that by Mr. Muirhead, but we think Mr. Smiles is greatly indebted to that gentleman for much of his material. We need say but little concerning Watt; every schoolboy is acquainted with his life, and every cyclopædia of any pretensions has a fair memoir under the letter W, or the article on the steam engine, to which, by the way, Mr. Smiles devotes much room in the early part of the "Life." The commencement of the book is encouraging:—"When Matthew Boulton entered into partnership with James Watt, he gave up the ornolu business, in which he had before been principally engaged. He had been accustomed to supply George the Third with articles of this manufacture, but ceased to wait upon the King for orders after embarking in his new enterprise. Some time after, he appeared at the Royal levee, and was at once recognised by the King. 'Ha! Boulton,' said he, 'it is long time since we have seen you at Court. Pray, what business are you now engaged in?' 'I am engaged, your Majesty, in the production of a commodity which is the desire of kings.' 'And what is that? what is that?' asked the King. 'Power, your Majesty,' replied Boulton, who proceeded to give a description of the great uses to which the steam-engine was capable of being applied."

And then we make the acquaintance of Hero, and a lot of excellent material given years ago, by Mr. Muirhead, with this difference, that we are reminded now and gain how the "black-looking stuff" grew into the "three black crowns." We object to Boulton taking precedence of Watt, for though he was a man of energy, mechanical knowledge, and ability, he is not entitled to a prominent place amongst engineers, and he never claimed it. It generally remains for ancestry or folks desirous of making a stir to set up such claims; and we have ample proof of this in connection with George Stephenson. That Boulton was a credit to Birmingham is gladly acknowledged by all who know anything about him, and that he was a sagacious man is evidenced by the readiness with which he recognised the merits of Watt's improvement on the steam engine. Furthermore, he staked heavily on it while its success was yet a thing to be achieved. It may safely be stated that no inventor ever met with a more energetic and liberal capitalist for a partner than Watt met in Boulton. In character the pair presented a strange contrast. Watt was a cautious, "inexpensive" man as to business concerns; Boulton was bold, sanguine, rash; Watt was timid, Boulton afraid of nothing. It may be noted here that Mr. Smiles has the credit of bringing before the reader the ill-feeling that at one time existed between the two partners. That ill-feeling, however, was but transient, and vanished with the success of the steam engine. It appears that the quarrel between the pair arose through Watt's refusal to join Boulton in a scheme for "raising the wind." "When I reflect," Boulton wrote to a London friend, "on Watt's situation in 1772 and

my own at that time, and compare them with his and mine now, I think I owe him little." "I some time ago gave him a security of all my two-thirds, after paying off (the bankers), from which you may judge how little reason he has to complain. He talks of his duty to his wife and children; by the same rule I ought not to neglect mine. His wife's fortune joined to his own did not amount to sixpence; my wife brought me, in money and lands, £28,000. I advanced him all he wanted, without a security; but in return he is not content with an ample security for advancing nothing at all but what he derived from his connection with me." This was ungenerous—showed too much consideration for the "capitalist," but as we have said, it blew over; and Mr. Smiles is entitled to the credit due to resuscitating the unpleasantness. That Mr. Boulton was a just man is not to be doubted; and he did ample justice to the man who was more than partner, who was a firm friend; and the two lived affectionately together until the great divider stepped in to separate them. Though Watt was devoted heart and soul to science, he yet had moments of other "inspiration," concerning one of which a friend says it was an eminently "Scotch inspiration"—the bawbee. Writing to Boulton in 1779, he says:—

"Hallelujah! Hallelujah!
We have concluded with Hawkesbury.
£217 from Lady-day last,—
£276 5s. for time past; £157 on account.
We make them a present of 100 guineas.
Peace and good fellowship on earth:—
Perrins and Evans to be dismissed.
Three more engines wanted in Cornwall:
Dudley repentant and amendant.
"Yours rejoicing,
"James Watt."

The following is not bad:—"In the case of an engine supplied to F. Scott and Co., to work a hammer, it appears that instead of applying it to the hammer only, they applied it also to blow the bellows. The consequence was that it worked both badly. They had also increased the weight of the hammer." Watt of course heard of this, and wrote to say that the "defect" might easily have been foreseen, and that "the only adequate remedy is to have another engine to blow the bellows. It is impossible that a regular blast can be had whilst the engine works the hammer and bellows, without a regulating belly as big as a church!" "They have been for having a pocket Bible in large print!" Again, certain plans of the Handsworth parish church (which was about to be enlarged) were sent to Watt, when he was a big man, residing at Heathfield, for his approval. After looking them over, he remarked, "If these plans be carried out, preaching at Handsworth will be like squirting the word of God through a keyhole;" a remark which says more for his style of expression than for his taste.

On the whole, we like and we don't like Mr. Smiles' book. We like it for much of the matter concerning the two men; we don't like it, because all that can be said has already been well said by Mr. Muirhead. In fact, the book was not wanted; and we have no genuine affection for anything superfluous, however handsomely got up. Those who have not got a cyclopædia, or have not Muirhead's book by them, and feel interested in the subject, will probably purchase Mr. Smiles' edition.

INCREASE OF WAGES.—On the 14th inst., Mr. Sheriff Figgins and his son, Mr. James Figgins, of Ray-street, Farringdon-road, formerly of West-street, City, letter foundry, had an interview with their dressers, and intimated that they would give them an advance of 3s. per week upon their wages, which advance should date from Saturday, the 30th ult. They further proposed some other liberal alterations, which cannot fail to give the greatest satisfaction.

DEATH OF AN EMINENT MINING ENGINEER.—Intelligence reached Newcastle-on-Tyne on Tuesday evening that Mr. Nicholas Wood, of Hetton Hall, the eminent mining engineer, was dead. Mr. Wood, who was in the 72nd year of his age, had gone to London to consult his medical adviser, and died there on Tuesday. Mr. Wood had been connected with extensive mining operations in Northumberland and Durham fully half a century. He was associated with George Stephenson at Killingworth Colliery, and had for years been a great authority upon all subjects relating to mining engineering in every part of the kingdom. Mr. Wood was a large coal owner in the county of Durham, and his name is associated with the late Mr. John Buddle and other great authorities in mining engineering, and with George Stephenson in the early history of railways.

EXTRACT OF COGNAC AND OF WINE.

This is a mixture of several ethers of the ethylic series, but of which the special odour is that of pelargonic ether. The essences may be prepared in two ways; the first gives nearly pure pelargonic ether, the other mixture is a very variable composition and apparently inferior in quality. By the first method, pelargonic acid is obtained by treating oil of rue by nitric acid; to etherise pelargonic acid, dissolve it in concentrated alcohol, and pass into the mixture a current of dry hydrochloric acid; the pelargonic ether rises to the surface as it forms. By the second method, a fatty body is treated by nitric acid, and fixed fatty acids are produced, such as adipic, pimelic, lauric, succinic, &c., and also volatile acids, which may be distilled, and of which the chief are butyric, valeric, capric, caproic, caprylic, cetyl, and pelargonic. This is the mixture which is to be etherised. Alcohol is sometimes scented with the product obtained by etherising cetic acid, extracted from cocoa-nut oil. To obtain this acid, saponify cocoa-nut oil by potash, decompose the soap by hydrochloric acid, dissolve the acid thus obtained in alcohol, and pass into it a current of dry hydrochloric acid; a yellowish liquid will be the result; wash it with water and alkaline water, when pure cetic ether will remain, which mix with ten times its volume of alcohol. The richness of commercial essences in pure essences may be ascertained by distillation; alcohol boils between 80° and 85°, and the essences remain as residue. Artificial essences are not generally used in perfumery, expecting essence of mirbane; but other agreeably-scented essences will very probably be some day used, carefully combined and considerably diluted. As found in commerce, they have an odour which is far from agreeable, and they, moreover, have an injurious effect on the animal economy when inhaled in sufficient quantity; they must then, if used, be used sparingly.—*Des Odeurs, des Parfums, et des Cosmétiques.*

USE OF ULTRAMARINE IN REFINED SUGAR.—M. Monier writes to *Les Mondes* that the use of indigo, referred to in the *Chemical News* some time ago, has long been given up, and ultramarine is now employed. For a boiling of 800 loaves, weighing on the average 10 kilogrammes each, about 40 grammes of ultramarine is sufficient. This quantity, which gives about 6 centigrammes to a loaf, is enough to communicate the very slight blue tint required. Ultramarine is perfectly innocuous.

The first invention of the process of procuring alum by artificial means is not known, but it appears to have originated in the East soon after the twelfth century. In the fifteenth century there were alum works at Constantinople.

WAGES MOVEMENT IN THE ENGINEERING TRADE.—A meeting of men employed in this trade was held last Tuesday evening, at Wilcock's rooms, Westminster-road, for the purpose of considering the best means of obtaining an advance on the present rates of wages. After some discussion, it was resolved that the advance to be asked for should be ten per cent on the present rate of wages. It was also resolved that district meetings should be held throughout London, so that the whole of the trade should be embraced in the movement. A committee was then appointed to carry on the agitation, consisting of delegates from the principal shops in the trade, and subscriptions are to be received from each district to pay the expenses of the movement. The present movement has taken place against the wish of the officials of the society.

We mentioned last week that, at the moment of going to press, we had received a communication from the solicitor of Messrs. Holtzapffel and Co. respecting certain alleged infringements of their copyright in the late Mr. Charles Holtzapffel's work on Turning and Mechanical Manipulation, and at the same time promised a full apology, should we upon examination find that we had been led to any infringement of their rights: we have since made an examination into the circumstances, and deeply regret to find that we have been most seriously misled by a contributor upon whose good faith we implicitly relied, but who has, unfortunately for ourselves, supplied us with extracts from Holtzapffel's "Mechanical Manipulation," in place of original articles as we supposed them to be. Under these circumstances there is but one course that would be followed by any respectable journal, namely, to offer every apology and amends in our power for the infringement which has most assuredly been entirely unintentional upon the part both of the management and proprietors of this journal.

KIRKALDY'S IRON AND STEEL TESTING WORKS.

The immense extent to which iron is now employed in buildings of all descriptions in the metropolis, has induced Mr. Kirkaldy, author of the well-known work on iron testing* to erect in The Grove, Southwark, works for testing materials and details. The machinery has been constructed from Mr. Kirkaldy's designs, by Greenwood and Batley, of Leeds, and is adapted for any kind of strain-pulling, crushing, beating, twisting, shearing, punching, bulging, buckling, collapsing, or bursting—well exhibited by our illustrations; and this to any amount, from 10lbs. to 1,000,000 lbs. It will also test specimens of substances as well as manufactured articles; and will, as required, ascertain the ultimate breaking strain or any lowered amount of proof strain. There can be little doubt but that engineers, architects, ship and bridge builders, boiler-makers, and others, will find Mr. Kirkaldy's apparatus advantageous in determining the best proportions in structural details, as well as the materials and variety of materials adapted to their different requirements.

Among the first works subjected to the operation of the apparatus was the patent girder of the Messrs. Phillips, of the Coal Exchange. Of this girder we may remark, in passing, that its peculiarity consists in the flanges being rolled solid, instead of being rivetted, as heretofore, whilst the web is somewhat thicker than usual. In the trials the first experiment was with a light girder, 8 inches deep, with 2½ inch flanges, and 20 ft. between the supports; the weight was 22 lb. per foot run, the iron equal to ordinary Staffordshire plate. The breaking weight of an ordinary similarly sized girder is about four tons. At seven tons the supports of the new girder gave way, and it turned over in the groove of the machine. On examination, though considerable vertical set was found, there was no fracture. Other experiments were equally favourable to the Phillips' girder.

In the illustrations, as noted (the arrows exhibiting the directions of the strain, and the specimens as before and after the strain), Figure 1

exhibits the tensile strain—or that applied to chain and other links, springs, bars, angle iron, wires of various kinds, up to any length—Fig. 2 exhibits

the crushing strain, applied to pillars, walls, &c.; Fig. 3, the bending strain, applied to girders,

joists, rails, &c.; Fig. 4, the twisting strain, for

* Results of an Experimental Enquiry Into the Comparative Tensile Strength and Other Properties of Various Kinds of Wrought Iron and Steel. London, 1862.

crank axles, and shafting, &c.; Fig. 5, the shearing

strain—sufficiently explained in the figure—as are

also Fig. 6 (the punching strain), and Fig. 7, that

for bulging. Fig. 8 exhibits the buckling strain

as applied to a ship's plate. Fig. 9, the collapsing

strain, applied to boiler tubes or others exposed to external pressure. Fig. 10 represents the effects of

the bursting strain, usually applied to boilers, or to any hollow vessel subjected to internal pressure, as waterpipes, steam pipes, gauges, &c. The apparatus is adapted to many other strains which need not be here specified. We think these illustrations are so self-explanatory as not to require any further elucidation. The contrast between the perfect and imperfect material is exceedingly striking and truthful. We now turn to Mr. Kirkaldy's work itself, having no doubt that the following particulars respecting the properties and management of wrought iron and steel, will be found highly interesting and useful to a great number of our readers. They are extracted from a work written by Mr. David Kirkaldy (above referred to), who carried out an elaborate series of experiments to ascertain the comparative tenacity and other properties of iron and steel.

As Mr. Kirkaldy observes, "It seems remarkable that whilst we have the results of many important and reliable experiments on cast iron, extremely few have been made, or at least published, on wrought iron, and almost none on steel." The conclusions therefore, drawn from the results of his own carefully conducted experiments, which in some instances do not altogether agree with several generally received opinions, will no doubt be acceptable to many who may not have had an opportunity of reading the work. Mr. Kirkaldy's book contains a number of well arranged tables with suitable remarks upon them, and the opinions of many eminent engineers on the points under investigation. Dr. Percy mentions the work in the following terms: "An excellent digest of information published on this subject is contained in Mr. David Kirkaldy's recent valuable work on the tenacity, or, as it is now termed, *tensile strength* of iron and steel; and the author appears to have arrived at nearly the same conclusions as myself," and further on in a note,† "This excellent work ought to be in the possession of every civil engineer."

The conclusions drawn by Mr. Kirkaldy from the results of his experiments are as follow:—

1. The breaking strain does not indicate the quality, as hitherto assumed.
2. A high breaking strain may be due to the iron being of superior quality, dense, fine, and moderately soft, or simply to its being very hard and unyielding.
3. A low breaking strain may be due to looseness and coarseness in the texture, or to extreme softness, although very close and fine in quality.
4. The contraction of area at fracture, previously overlooked, forms an essential element in estimating the quality of specimens.
5. The respective merits of various specimens can be correctly ascertained by comparing the breaking strain jointly with the contraction of area.
6. Inferior qualities show a much greater variation in the breaking strain than superior.
7. Greater differences exist between small and large bars in coarse than in fine varieties.
8. The prevailing opinion of a rough bar being stronger than a turned one is erroneous.

* Metallurgy of Iron and Steel, London, 1864.

† Ibid, note 11, p. 862.

9. Rolled bars are slightly hardened by being forged down.

10. The breaking strain and contraction of area of iron plates are greater in the direction in which they are rolled than in a transverse direction.

11. A very slight difference exists between specimens from the centre and specimens from the outside of crank-shafts.

12. The breaking strain and contraction of area are greater in those specimens out lengthways out of crank-shafts than in those cut crossways.

13. The breaking strain of steel, when taken alone, gives no clue to the real qualities of various kinds of that metal.

(To be continued.)

KING, SMITH, & HOWELL'S (HARTFORD STEEL WORKS, SHEFFIELD) PATENT IMPROVEMENTS IN THE REVERSING AND EXPANSIVE WORKING OF STEAM ENGINES.*

The problem of the advantageous use of the steam evaporated by the boiler being almost wholly centred upon the mechanical arrangement used for admitting the steam to the cylinder, it does not seem remarkable that a great amount of attention should have been paid to make so essential a part as perfect as possible, and in no case is this so much exemplified as in the history of the locomotive engine. Upon its first introduction, it was found that the plan then known of shifting an eccentric round upon the shaft, to reverse, was unequal to the requirements of the case in question; and the field being open, many applications were made for the protection of inventions to effect this purpose, but it was not till the year 1839 that anything of a promising nature was produced. In this year Mr. Dodds took out a patent for shifting an eccentric across the shaft by means of a wedge motion; but he does not appear at this time to have been aware that a slight modification in the arrangement would have placed him in possession of a motion theoretically superior to the link motion brought out four years later, and which only required to be worked out into a practical form to make it superior to what has been well called a princely motion. The discoveries of the important qualities of Howe's link as a valuable expansive gear, its superiority above all others, its various forms, and its universal applications in practice, are so well known, that it will be unnecessary to refer to them in the present article, the object of which is briefly to investigate the properties of a stud pin, or single eccentric thrown out of centre and shifted straight across the crank shaft, and then to explain the mechanical arrangement, based upon the principle of differential motion, invented and patented by us for effecting this purpose, both in marine and stationary engines; also to show how a correct exhaust may be given to the steam in the cylinders when the valve is worked by the link, or by any other motion having similar properties.

To avoid as much confusion as possible, we will suppose throughout that the outside lap on the valve is equal to the width of the port, which we will take at 2 inches, but that there is no inside lap; so that when the valve is in the centre of its travel a motion either way will allow the steam to exhaust, and that the maximum travel that can be given to the valve will equal 8 inches.

Diagram 1 represents a valve of the above proportions worked by a stud pin, *s*, in which the steam is just being admitted to the port, *P*, the crank, *C*, being at the dead centre, and the engine running in the direction indicated by the arrow. When *s* was at *r* the valve was in the centre, and the lap being equal to 1 inch, or one-fourth the travel of the valve, that distance must be moved through by the valve to open the port previous to the time the crank arrives at its dead centre; this will require *s* to be placed 120° in advance of the crank. By following the

motion of *s* during the next 60°, when it will have arrived at *r*, the port will be wide open, after which the valve will begin to close the port, and will have completely closed it when *s* arrives at *u*, a point corresponding to *s*, but on the opposite side of *C*, *r*, the steam having been admitted to the cylinder during the time that the crank has been running through 120°, or, disregarding the small difference produced by the connecting rod, three-quarter stroke of the piston; by continuing to follow the motion of *s* till it arrives at *v*, when the valve is in the centre of its stroke, the exhaust will take place, the crank having moved through 150°, or after nearly 15-16ths of the stroke has been completed, and at the same time the steam will be cushioned on the other side the piston.

If, while the crank is in the position shown, *s* is moved across the straight line *s u*, but a very slight motion would be given to the valve, which for all practical purposes might be regarded as nothing. Let *s* be moved down till it corresponds to a position answering to 180° in advance of the crank, this will shorten the travel of the valve, but the lead will remain the same; the port will then be widest open after 45° and closed again at 90° of movement of

position the action of *s* or *u* would preponderate in the same ratio as it does when *s* occupies any correspondingly intermediate position upon the straight line, *s u*; and by bearing this in mind it is easy to point to the position in the link corresponding to any place that might be selected as the point of cut off, which we shall require to do hereafter.

What effect is produced by the varying angularity of the eccentrics will be shown when we come to make a comparison between the single eccentric and the link motion; but we will now proceed to describe the mechanical contrivance proposed by us for shifting the stud pin, or single eccentric, across the shaft, in large classes of engines where great power is required to move the valves.

Figs. 1, 2, 3, and 4 show different views of an arrangement in which the shifting eccentric is used, and fig. 5 an arrangement where the stud pin is made to answer the same purpose; but the principle employed in both cases being the same, fig. 5 will best answer the purpose of a general explanation, being on an enlarged scale. *r* is the one end of the crank shaft of an engine, the opposite end of which is supposed to be in connection with the screw or other machinery which the engine may be driving.

crank, which would correspond to one-half stroke of piston, by this alteration cutting the steam of one-quarter stroke earlier than before; but at the same time, the exhaust will take place earlier, or after the crank has passed through 135°, or about 6-7ths of the stroke of the piston. Again, by shifting the stud pin to 175° in advance of the crank, the port will be widest open after 5° and closed again at 10° after the piston had passed through 1-130th of its stroke, but the exhaust will take place a little after one-half stroke.

If the pin, *s*, is now moved across *C r* until it arrives at *u*, and is there fixed, it will be evident that to open the port at all the engine must run in a contrary direction to what it did when *s* was on the other side of *C r*, and this will be the case when *s* holds any intermediate position between *u* and *C r*. That this will be a similar motion communicated to the link by the action of two eccentrics occupying the extreme positions, *s* and *u*, of the stud pin—that is, if the irregularity produced by eccentric rods is neglected—will be apparent when it is considered that the link itself is a vibratory lever, from the ends of which a motion is given to the valve equal in every respect to that produced by the stud pin when in the positions *s* or *u*; while in any intermediate

Upon the spare end a wrought iron piece, *FG*, is either bolted or fastened by means of a cottar, and upon this piece is fitted the whole of the improved motion. Through *o* a slot is cut, into which the sliding piece carrying the stud pin, *s*, is fitted, and which is capable of sliding backwards and forwards upon *g* to such an extent as to allow the stud pin, *i*, to occupy positions corresponding to *s* and *u* (diagram No. 1). The screw, *s*, which is the medium through which the movement is effected, passes through the centre of both the cog wheels, *c* and *d*. *d* has a boss made sufficiently long to pass through *F*, into which a thread is cut, and through which screw, *s*, passes, answering the duty of a nut; the other wheel, *c*, has a feather, *z*, let into it, which fits into a slot shown upon the screw, which will oblige the screw to turn whenever *c* turns. The two wheels, *c* and *d*, gear into *a* and *b*, which are fitted loose upon the shaft, but independently one of the other, which will enable them to be held from turning while *F* is turning round with the end of the screw shaft. This is done by means of the end of the hand wheel shaft and pinion, *v*, which are pushed forward, the end of the shaft slipping into the slots in the washer, *x*, which will stop *b* from turning; and *a* is prevented from doing the same by

* Communicated by Mr. HENRY J. H. KING, Mechanical Engineer, to the *Practical Mechanic's Journal* for December.

the pinion, F, which gears into it. The two pair of wheels, *a* and *c*, and *b* and *d*, bear the same ratio one to the other; and *a* and *b* being fixed, *c* and *d* will make an equal number of revolutions, giving us the case of a nut upon a screw turning at a uniform rate; and while they remain as they are, the stud pin will remain in an unaltered position. But if we now want the point of cut off to be varied, or the engine reversed, we have only to turn the hand wheel, *h*, which will turn *a*, whilst *b* remains stationary, producing a differential motion upon *c* and *d*, and making the nut wheel either run faster or slower than the screw wheel, and a transverse motion will accordingly be produced, shifting the stud pin, if continued long enough, to the other side the centre of the shaft, and reversing the engine.

(To be continued.)

THE FEED APPARATUS OF BOILERS.

The Giffard Injector which has been sought to be applied to the purpose of filling or supplying locomotive and other boilers with water has travelled a thorny path since the time of its discovery. This is no doubt owing to the great mystery which has seemed to be associated with the instrument itself. It is at first sight paradoxical that steam issuing from the steam space of a boiler can retain sufficient force to force water into the bottom of the same boiler from which the steam is issuing to perform the work. This fact has had a sort of perpetual-motion look about it which has seriously operated against a proper investigation of the real qualities of the injector. But it results upon examination that, not only may this be the case, but that a donkey engine working at 30lb. may force a supply of water into a boiler which is giving off steam at 60lb., and consequently affording this resistance to the entry of the supply of water. The operation of pumps in connexion with steam apparatus is a matter of continual anxiety. This is the case even with stationary as well as with locomotive engines, but it seems that pumps are inseparable from the system of marine locomotion. Owing to the unequal and sometimes sudden motions of a vessel at sea, the operation of the injector, its direction, and velocity, are affected. All that is necessary therefore is to enclose this, and give it some particular direction, which is into the boiler. This is accomplished in the following way by the Giffard Injector. A communication is made from a water supply not more than 5 or 6 feet beneath the boiler to the injector. The injector is practically two tubes of about 6 or 12 inches each in length, their diameters at one end being larger than at the other, their smaller diameters are adjusted at a trifling distance apart, so that a current of water could play from one into the other. The upper tube is called the combining cone, and the lower the receiving cone. The water is allowed to flow round the locality at which they are separated, and may be supposed to have a level two inches up the combining or top cone through which the steam passes to force the water through the aperture of the lower cone, and so on, by a conducting pipe into the bottom of the boiler. A plug is inserted in the top cone tapering towards the end, so that by elevation or depression it could entirely control the steam force and water supply by stopping up the aperture of the top cone at its lower diameter; these mechanical conditions are of course protected by a strong metallic casing. The steam is then admitted in the top cone, forcing away the residual water is interfered with, the current of the water supply being continually broken like the breaking of a current of electricity. But in the working of land engines, where the pump is a source of perpetual annoyance, it appears unquestionable that the injector could be applied with considerable advantage. It is well known that in the locomotive system the repair of pumps alone forms a large item in the cost of working, besides the continual and anxious watching they require while in operation. But in the case of an injector attached to a boiler it may be so regulated that no excess or want of water can take place. Applied to a good working boiler and engine the injector seems to represent that one function which confers upon an inanimate and material system of motion the same qualities as though they had proceeded from some living organization.

The great objection which appears to stand in the way of its general adoption is that of the so-called mystery of its operation. In the way of illustration, if it could be supposed that a common hour glass could act as well horizontally as it does vertically we would reach in a certain measure an ocular proof of injection. In the steam injector, the velocity of steam passing over a tube standing upright in water would from sympathy cause the water to ascend the tube, and a small quantity of it to partake of causing a vacuum in the supply pipe leading to the source of

the water, owing to the great velocity at which it escapes at an outlet provided for the purpose of setting the injector in motion. The water then rises up the tube, and finds a direction towards the point where the two cones are separated, where the steam acts upon it, forcing it into the underneath cone, and away on into the boiler.

LENOIR'S GAS ENGINE
